WITH SUPPLEMENT.

VOLUME XVI.
TROMBONE—ZYMOSIS.

NEW YORK:
D. APPLETON AND COMPANY,
1, 3, AND 5 BOND STREET.
LONDON: 16 LITTLE BRITAIN.
1883.

Entered, according to Act of Congress, in the year 1863, by D. APPLETON AND COMPANY, in the Clerk's Office of the District Court of the United States for the Southern District of New York.

Entered, according to Act of Congress, in the year 1876, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

Entered, according to Act of Congress, in the year 1880, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

Entered, according to Act of Congress, in the year 1883, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

THE

AMERICAN CYCLOPÆDIA.

TROMBONE, a brass wind instrument, supposed to be identical with the ancient sackbut, which constitutes one form of the trumpet. By means of sliding tubes great depth and power of tone are produced, and the instrument is capable of splendid effect. Trombones are of three kinds, alto, tenor, and bass; the first having a compass from C, the second space in the bass, to G, an octave above the treble clef; the second from B, the second line in the bass, to A, the second space in the treble; and the third from C, an octave below the second space in the bass, to G, the second line in the treble.

TROMP. I. Maarten Harpertzoon van, a Dutch admiral, born in Briel in 1597, killed in battle, July 31 (N. S., Aug. 10), 1653. In his boyhood he was captured by the English in a battle off the Guinea coast, in which his father was killed. Subsequently he was prominent on various occasions, especially under Admiral Heijn. In 1639, as admiral of Holland, he inflicted great damage upon the Spanish fleet near Gravelines, and in October he gained a most decisive victory over a powerful Spanish squadron under Oquendo in the Downs, for which he was made a noble of France. Against the English fleet in 1652 he was at first unsuccessful in the Downs, and was superseded by De Ruyter, but was soon reinstated as chief commander. He signally defeated Blake near the Goodwin Sands, Nov. 29, but was intercepted by him off Portland island, Feb. 18, 1653, suffered a heavy loss, and retreated. He was killed in an encounter off the Dutch coast with the English fleet under Monk, and was buried with great splendor at Delft. **II. Cornelis van,** a Dutch admiral, son of the preceding, born in Rotterdam, Sept. 9, 1629, died in Amsterdam, May 29, 1691. He early operated against the African pirates and against the English in the Mediterranean, and when 21 years old was made vice admiral. From 1656 to 1662 he lived in retirement. In 1665, when the Dutch fleet under Admiral Opdam was beaten by the English off Solebay, Van Tromp conducted a masterly retreat. He was appointed commander-in-chief in the absence of De Ruyter, and under him he displayed great valor in the encounter with the English in the Downs in June, 1666; but on July 25 (N. S., Aug. 4) he was cut off from the main squadron, and was unable to come to the relief of De Ruyter, who accordingly insisted upon his removal. He was reinstated in 1673, during the war with the allied French and English, in which he gained new laurels. After the restoration of peace with England in 1675 he was cordially received in that country, and Charles II. made him a baronet. On De Ruyter's death in 1676 he succeeded him in the highest naval rank, but afterward served for some time with great distinction under the Danish government.

TROMSÖ. I. The northernmost stift or diocese of Norway, bordering on the Arctic and Atlantic oceans; area, 42,687 sq. m.; pop. in 1865, 155,335. It is divided into the bailiwicks of Nordland, Tromsö, and Finmark, and includes the Loffoden islands, celebrated for magnificent scenery and extensive cod and herring fisheries. (See Loffoden.) There is little agriculture, the main means of subsistence being derived from fisheries. **II.** A town, capital of the diocese, on an island in the sound of Tromsö, between the island of Kvalö and the mainland; lat. 69° 38′ N., lon. 19° E.; pop. about 4,000. It is the seat of a governor, and has several schools, a church, a Lappish printing office, and a hospital chiefly for lepers. The seat of the bishop has been removed to Alstahoug. The town was founded in 1794, and has an active shipping trade and an excellent harbor sheltered by mountains. Many vessels belonging here are engaged in the walrus fishery at Nova Zembla and Spitzbergen.

TRONDHJEM, or Throndhjem. See Drontheim.

TROOPIAL (Fr. *troupiale*), a name given to several species of the *icterinæ* and *agelainæ*, subfamilies of American conirostral birds, in some respects resembling the starlings of the old world, and in others coming near the finches; they have the nine primaries of the finches, but the bill is larger, straight, the base without bristles, and the tip without a notch. The name is derived from their habit of associating in large troops. In the *icterinæ* the bill is generally longer than the head, straight and sharp-pointed; wings long and pointed, and tail usually wedge-shaped; toes moderate and formed for perching. The prevailing colors are yellow or orange and black; they are generally called orioles in North America, and a well known species has been described under Baltimore Bird; hang-nest is a name derived from their habit of suspending the nest from the extremity of slender branches.—The common troopial (*icterus vulgaris*, Daud.) is about 10 in. long, with a straight bill; back and abdomen yellow; head, neck all round, breast, and tail black; a white band on the wings; feathers of throat elongated and pointed; it is a native of northern South America and the West Indies, sometimes coming to the southern United States. They move in flocks, sometimes mingled with other species, and show a great partiality to the neighborhood of man; they are excellent fliers, and equally at home on the ground or in trees; they are loquacious at all seasons; their flesh is excellent. There are several other species in Mexico, Texas, and Central America. The orchard troopial (*I. spurius*, Bonap.) very much resembles the Baltimore oriole in the pattern of its colors, the orange red of the latter being replaced by dark chestnut, the tail entirely black and more graduated, and the bill slenderer and more curved. —The only other genus of the *icterinæ* which can be mentioned here is *cassicus* (Cuv.), so called from *cassis*, a helmet, the bill rising on the forehead in a crescent shape; nostrils basal, naked, pierced in the substance of the bill; third and fourth quills longest, and tail long and graduated; tarsi and toes strongly scaled. There are about 20 species, peculiar to tropical America, living in the forests and also near human habitations, in vast troops; they eat fruits, berries, insects, and larvæ. The nest is most ingeniously woven by both sexes, made of fibres and dried grasses, of a cylindrical or gourd-like form, and sometimes 3 ft. long; the lower part is hemispherical, the opening near the top, and the fabric suspended from the ends of slender twigs of high trees, out of the reach of monkeys and snakes; many nests are made on one tree, and sometimes those of different species together. They are docile in captivity, and learn to whistle and to articulate words; they are generally black, contrasted with bright yellow, especially toward the tail.—In the subfamily *agelainæ* the bill is stout, short, conical, nearly straight, and sharp-pointed; tarsi as long as the middle toe; toes long and slender, and claws long and curved. Some of the birds of this subfamily have been described under Blackbird, Bobolink, and Cow Bird, species respectively of the genera *agelaius* (Vieill.), *dolichonyx* (Swains.), and *molothrus* (Swains.).

Common Troopial (Icterus vulgaris).

Cassican (Cassicus).

TROOST, Gerard, an American chemist and geologist, born in Bois-le-Duc, Holland, March 15, 1776, died in Nashville, Tenn., Aug. 14, 1850. He was educated at the university of Leyden, and in 1809 was sent by Louis Bonaparte, king of Holland, on a tour of scientific observation in Java. The capture of the vessel by a privateer interrupted this undertaking, and in 1810 he settled in Philadelphia. He was one of the founders of the academy of natural history, and its first president from 1812 to 1817. In 1814 he established the first alum works in the United States; and in 1825, having held for a short time the professorship of chemistry in the college of pharmacy in Philadelphia, he joined Robert Owen's community at New Harmony. In 1828 he was appointed professor of chemistry, mineralogy, and geology in the university of Nashville, and in 1831 geologist of the state of Tennessee. He published reports on the geology of Tennessee, and memoirs on geology and mineralogy.

TROPÆOLUM. See Nasturtium.

TROPIC BIRD (*phaëton*, Linn.), a genus of web-footed oceanic birds, constituting the family *phaëtonidæ*. They have a long, strong, pointed bill, broad at the base, slightly curved, without nail and the edges finely serrated;

nostrils at base of bill, lateral, and pervious; face covered with feathers; wings long and pointed, the first primary the longest; tarsi short and strong, feet small, and toes fully webbed; hind toe small; tail with two long, straw-like feathers, whence the French name *paille en queue* or straw-tail; sailors call them boatswain bird and marlinspike. In habits and appearance they come near the gulls and terns; they are chiefly confined to the tropics. Their powers of flight are great, and they are usually seen at considerable distances from land; they live almost entirely on the wing, and, when they do not return to the distant shore to roost, rest upon the surface of the ocean; they are excellent swimmers. The food consists of fish and other marine animals, which they dart upon from a great height; they are fond of following the shoals of flying fish, seizing them as they emerge from the sea. They are not larger in the body than a pigeon, though longer; they congregate in considerable numbers at their breeding places, on rocky shores and desert islands, placing the nest on the ground or in holes in trees; the eggs are two; their flesh is fishy and tough. The common tropic bird (*P. æthereus*, Linn.) is about 30 in. long and 38 in. in alar extent; it is of a satiny white, the wings banded with black, and the head, back, and wings tinged with cream color or light pink; first five primaries black on the outer webs, and the shafts of the long tail feathers black to near the end, where they are white; a black mark over eyes to occiput; bill orange red and iris brown; tarsus and toes yellow at base, webs and claws black. It sometimes comes near the Florida coast, but is usually seen in the tropical Atlantic far from land. The long tail feathers of the *P. phœnicurus* (Gmel.), inhabiting the tropical Pacific, are bright red, and are used as ornaments by the South sea islanders.

Tropic Bird (Phaëton æthereus).

TROPICS (Gr. τροπή, a turning), in astronomy, two circles parallel to the equator, at such distance from it as is equal to the greatest recession of the sun from it toward the poles, or to the sun's greatest declination. That in the northern hemisphere is called the tropic of Cancer, and that in the southern the tropic of Capricorn, from their touching the ecliptic in the first points of those signs. (See Cancer, and Capricorn.) It is between the tropics that the sun's path is circumscribed, its annual movement being from one to the other and back again in the ecliptic.—In geography, the tropics, also known as that of Cancer and that of Capricorn, are the two parallels of latitude (about 23° 28′ N. and S.) over which the sun is vertical at the solstices. (See Solstice.)

TROPLONG, Raymond Théodore, a French jurist, born at St. Gaudens, Haute-Garonne, Oct. 8, 1795, died in Paris, March 2, 1869. He early held important judicial offices. In 1846 he was made a peer, in 1848 first president of the court of Paris, and in 1852 of the court of cassation. In 1852 he was made a senator, and in 1854 president of the senate. His principal work, *Le Code civil expliqué* (28 vols., 1833–'58), is a collection of treatises in continuation of Toullier's *Commentaire du Code civil*, many of which have been published separately.

TROPPAU, a city and the capital of Austrian Silesia, on the Oppa, 35 m. N. E. of Olmütz; pop. in 1870, 16,608. It has six Catholic churches, a palace, a gymnasium with a large library, a museum, and manufactories of beet sugar, flax, and cloth. A congress of sovereigns was held here from Oct. 20 to Dec. 20, 1820, preliminary to that of Laybach.—The former duchy of Troppau, having been divided into the principalities of Troppau and Jägerndorf, was partly annexed to Prussia in Frederick the Great's conquest of Silesia, and forms the S. W. part of Prussian Silesia, with Leobschütz, of the Jägerndorf division, as capital. The territory which remained to Austria after the peace of 1763 constitutes most of the N. part of Austrian Silesia, comprising, besides the capital, Jägerndorf and other manufacturing towns.

TROUBADOURS. See Provençal Language and Literature.

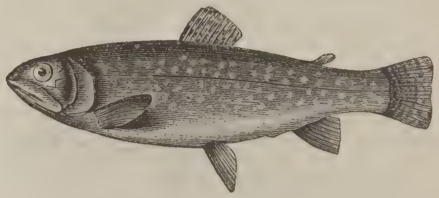
TROUP, a W. county of Georgia, bordering on Alabama, and intersected by the Chattahoochee river; area, about 370 sq. m.; pop. in 1870, 17,632, of whom 11,224 were colored. The surface is hilly and the soil generally fertile. It is intersected by the Atlanta and West Point railroad. The chief productions in 1870 were 26,645 bushels of wheat, 162,946 of Indian corn, 34,514 of oats, 29,290 of sweet potatoes, and 9,963 bales of cotton. There were 680 horses, 1,698 mules and asses, 1,519 milch cows, 3,027 other cattle, 1,203 sheep, and 6,516 swine; 1 manufactory of boots and shoes, 2 of cotton goods, 1 of iron castings, 2 of machinery, and 3 saw mills. Capital, La Grange.

TROUP, George McIntosh, an American statesman, born on the Tombigbee river, Sept. 8, 1780, died in Laurens co., Ga., May 3, 1856. He graduated at Princeton college in 1797, was admitted to the bar, and at the age of 21 was elected to the state legislature. Between 1807 and 1815 he was a representative in congress from Georgia, and in 1816 was elected a United States senator. From 1823 to 1827 he was governor of the state, and in 1829 was a second time elected to the United States senate, from which he retired before the expiration of his term, on account of ill health. He was one of the most earnest and able of the advocates of state sovereignty. His life was written by E. J. Harden (Savannah, 1859).

TROUSDALE, a N. county of Middle Tennessee, intersected in the S. E. by the Cumberland river; area, about 110 sq. m. It has been formed since the census of 1870 from portions of Macon, Smith, Sumner, and Wilson counties. The greater part of the surface is made up of valleys separated by ridges, the soil of both being productive. The timber consists of poplar, white oak, walnut, &c., but is not abundant. Blue grass is abundant. The staples are corn, wheat, tobacco, and hay. Capital, Hartsville.

TROUSSEAU, Armand, a French physician, born in Tours, Oct. 14, 1801, died June 23, 1867. He graduated in medicine at Paris in 1825. In 1828 he was sent by government to investigate endemic and epidemic diseases prevalent in the central departments of France, and the yellow fever at Gibraltar. In 1831 he was appointed hospital physician; in 1837 he received the grand prize of the academy of medicine for a treatise on *phthisis laryngea;* and in 1839 he was appointed professor of therapeutics and materia medica in the faculty of medicine. He was prominent in introducing and establishing the practice of tracheotomy in croup and *paracentesis thoracis* in cases of dangerous or long continued pleuritic effusion. His most important works are *Traité élémentaire de thérapeutique et de matière médicale* (Paris, 1836; 8th ed., 2 vols., 1867), which was translated into English, Spanish, and Italian, and *Nouvelles recherches sur la trachéotomie dans la période extrême du croup* (1851).

TROUT, a name popularly restricted to the species of the salmon family inhabiting exclusively or principally fresh water, and embracing members of the three subgenera of the old genus *salmo* made by Valenciennes, viz., *salmo*, *fario*, and *salar;* the family characters have been given under SALMON. The salmon trouts belong to the genus *fario* (Val.), having one row of teeth on the vomer, the true salmons having the palate smooth; the species are so called from the redness of the flesh, but all the trouts have this color at some epoch of their lives, depending probably on their food. The salmon trout of Europe (*F. argenteus*, Val.; *salmo trutta*, Linn.), called also white or sea trout, is found in the larger lakes and rivers of that continent; it varies considerably in color, like all of the family, according to the character of the water and the quality of the food; it is greenish gray or bluish black above, lighter on the sides, and silvery white below, with a few black spots above the lateral line; it attains a length of 2 to 2½ ft., and, being abundant in the markets of London and Paris, is next in value to the salmon, which it resembles in habits. The so-called sea trout of the gulf of St. Lawrence (*salmo immaculatus*, H. R. Storer) has the flesh of a fine pink color and superior flavor; the color is sea-green above, lower parts and the fins white; it rarely exceeds a weight of 7 lbs.; it probably belongs to the genus *fario.* There are several species called salmon trout in lakes shut off from the sea and near the mouths of the rivers of Maine. The spots of trout resist the action of heat and even of alcohol for a long time.—The common brook or speckled trout of North America (*salmo fontinalis*, Mitch.) is from 8 to 20 in. long, pale brownish above with darker reticulated markings; sides lighter, with numerous circular yellow spots, many with a bright red spot in the centre; white or yellowish white below; the first ray of pectorals, ventrals, and anal edged with white and black, with the rest of these fins reddish. It is found abundantly in the streams of the British provinces, the New England, middle, and western states, and is everywhere highly esteemed as food; it is rarely taken weighing more than 1½ lb.; the markings vary considerably according to locality and season; in New Brunswick and Nova Scotia it descends to the sea when it can; it is the same species from Labrador to Pennsylvania and Ohio. It is a great favorite with anglers; it is taken by the hook and line baited with a minnow, shrimp, worm, or artificial fly; in narrow streams, just before the spawning season, when it is little inclined to bite, it may be caught by titillation, by passing the hand carefully under the tail, and, as the tickling is gently performed, slowly moving it toward the head, until by a sudden grasp it is seized and landed.—In the genus *salmo* belongs also the char of the British and Swiss lakes (*S. umbla*, Linn.), usually 9 to 12 in. long, but sometimes 18 or 20 in.; it is umber-brown above, the sides lighter with numerous red spots, the lower parts and fins reddish orange; it varies like all other trouts, and occasionally attains a larger size than the above; it frequents the deep part of the lakes, feeds chiefly at night, and affords but little sport to the angler. Its American representative is the *S. oquassa* (Girard) of the great lakes of Maine.—In the genus *salar* (Val.) there are two rows of teeth on the vomer. The common European brook trout (*salar fário*, Val.) is usually 10 to 14 in. long, though sometimes considerably larger, even to a weight



Speckled Trout (Salmo fontinalis).

of 15 lbs.; it is shorter and stouter than the salmon, yellowish brown above, passing to yellow on the sides, and silvery below, the back spotted with reddish brown and the sides with bright red; the young are transversely banded; deformed specimens are frequently seen. The colors are brightest in rapid streams with rocky or gravelly bottom; the flavor is finest from the end of May to the end of September, soon after which the spawning season begins. This species is highly prized by anglers, and especially fly-fishers. As it is fond of swiftly running waters, and swims almost always against the current, the bait must be thrown up stream. The eggs are deposited in nests or holes in the sand, as with the salmon. The gray trout of the North American great lakes, from the northern United States to the Arctic ocean, is the *S. namaycush* of Valenciennes, and the *salmo amethystus* of Mitchill and De Kay; it is called togue by the Canadian lumbermen, and from its size and voracity the tyrant of the lakes; it is greenish ashy above with yellowish gray spots, and below white with bluish reflections; the average weight is 12 to 20 lbs., though it attains sometimes more than twice this size. The siskiwit (*S. siscowet*, Ag.) belongs to the genus *salar* (Val.); it is of large size, stout and thick, of a rich flavor, but so fat as to be almost unfit for food; for description and figure see Agassiz's "Lake Superior," p. 333 (8vo, Boston, 1850).—The trout, both in Europe and America, is a favorite subject for pisciculture, from the ease with which artificial fecundation of the eggs can be effected; but it has as yet been practised here on a small scale only; the labor and expense attending a large vivarium of trout are very small, while the remuneration may be made very large. For an illustrated account of the manner of hatching trout artificially, see "American Naturalist," vol. iii., p. 202, and vol. iv., p. 601 (1870).

TROUVILLE, a French watering place, in the department of Calvados, Normandy, prettily situated at the foot of a hill near a forest, at the mouth of the Touques in the English channel, 107 m. W. N. W. of Paris; pop. in 1872, 5,761. Until recently it was a small fishing village. The bathing season begins in June, and lasts till the middle of October. Deauville, a rival watering place, is on the opposite bank.

TROVER (Fr. *trouver*, to find), the name of an action at law in common use in England and in the United States, to determine the ownership of property. The plaintiff declares, in substance, that he was lawfully possessed of a certain article on a certain day, and lost the same; that it came into the possession of the defendant by finding; and that the defendant has refused to deliver it to the plaintiff, and has converted it to his own use. This action is one form of trespass on the case. (See TRESPASS.) In the distant age when it was first used, the declaration may have narrated accurately the facts of the case; but for a long time the losing and finding have been regarded as mere legal fictions, which the defendant is not at liberty to deny. The action is maintainable: 1, where the property in question is a personal chattel; 2, where the plaintiff had a general or special property in the thing with a right of possession; 3, where the defendant has wrongfully converted the thing to his own use, which conversion may be proved by his wrongful taking of it, or his wrongful detention of it, or his wrongful use or misuse of it. The action demands not the thing itself, but damages for the wrongful conversion; and if the plaintiff recovers, the damages should be measured by the value of the thing at the time of the conversion, with interest, and the judgment is for these damages and costs.

TROWBRIDGE, John Townsend, an American author, born in Ogden, Monroe co., N. Y., Sept. 18, 1827. At the age of 20 he went to Boston, connected himself with the public press, and became known as a writer of popular stories. With Lucy Larcom he edited "Our Young Folks" till January, 1874. He has published "Father Brighthopes, or an Old Clergyman's Vacation," "Burr Cliff, its Sunshine and its Clouds," and "Hearts and Faces" (1853); "Martin Merrivale, his X Mark" (1854); "Iron Thorpe" (1855); "Neighbor Jackwood" (1857); "The Old Battle Ground" (1859); "The Drummer Boy;" "The Vagabonds" (1863, and with other poems, 1869); "Cudjo's Cave" (1864); "The Three Scouts" (1865); "Lucy Arlyn," "Coupon Bonds," and "The South: a Tour of its Battle Fields and Ruined Cities" (1866); "Neighbors' Wives" (1867); "The Story of Columbus" (1869); "Laurence's Adventures" (1870); "Jack Hazard and his Fortunes" (1871); "A Chance for Himself" (1872); "Doing his Best" (1873); "Fast Friends" (1874); and "The Young Surveyor" (1875).

TROY (TROJA), the name of an ancient city in the N. W. part of Asia Minor, applied also to its territory. The latter, generally known as the Troad (Troas), comprised for a time the coast lands on the Propontis, Hellespont, Ægean sea, and Adramyttian gulf, as far E. as the river Rhodius, the Granicus, or even the Æsepus, but later, according to Strabo, only the region from the promontory of Lectum to the Hellespont. The city of Troy, also called Ilium (Ἴλιον), according to the Homeric poems, was situated at the foot of Mt. Ida, far enough from the sea to allow of the movements of two large armies, and in a position which commanded a view of the plain before it and of a smaller one behind it. In front of it were two rivers, the Simoïs and Scamander, flowing parallel for some distance, which united and emptied into the Hellespont, between the promontories of Sigeum and Rhœteum. This city, the existence of which is attested only by the traditions of the Trojan war, must be distinguished from the Ilium of history, which, according to Strabo, was founded about the beginning of the 7th century B. C. The former was afterward designated as Old Ilium, and the latter as New Ilium. The name was shared also by a third place in the same region, the *χώμη 'Ιλιέων*, "the village of the Ilians," about 3 m. from New Ilium, which claimed to occupy the site of the original Ilium.—According to the legend, Dardanus was the mythical ancestor of the Trojan kings, who were of the Teucrian race, closely connected with the Mysian. (See Mysia.) Dardanus's son was Erichthonius, who was succeeded by Tros, and he by Ilus, who founded in the plain of Troy the city of Ilium. Ilus was succeeded by Laomedon, and to him Neptune and Apollo became temporarily subject by command of Jupiter. The former built the walls of the city, and the latter took care of the herds; but when their time of service had expired, Laomedon treacherously refused to pay what was due them. In revenge Neptune sent a sea monster to kill the Trojans and ravage their fields, and the treacherous king in consequence made a public offer of the immortal horses given by Jupiter to Tros to any one who could rid the land of the monster. The oracle declared that a virgin of noble blood must be given up, and the lot fell on Hesione, Laomedon's own daughter; but she was rescued by Hercules, who came at this time and killed the monster. Laomedon gave the hero mortal horses, and the latter, indignant at this perfidy, collected six ships, attacked and captured Troy, killed Laomedon, and placed on the throne Priam, who alone of Laomedon's sons had remonstrated against the perfidy of his father. To him were born by his wife Hecuba a large number of children, one of whom, Paris, brought on by his abduction of Helen, the wife of Menelaus, the memorable siege of Troy. To revenge this outrage, the Greeks spent ten years in the collection of a vast armament, and at the end of that time a fleet of 1,186 ships, containing more than 100,000 men, was assembled at Aulis in Bœotia, and placed under the command of Agamemnon. The Trojans and their allies were driven within the walls of their city, and nine years were spent by the Grecian host in the reduction of the neighboring towns. But the gods now brought on the quarrel between Agamemnon and Achilles, which proved so disastrous to the Greeks, and with which the narrative of the siege in the Iliad opens. Among the principal Greek heroes in the struggle, besides Agamemnon, Menelaus, and Achilles, were Ulysses, Ajax the son of Telamon, Diomedes, Patroclus, and Palamedes; and among the bravest defenders of Troy, Hector, Sarpedon, and Æneas. The valor of Achilles, who slew Hector in revenge for the death of Patroclus, and the cunning of Ulysses finally prevailed, with the aid of Juno, Minerva, and other divinities hostile to the Trojans; and after a siege of ten years (generally placed at about 1194–1184 B. C.), Troy was utterly destroyed, Æneas and Antenor alone escaping with their families.—The opinions of the principal authorities on the question whether the destruction of Troy was a historical event have been given in the article Homer; we shall confine ourselves here to reviewing the various attempts made to identify the site of Old Ilium, on the supposition that it once existed. Though it was the popular belief of antiquity that New Ilium had been built on the ruins of the Old, yet that town never rose to importance, and Demetrius of Scepsis and Hestiæa of Alexandria maintained that the remains of Priam's Ilium were to be found rather in the "village of the Ilians," which opinion was supported also by Strabo. All were agreed that the ancient city stood on the right bank of the Scamander, the modern Mendereh. New Ilium was on the Scamander near the junction of the Simoïs, which is supposed to be represented by the Gumbrek or Dumbrek, about 12 m. long, now entering the Hellespont by a separate channel. The ruins of New Ilium are near the village of Hissarlik, on a small hill. The ancient historians Hellanicus, Xenophon, and Arrian identified this hill as the citadel of Pergamus; and Xerxes and Alexander, and the Roman consuls and emperors, here offered hecatombs to the Minerva of Ilium and the Trojan heroes. But Horace and Lucan, as well as other Roman authors, were firmly convinced that the knowledge of the site of Homeric Troy had entirely perished. In 1785 Le Chevalier discovered on the left bank of the Mendereh, near the village of Bunarbashi, about 5 m. S. of New Ilium, a hot and a cold spring or fountain, which he supposed to be those mentioned in the Iliad. Beyond these springs is a hill, the Balidagh, steep and lofty, with some ruins on its summit, which he identified with ancient Troy and the citadel of Pergamus. His view was speedily adopted by Heyne, and afterward by Welcker, J. G. von Hahn, Choiseul-Gouffier, Texier, Forchhammer, Tozer, Leake, E. Curtius, and the majority of Greek archæologists and philologists, who until recently warmly defended it as the only possible means of harmonizing the Homeric text with the chorography and topography of the Troad. But the excavations made on the Balidagh brought to light only a few terra cotta figures, lamps, pottery, and coins of no ancient date, without revealing the foundations of a town or city. In 1871–'3 the German traveller Schliemann undertook to excavate at his own expense the hill of Hissarlik. (See Schliemann.) He dug to a depth of about 50 ft., and encountered several layers of ruins, each of which he considered to be the remains of a distinct city, one built on the ruins of the other. He unearthed a vast number of arms, household utensils, and ornaments of various degrees of workmanship and kinds of material. He produced a treasure of vases and various ornaments of gold, amber, and silver, which he thinks belonged to Priam, the Trojan king. He maintains that he has laid bare the palace of this king, the Scæan gates before it, the walls of Neptune and Apollo, the streets of the city, houses which must have been two or three stories high, sacrificial altars to Minerva, and 20 fountains, besides inscriptions of various dates and in several languages and dialects. In view of the fact that but few scholars are yet inclined to consider the existence and destruction of the Homeric Ilium a historical fact, and that almost all authorities are agreed that only the Balidagh near Bunarbashi was chosen by the poet as the central scene of his epic, the results of Schliemann's excavations have so far been looked upon, if not with suspicion, yet with little confidence in the identification which he claims to have made. At present (1876) the opinion generally entertained is that he has accidentally hit upon the site of some unknown Hunnic settlement, Lydian town, or Phœnician trading post. —See Lechevalier, *Voyage de la Troade* (3 vols., 3d ed., Paris, 1802); Forchhammer, *Beschreibung der Ebene von Troja* (Frankfort, 1850); Hahn, *Die Ausgrabungen auf dem homerischen Pergamos* (Leipsic, 1865); Tozer, "Lectures on the Geography of Greece" (London, 1873); and Schliemann, "Troy and its Remains," edited by Dr. Philip Smith (1875).

TROY, a city of New York, capital of Rensselaer co., on the E. bank of the Hudson river, at the head of steamboat navigation, and also at the head of tide water, 151 m. by the course of the river N. of New York city, and 6 m. N. of Albany; pop. in 1840, 19,334; in 1850, 28,785; in 1860, 39,235; in 1870, 46,465, of whom 16,219 were foreigners, including 10,877 Irish, 1,699 British Americans, 1,576 English, and 1,174 Germans; in 1875, 48,821. The surface of the city comprises the alluvial flats three fourths of a mile wide on the river, and the hills on the east known as Mt. Ida. Wynant's Kill on the south, and Poesten Kill ½ m. N., break through these hills in narrow ravines and in a series of cascades, the former furnishing 12 mill sites with 2,000 horse power, the latter 10 sites with 1,000 horse power; while the state dam across the Hudson, at the N. part of the city, furnishes 4,000 horse power. There is also an immense amount of steam power in use. The pure water with which the city is supplied by the Troy water works is drawn from Piscawin creek into reservoirs high enough to carry the water to the top of most of the houses. A new city hall, costing $150,000, is in course of construction. The savings bank building is an elegant edifice, costing $450,000, and there are several fine business structures. Troy is situated at the principal outlet of the Erie and Champlain canals, and is connected with Lake Champlain and the north by the Rensselaer and Saratoga, and Troy and Boston railroads, the latter connecting it with the east also; with the west by the New York Central railroad; with the south by the Hudson River railroad; and with the east by the Boston and Albany railroad. There is a daily line of steamers to New York in summer. In the centre of the city is the union railroad depot, one of the largest structures of the kind in the United States, 404 by 240 ft., with walls at the sides 27 ft. high supporting the roof in a single arch. All the railroad lines centre at this depot, and 60 trains arrive at or depart from it daily. The river is spanned by a bridge 1,600 ft. long, which is provided with two carriageways, a railway, and a walk for foot passengers, and also by a new iron bridge for pedestrians and carriages, costing $250,000.—The iron manufactures of Troy are of great importance, and by means of them the city has become a controlling point in the iron interest on this side of the Alleghany mountains. One of the largest manufacturing establishments of the country is the Albany and Rensselaer iron and steel company, which owns the Albany iron works, the Rensselaer iron works, Bessemer steel works, the Fort Edward blast furnace, and the Hudson blast furnace. The company employs 1,500 hands, and produces pig iron, merchant and angle iron, merchant steel, nails and spikes, axles, bolts and nuts, boiler rivets, iron and steel rails, horse shoes, &c. The Burden iron works, established in 1813, have an annual capacity of 40,000 tons, and employ 1,400 hands, producing pig iron, merchant iron, horse and mule shoes, and boiler rivets. The other iron manufactures of the city are carried on by more than 30 firms, and consist of stoves, hollow ware, hot air furnaces, machinery, steam engines, scythes, shovels, malleable iron, safes, butts, hinges, steel springs, agricultural implements, &c. The Troy stamping works manufacture stamped and pressed wares, coal hods, shovels, dampers, &c. The Troy car works are at Green Island, a suburb on the opposite side of the river. The annual product of the shirt and collar (linen and paper) business, which is more extensive here than anywhere else in the United States, and employs more than 30 factories, is valued at $3,000,000, requiring the labor of 6,000 hands, chiefly women. The largest manufactory of mathematical instruments in the United States is in this city, as is also one of the largest of the few American globe manufactories. There are brass founderies, breweries, two distilleries, two bell founderies, a cotton mill, carriage factories, a manufactory of stoneware, and several of boots and shoes, fire brick, and hosiery. The total annual value of the manufactures of Troy is about $10,000,000. The lumber trade is important. There are ten national banks, with an aggregate capital of $2,800,000, of which four have savings departments; a state bank, with $300,000 capital; and a savings bank, established in 1823. —The city is divided into 13 wards, and is governed by a mayor and a board of 26 aldermen. It has horse railroads and a good fire department. The assessed value of property in 1874 was $15,441,845. The taxation for city purposes was $575,801 25; for state and county purposes, $284,125 22. The total funded debt was $1,226,000; net debt, less sinking fund, &c., $738,550. The principal charitable institutions are the church home, Presbyterian church home, home for aged poor, Troy Catholic male orphan asylum, Troy orphan asylum, Troy hospital, Marshall infirmary, and home of the "Little Sisters of the Poor." The public schools embrace a high school and 15 ward schools, and have an annual enrolment of about 8,000 pupils and an average attendance of 4,500. The expenditure for school purposes is from $125,000 to $150,000 a year. The Troy female seminary, removed from Middlebury, Vt., to Troy in 1821, gained a national reputation under the charge of its founder, Mrs. Emma Willard; it was discontinued in 1870. The Rensselaer polytechnic institute, endowed by Stephen Van Rensselaer, was organized in 1824, for the purpose of teaching the application of mathematics to civil engineering and the natural sciences, and has in its special departments a high reputation. In 1874–'5 it had 13 instructors, 170 students, and a library of 3,000 volumes. St. Joseph's theological seminary of the province of New York, a Roman Catholic institution, was founded at Fordham in 1841, and removed to Troy in 1864. In 1874–'5 it had 6 professors, 126 students, and a library of 8,000 volumes. The Troy young men's association for mutual improvement has a valuable library of 19,000 volumes, and a reading room. It occupies a part of the beautiful freestone building known as the Athenæum, in which is also the post office. Three daily and five weekly newspapers are published. There are 50 churches, viz.: 6 Baptist, 1 Church of Christ, 8 Episcopal, 3 Jewish, 1 Lutheran, 9 Methodist, 11 Presbyterian, 9 Roman Catholic, 1 Unitarian, and 1 Universalist.—The first house of any note on the site of Troy was built by Matthias Vanderheyden in 1752, and is still standing on the S. E. corner of River and Division streets. Between 1786 and 1790 the tract was surveyed and laid out, with streets running at right angles excepting where such plan was interfered with by the course of the river. Hitherto the place had been variously known as Vanderheyden's ferry, Ferry hook, and Ashley's ferry; but on Jan. 5, 1789, the name Troy was adopted. At this time it contained five small stores and about a dozen dwellings. The first village charter was adopted in 1791. This was superseded by another on Feb. 16, 1798, and the village was formally incorporated by state acts passed April 2, 1801, and April 9, 1805. The city charter was granted April 12, 1816. Troy has suffered by three great fires: June 20, 1820, 98 buildings, loss $490,000; Aug. 25, 1854, 300 buildings, loss $1,000,000; and May 10, 1862, 671 buildings, loss $3,000,000.

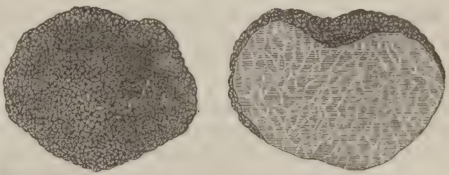
TROYES, a city of France, capital of the department of Aube, and formerly of Champagne, on the left bank of the Seine, 90 m. E. S. E. of Paris; pop. in 1872, 38,113. It has a cathedral with a celebrated choir and stained glass windows, and surrounded by five chapels, begun about 1200 and finished in the 16th century, and recently restored. The unfinished collegiate church of St. Urban, and those of St. John, St. Nizier, and the Madeleine, are likewise remarkable. The lyceum of Troyes is one of the finest in France. In the former abbey of St. Loup is an extensive collection of books and manuscripts. The museum is rich in coins and mosaics. The manufactures of cotton and woollen goods and hosiery are of great extent. Soap, sausages, and cheese are also made.—Troyes was originally the capital of the Tricasses. Under the Romans it was included in Gallia Lugdunensis, and became known as Augustobona, and in the 5th century as Trecæ. At the close of the 9th century it was devastated by the Normans. It was the seat of several councils, and under the counts of Champagne it rose in the 12th century to great importance. John the Fearless of Burgundy captured the town in 1415. The treaty uniting the French and English crowns, concluded here May 21, 1420, was sealed on June 2 by the marriage of Henry V. with the princess Catharine. During the war between Charles V. and Francis I. it was almost reduced to ashes by the former (May, 1524). In 1814 it was a prominent battle ground between Napoleon and the allies. In November, 1870, it was occupied by the Germans.

TROYON, Constant, a French painter, born in Sèvres, Aug. 25, 1810, died in Paris early in 1865. He was early employed at Sèvres in painting on porcelain, and began in 1833 to send his works to the annual exhibitions in Paris. He rose to the first rank of his profession, especially in landscapes and animals, and has been called the Lafontaine of his art. He painted many pictures illustrating Sèvres, St. Cloud, and other places near Paris. Among his animal and figure pieces are "The Fair of Limousin," "The Cattle Market," "The Watering Place," "The Poacher," "Working Oxen," "Hounds at Rest and in Motion," "Going to Market," and "Before the Storm" (a vigorously painted landscape with cattle and sheep). One of his most celebrated works, a landscape with animals, left unfinished at his death, was in 1869 presented by his mother to the museum of the Luxembourg, and placed in the Rubens gallery. Many of his pictures have been popularized by engravings. In 1875 his "Osier Bed" was sold in Paris for 24,200 francs, his "White Cow chased by a Dog" for 10,400 francs, and his "Pastures near Trouville" for 12,000 francs.

TROY WEIGHT, a scale of weights used in England and the United States for weighing gold, silver, and jewels, and in trying the strength of spirituous liquors, and legally established in both countries for determining the weight of coins. The derivation of the term is uncertain. In 1828 a standard troy pound in brass brought from England was declared by act of congress the legal standard of the United States mint. It is equal in weight to 22·815676 cubic inches of distilled water at 62° F., the barometer being at 30 inches. It contains 5,760 grains, of which 24 make a pennyweight, 20 pennyweights an ounce, and 12 ounces a pound. It is the standard of the imperial system of weights in England, and from it is derived the avoirdupois pound, which contains 7,000 troy grains; and 1 lb. avd. = 1·2152777 + lb. troy. (See AVOIRDUPOIS.) It is identical with the pound of apothecary's weight, and the ounce and grain of these two weights are also correspondingly the same. The pennyweight subdivision of troy weight, determining the weight of the silver penny, was established in 1266, as equal to the weight of 32 grains of wheat taken from the middle of the ear. As the kings of later times found it expedient to reduce the value of the penny, this reduction was accompanied by a proportional diminution in the number of grains of which it was composed. A troy weight was established in 1618, the pound of which weighed 1·321 pound troy. This is now abolished by law.

TRUCE OF GOD (Lat. *treuga Dei* or *trewa Dei*, from Ger. *Treue*, faith), an institution of the middle ages, designed to mitigate the violence of private war by prohibiting hostilities from Thursday evening to Sunday evening of each week, also during the entire season of Advent and Lent, and on certain festival days. The days of the week selected were supposed to be rendered holy by the death and resurrection of Christ. It was introduced after the great famine of 1028–'30, by the bishops of Aquitaine, who proclaimed a universal peace; as it was found impossible to enforce this, they were obliged to limit it to certain days, and thus arose the truce of God in its peculiar sense. The regulation soon spread over all France. In 1041 the Aquitanian bishops ordered that no private feuds should be prosecuted from sunset on Wednesday to sunrise on Monday following. This was extended by the council of Clermont to the time from Advent to Epiphany, from Lent to eight days after Pentecost (Whitsuntide), and afterward to the feasts of the Virgin, of John the Baptist, of the apostles Peter and Paul, and of All Saints, and the eves of those days. Calixtus II., at the council of Rheims in 1119, renewed the truce of God, commanding war to cease on the above mentioned times throughout Christendom; all violators were to be excommunicated, and, unless satisfaction were given either by themselves or by their children, were to be denied a Christian burial. When the states of Europe began to assume a more consolidated form, and violations of peace and order came under the control of the civil authority, the truce of God disappeared.

TRUFFLES, underground fungi, used as food; those of commerce belonging to the genus *tuber*, while others which bear the name are of related but different genera. The early English writers called them "trubbes," both names being derived through the Italian from the Latin *terræ tuber*. They are somewhat oblong or globose, varying from two ounces to several pounds in weight, according to species and locality; there are white kinds, but generally the surface is blackish or brownish, and roughened with warty protuberances. When cut open they present a variously marbled appearance, and have no resemblance to the generally known forms of fungi; the hymenium, or reproductive portion, is found in the veins which traverse the mass in all directions; in these are found minute sacs, each containing several spores, the surface of which is covered with spines or is honeycombed. But little is known about their early development, and their mycelium, or vegetative portion; when mature, they are quite free from attachment to any other body. Truffles are generally found in calcareous soils, and always in woods, of oak or beech; hence it has been inferred that at some stage of their existence they are parasitic upon the roots of trees; they are found in many parts of England, more abundantly on the continent, and in Africa. The existence of truffles in the United States is very doubtful; the occasional announcement of their discovery is due to the finding of the Indian bread. (See TUCKAHOE.) In England truffles are hunted by a particular breed of dogs, which are trained by hiding a truffle and teaching them that their food depends upon finding it by the scent; the dogs become so expert that they rarely make a mispoint; when the truffle is dug up, the dog is rewarded with a bit of food. On the continent a similar service is performed by sows. The attempts to cultivate the truffle have not been successful, as the mycelium or spawn, the vegetative portion of the plant, which allows mushrooms to be cultivated so readily, has not yet been obtained. They have been produced by sprinkling the earth with water in which the parings of truffles had been steeped; and in some parts of France a piece of calcareous soil, sown with acorns, has yielded truffles as soon as the saplings attained a few years' growth. The English truffles are *tuber æstivum;* the more highly prized French are *T. melanosporum*, and the Piedmontese, which bring the highest price of all, *T. magnatum;* several others are known which are not found in commerce. In Algiers a truffle of another genus



French Truffle (Tuber melanosporum).

(*terfezia*), and of fair quality, is remarkably abundant, and several have been found in Australia. Truffles have an odor and flavor peculiarly their own, and though sometimes cooked by themselves, they are most generally used for communicating their flavor to meats. The truffles used in this country are imported in sealed tin cans.—The production of truffles in France in 1874 amounted to 1,588,100 kilogrammes (one fourth in the department of Vaucluse), valued at 15,588,100 francs.

TRUJILLO, or Truxillo (anc. *Turris Julia*), a town of Spain, in the province of Cáceres, on the Tozo, a small tributary of the Tagus, 130 m. S. W. of Madrid; pop. about 6,000. It consists of three parts, the citadel, old town, and city, which stand respectively on the summit and slope and at the foot of a hill. The whole place has the appearance of decay, and the upper and more ancient part is now used as a burying ground, the inhabitants having abandoned it. The fortress dates from Roman times. In the lower town there is an extensive square, on which is the mansion of the family of Pizarro, the front being ornamented with numerous bass reliefs representing the conquest of Peru. Roman antiquities have been found here.

TRUJILLO, or Truxillo, a town of Peru, capital of the department of Libertad, 1½ m. from the sea, in the valley of Chimu, 310 m. N. N. W. of Lima; lat. 8° 7′ S., lon. 79° 9′ W.; pop. about 8,000. It is on the side of a mountain, and is surrounded by a mud wall flanked with bastions. It has a cathedral, several churches, a college, a hospital, and a theatre. Rice and spice are exported from Huanchaco, its port, about 8 m. N. W. Trujillo was founded by Pizarro. It has ancient Peruvian remains.

TRUMBULL, a N. E. county of Ohio, bordering on Pennsylvania, watered by Grand and Mahoning rivers; area, 625 sq. m.; pop. in 1870, 38,659. The surface is undulating and well timbered, and the soil fertile and adapted to dairy farming. Pymatuning swamp occupies part of the county. It is intersected by the Atlantic and Great Western railroad and branches, and by the Pennsylvania and Ohio canal. The chief productions in 1870 were 113,476 bushels of wheat, 16,229 of rye, 383,662 of Indian corn, 433,407 of oats, 156,912 of potatoes, 36,194 of flax seed, 213,572 lbs. of wool, 140,723 of maple sugar, 4,651,796 of flax, 1,162,581 of butter, 1,368,595 of cheese, and 59,481 tons of hay. There were 8,067 horses, 19,811 milch cows, 14,297 other cattle, 47,168 sheep, and 7,580 swine; 1 manufactory of bagging, 22 of carriages and wagons, 20 of cheese, 11 of cooperage, 5 of dressed flax, 7 of furniture, 16 of iron, 4 of machinery, 1 of linseed oil, 13 flour mills, 6 tanneries, 4 currying establishments, 3 breweries, 8 planing mills, and 30 saw mills. Capital, Warren.

TRUMBULL, Benjamin, an American clergyman, born in Hebron, Conn., Dec. 19, 1735, died in North Haven, Conn., Feb. 2, 1820. He graduated at Yale college in 1759, and in 1760 became pastor of the Congregational church at North Haven. He served in the revolution both as a chaplain and a soldier. He published "A Plea in Vindication of the Connecticut Title to the contested [Western] Lands" (anonymous, 1776); "Twelve Discourses on the Divine Origin of the Scriptures" (12mo, 1790); a "Complete History of Connecticut, 1630–1764" (2 vols. 8vo, 1797 and 1818); and a "History of the United States" (vol. i., 1810, unfinished).

TRUMBULL, James Hammond, an American philologist, born in Stonington, Conn., Dec. 20, 1821. He entered Yale college in 1838. He was assistant secretary of the state of Connecticut, 1847–'52 and 1858–'61, and secretary from 1861 to 1865. Since 1863 he has been superintendent of the Watkinson library of Hartford and president of the Connecticut historical society. He was one of the original members of the American philological association, and was its president for the year 1874–'5. In 1873 he was appointed lecturer on the Indian languages of North America in Yale college. He has published "Colonial Records of Connecticut, 1636–'89" (3 vols. 8vo, Hartford, 1850–'59); "Roger Williams's Key to the Indian Language" (1866); "The Composition of Indian Geographical Names" (1870); "The Best Method of Studying the American Languages," and "Some Mistaken Notions of Algonkin Grammar" (1871); "Historical Notes on the Constitutions of Connecticut," "Notes on Forty Algonkin Versions of the Lord's Prayer," and a reprint of Pierson's "Some Helps for the Indians" (1873); and several other historical and philological papers.

TRUMBULL, John, an American poet, born in Watertown, Conn., April 24, 1750, died in Detroit, Mich., May 12, 1831. He graduated at Yale College in 1767, and became a tutor in 1771. In 1773 he was admitted to the bar, and in 1781 he removed to Hartford. He was a member of the state legislature, and from 1801 to 1819 a judge of the superior court. In 1825 he removed to Detroit. His best known work is "McFingal," a revolutionary satire (canto i., 1775; complete in 4 cantos, 1782), of which more than 30 unauthorized editions were sold before 1820 (latest ed., with notes by B. J. Lossing, New York, 1864). He also published "The Progress of Dulness," a satire on the prevailing modes of education (3 parts, 1772–'3); "Elegy on the Times" (1774); and with Timothy Dwight 40 papers in the manner of the "Spectator." His "Poetical Works" appeared in 1820 (2 vols., Hartford).

TRUMBULL. I. Jonathan, an American revolutionist, born in Lebanon, Conn., Oct. 12, 1710, died there, Aug. 17, 1785. He graduated at Harvard college in 1727, studied theology, and was licensed to preach, but in 1731 took the place of an elder brother, who was lost at sea, in his father's mercantile business. In 1733 he was elected to the general assembly of Connecticut, of which in 1739 he became speaker. He was chosen an assistant in 1740, and was reëlected 22 times. He became afterward judge of the county court, assistant judge of the superior court, and from 1766 to 1769 was chief judge of the superior court. In 1767 and 1768 he was elected deputy governor, and in 1769 governor of the colony, which office he held till 1783, when he resigned. He was one of the first to espouse the popular cause in the troubles preceding the revolution, and in 1765 refused to take the oath required of all officials to support the provisions of the stamp act; and he coöperated with vigor in securing the independence of the colonies. Washington relied on him, says Sparks, "as one of his main pillars of support," and was accustomed to consult him in emergencies. The personification humorously applied to the United States is said to have had its origin in a phrase sometimes used by Washington: "Let us hear what brother Jonathan says."—See I. W. Stuart's "Life of Jonathan Trumbull, sen." (8vo, Boston, 1859). **II. Jonathan,** son of the preceding, born in Lebanon, Conn., March 26, 1740, died there, Aug. 7, 1809. He graduated at Harvard college in 1759, and was for several years a member of the legislature and speaker of the house. At the outbreak of the revolution he was appointed paymaster to the northern department of the army, which post he held till 1780, when he became secretary and first aide-de-camp of Washington, with whom he remained until the close of the war. He was a representative in congress from 1789 to 1795, and presided as speaker during the last four years. In 1795 he was elected United States senator, and in 1796 lieutenant governor of Connecticut. He became governor in 1797, and held the office until his death. **III. John,** an American painter, brother of the preceding, born in Lebanon, Conn., June 6, 1756, died in New York, Nov. 10, 1843. He graduated at Harvard college in 1773, and afterward studied painting in Boston. In the spring of 1775 he joined the first Connecticut regiment as adjutant, and in August became second aide-de-camp to Washington, and soon after major of brigade. In 1776 he was appointed by Gen. Gates adjutant general with the rank of colonel, which office he resigned in the spring of 1777. In 1780 he went to London and became a pupil of Benjamin West, but was arrested soon after, during the excitement occasioned by the execution of Major André, and imprisoned for eight months. He was finally admitted to bail on condition of quitting the kingdom within 30 days, and returned home in January, 1782; but on the conclusion of peace he again went to England and resumed his studies under West. In 1786 he produced his first modern historical picture, the "Battle of Bunker Hill," and soon after his "Death of Montgomery before Quebec," the former of which was engraved by J. G. Müller of Stuttgart, and the latter by F. Clemens of London. His next picture, the "Sortie of the Garrison from Gibraltar," one of the repetitions of which is in the Boston Athenæum, is widely known through Sharp's engraving. In 1789 Trumbull returned to America to procure likenesses of revolutionary officers for his contemplated series of national pictures. He painted several portraits of Washington, one of which belongs to the city of New York. In 1794 he went again to England as secretary to Mr. Jay, the American minister, and in 1796 was appointed fifth commissioner for the execution of the seventh article of Mr. Jay's treaty of 1794. The duties of this office occupied him till 1804, when he returned to the United States. From 1808 to 1815 he resided in England, painting with indifferent success; and from 1817 to 1824 he was employed in executing for congress four pictures to fill compartments in the rotunda of the capitol, each 18 by 12 ft. For these works, which represent respectively the "Declaration of Independence," the "Surrender of Burgoyne," the "Surrender of Cornwallis," and the "Resignation of Washington at Annapolis," he received $32,000. Subsequently for many years he was engaged in finishing former sketches and in painting copies of his national pictures on a uniform scale of 9 by 6 ft. Many of these, together with portraits and several copies of the old masters, 54 pictures in all, he finally gave to Yale college in consideration of a life annuity of $1,000. The collection was at first deposited in the "Trumbull gallery," a building erected especially for it, but in 1867 it was transferred to the new art building. Col. Trumbull passed the latter part of his life in New York, and was president of the American academy of fine arts from its foundation in 1816 until the formation of the national academy of design in 1825.

TRUMPET, a musical wind instrument of brass or other metal, which under one form or another has been known in all ages and among all races having any claim to civilization. The trumpet, so called in modern use, is generally understood as a tube 8 ft. in length, expanding at the end whence the sound issues into a bell-like shape, and doubled up in a parabolic form. It is played through a mouthpiece, and has a natural compass from G below the staff to E above. Trumpets with pistons and cylinders have the advantage of being able to give all the intervals of the chromatic scale.

TRUMPETER, in ornithology. See Agami.

TRUMPET FISH. See Pipe Fish.

TRUMPET FLOWER, a popular name especially for *tecoma radicans*, used with a prefix for other related plants. The genus *tecoma* (from the Mexican name), separated from *Bignonia* on account of a structural difference in the pods, consists of about 50 species, mostly trees and natives of tropical America. The trumpet flower, *T. radicans*, is a woody vine, climbing to a great height by abundant rootlets produced along the stem; the pinnate leaves have 5 to 11 ovate, toothed, pointed leaflets; the flowers, in midsummer or later, are in corymbs; the corolla is tubular-funnel-shaped, 2 to 3 in. long, with five somewhat irregular lobes, within which the four stamens are included; the fruit is a two-celled pod, containing numerous winged seeds. This, which is often called trumpet creeper, is found from Pennsylvania and Illinois southward, and is very common in cultivation, it being vigorous and perfectly hardy, soon covering a large space, and reaching to the height of 60 ft.; it blooms in July and August, when flowers are scarce, and the abundance of its orange and scarlet bloom makes it very showy. It is a useful vine to drape a tree that is not in itself pleasing, and to cover the sides of brick or stone buildings; its faults are a tendency to become naked below, which may be remedied by cutting back, and an abundant production of suckers; it should not be planted near borders, as its roots extend a long distance.—*Bignonia capreolata* is a closely related climber, with a more southern range; its leaves consist of but two leaflets and a terminal tendril; its flowers, similar to those of the preceding, are orange; this is known in the southern states as cross-vine, as the wood cut transversely shows a cross. The great-flowered trumpet flower (*tecoma grandiflora*), from China and Japan, in its garden varieties, is a very showy climber; it does not reach very high, and has narrower leaflets than our native species and much larger flowers, which are bell-shaped and 3 in. across; in some varieties they are very dark-colored; it is scarcely hardy north of New York city.—Some species are cultivated in greenhouses, the most frequent being *T. Capensis*, with curved orange flowers, and *T. jasminoides*, from Australia, with bright green leaves, and white flowers which are purplish on the throat. The related *Bignonia venusta*, from Brazil, with crimson flowers, is a gorgeous climber for a warm greenhouse. A very neat non-climbing shrub is *tecoma stans*, of southern Florida and northern Mexico; it is about 4 ft. high, with large clusters of lemon-yellow flowers; it is hardy at Washington.

Trumpet Flower (Tecoma radicans).

TRUNK FISH, the name of the plectognathous fishes of the genus *ostracion* (Linn.), derived from the bony case in which their soft parts are enclosed; they are also called coffer fishes. The head is prolonged into a snout, at the end of which is the mouth, with fleshy lips, and armed with a series of distinct teeth, 10 or 12 in each jaw, received into sockets, somewhat like the human incisors; body covered by bony plates, large, quadrangular or hexagonal, encasing the animal in an inflexible bony armor; tail enclosed in a bony tube, this and the pectoral fins being the only movable parts; even the vertebræ are usually immovable; eyes large and prominent; dorsal single, far back, small, and entirely soft; pelvic bones and ventrals absent; body three- or four-sided, with linear branchial openings, bordered by a fleshy edge within which are the gill covers. They have very little flesh, and some are believed to be poisonous; the stomach is membranous and very large; the liver is also large, often yielding a considerable quantity of oil; some are armed with spines on the head and body; they are generally small, and found in the tropics. There are a few species on the coast of the United States, arranged by De Kay in his genus *lactophrys*, having a triangular body, with strong spines, directed backward, in front of the anal fin, and the orbits usually spinous. Yale's trunk fish (*O.* [*L.*] *Yalei*, Storer), on the coast of Massachusetts and New York, is 14 in. long, with two abdominal spines. There are also species in the East Indies.

Yale's Trunk Fish (Ostracion Yalei).

TRURO, the capital of Colchester co., Nova Scotia, at the head of Cobequid bay, and on the Intercolonial railway at the junction of the Pictou branch, 67 m. by rail N. N. E. of Halifax; pop. in 1871, 3,998. It is one of the handsomest places in the province, and contains, besides the county buildings, several churches, a branch bank, and the provincial normal and model schools. There are manufactories of engines, iron castings, axles, machinery, boots and shoes, lasts and pegs, hats, leather, wooden ware, and woollens.

TRUSS, a contrivance for preventing the reappearance of a hernial tumor after its reduction. The general form of the truss is a flat steel spring covered with soft leather or oiled silk, and having its ends approximating to within a few inches of each other; attached to one end is a small round or oval pad, stuffed with cotton or wool, and having for its basis a small iron plate; the other end of the spring has either a larger and flat pad, or a strap connected with it. The smaller pad is placed over the ring or point where the hernial tumor has protruded (see HERNIA), and the spring passes over the hip, and either exerts its pressure by means of the large counter pad on the back, or is by means of a strap passing over the opposite hip connected with the pad by a buckle or eyelet and button on the back of the pad. Sometimes, where it is necessary to adjust it with great care, another strap passing over the inner surface of the thigh connects with the spring on the back. Where, as is sometimes the case, there is a double hernia, this spring is made sufficiently long to clasp over both hips, and has a pad at each end. In this case there should be a pad attached to the middle of the spring to exert gentle pressure on the spine, and thus keep the truss more perfectly in position. There are numerous patterns of trusses, varying considerably in form, but they may all be reduced to three classes: those with a flat pad, intended to press upon the whole surface of the ring or place through which the intestine protrudes; the oval or egg-shaped pad, which presses directly into the ring, and thus prevents the escape of the intestine; and the semicircular pad, which acts by supporting the intestine from above and pressing it away from the point of rupture. The truss, though preventing the recurrence of the hernial tumor when properly adjusted, seldom effects a radical cure. This has been attempted by purposely so adjusting it as to cause it to produce some inflammation and adhesion of the serous surface around the ring so as to effect complete occlusion of it; but it should never be done except under the direction of a skilful physician, as it is attended with danger.

TRUSTEE PROCESS, a process in certain states for reaching the goods or credits of a debtor in the hands of another who holds them for or is indebted to him. The proceeding for the purpose is by suit collateral to the suit against the debtor, in which the person proceeded against will be charged as trustee of the debtor, and adjudged to pay or account in satisfaction of the principal claim. The alleged trustee is examined on oath, and whatever belonging to the debtor is found in his hands is attached from the time the process is served upon him. The proceeding is purely statutory. In some states the corresponding proceeding is called a proceeding in garnishment, and the trustee is designated a garnishee. In these proceedings the trustee cannot be compelled to do more than he was bound to do by his contract or arrangement with the debtor.

TRUSTS. It is quite certain that trusts, which have now such immense importance in the law and the disposition of property in England and in the United States, originated in fraud. The feudal law of tenures embarrassed owners of property in their disposal of it, and the statutes of mortmain obstructed the appropriation at the pleasure of the owner still more; and to evade these rules of law, trusts (or the granting of property in trust) were invented. As the common law took no cognizance of trusts, they came before a court of equity. And if we remember that the chancellor was in early times usually a priest, and that the statutes of mortmain, which trusts were invented to evade, restricted or prohibited the granting of property to religious communities, we can understand why the court of equity took them under its protection. It did this by summoning the trustee before it, and compelling him "to do what justice and equity required." Hence Sir Robert Atkins, in the reign of Charles II., said: "A trust had for its parents fraud and fear, and for its nurse a court of conscience." The way in which these laws were successfully evaded by trusts was this. If property is given to A. B., with all the forms of law, and in the same manner as if it were to be absolutely his own, but in fact for the use and benefit of C. D., the common law knows no one but A. B.; all the title is in him, and the estate in him is protected against all forfeitures but those which attach to him. But C. D. has all the benefit and advantage of the property. Hence if C. D. were a traitor, who would have forfeited the estate had it been his in law, or a religious body which could not take the estate by law, A. B. still might hold it for the benefit of C. D. In this way fraud and fear were the parents of trusts. But as the law knew no estate or title but that of A. B., if he chose to be dishonest, and to refuse all benefit of the trust to C. D., there was no remedy at law, and the trust would have been defeated. Then the court of equity came in, and, by compelling A. B. to perform the trust he had undertaken, became the nurse of this child of fraud. Now, however, trusts are employed in a vast number of cases, most honestly and beneficially, wherever it is desired to give any person the benefit and use of property, but to keep from him all power of forfeiting or alienating it. The greatest number of modern trusts are created either by will or by transfer *inter vivos* to protect the estates of women from the control or the creditors of their husbands, or to carry down property to a series of holders, in some other way than that which would be provided by the laws of inheritance or distribution. To all trusts there are therefore two parties. One of these holds the legal title to the estate, and he is called trustee; the other has the actual benefit of the trust, and is called, by a Norman French phrase, the *cestuy que trust*. As the trustee has all the title which a court of law can recognize, he is said to have the legal estate; and as the *cestuy que trust* has an interest which only a court of equity can recognize and protect, he is said to have an equitable estate. At present, when the courts of law and the rules of law are coming nearer to the courts and the rules of equity, the antagonism between these has passed away, and the distinction become much less important. There may be any number of trustees and any number of *cestuy que trusts* in any trust. If the trustee holds the property for the benefit of the *cestuy que trust* without any particular restrictions, directions, or provisions, it is called a simple trust; and then the nature and operation of the trust are determined by legal or equitable construction. But if the purposes of the trust, and the manner in which and the means by which these purposes shall be accomplished, are specifically pointed out and defined, it is then a special trust, and these special directions must be accurately complied with. Hence a trust may be merely ministerial; and it is so called when the trustee has no other duty than to collect and pay over the proceeds of property. Or it may be a discretionary trust, and is so when the general purpose only is declared, and the manner in which this purpose shall be accomplished is left to the discretion of the trustee. So a trust may have a power annexed; as when a trustee of lands has the power of leasing, or even of selling and converting them into personal property. And indeed any lawful powers may be given to a trustee. There are also private trustees and public trustees. The former hold property for one or more individuals, who are distinctly pointed out, personally or by description. Public trustees are those who hold property for the benefit of the whole public, or for a certain large part of it, as a county, town, or parish. They are regarded by the law as in many respects official persons, with official rights and responsibilities.—The subject matter of a trust may be any property of a valuable nature, and many things also which the common law does not recognize as disposable or assignable property; as choses in action and probabilities of every description, or mere authorities which may be or become valuable. Even if the property be in another state or country, so that the process of the court could not reach it, yet a court of equity will interfere in any case of trust, however distant or inaccessible the property may be, provided the principal defendants are actually served with process, and adequate relief may be given by a decree *in personam.*—As to the capacity of creating a trust, it may be said that any person who has the power of making a valid disposition of any property, by will or grant, has also the power of attaching to his disposition of the property such limitations or directions as shall create a trust. As a general rule, any person may be a trustee, even if he be incapacitated by law from transacting business on his own account. Thus infants, idiots, lunatics, married women, or other persons *non sui juris*, may become trustees. The reason is, that the trust is created for the benefit of the *cestuy que trust*, and not of the trustee; and if the trustee cannot take the legal estate, there will be nothing to support the equitable estate, and the trust will fail. So, too, it is established doctrine that a trust once created shall never fail on account of the death of a trustee, or his refusal to accept the trust. All difficulties of this kind are avoided by the power of the proper court (usually the court of equity) to remove a trustee and supply his place, or fill the place of a trustee when vacant by his death or refusal. It is very common for a will or deed creating a trust to prescribe in what way and by what person or tribunal this power may be exercised; and provisions to this effect would doubtless be regarded when they did not contravene the general principles of the law, or the statutory provisions in behalf of trusts and trustees. Any person in possession of property, real or personal, by legal title and of his own right, may, by a proper declaration of trust, convert himself into a trustee, and then his legal title will remain undisturbed, but subjected to the equitable interest.—Any person may become a *cestuy que trust* of property, to the extent of his legal capacity of holding the same. Nor is it necessary to the creation of a trust estate that the *cestuy que trust* should be named, or even that he should be in being when the trust is created. Thus money may be bequeathed or given to a trustee for any children that a certain person may have living at his death, and to accumulate until the death of that person. The assent of the *cestuy que trust*, if he is capable of giving one, is, strictly speaking, necessary; but it will be presumed where the trust is beneficial to him. Unincorporated societies and institutions may take the benefit of a trust, as well as natural persons or corporations.—Trusts and uses (see Uses) were originally created and declared principally, if not exclusively, by parol; but this was because they were then intended to evade the law. Now, it is uncertain whether trusts of real estate can be created except in writing, and for some purposes by deed. In most of the United States, the provisions of the English statute of frauds, requiring trusts to be in writing, have been reënacted. But in England courts of equity have given a very liberal construction to these provisions, and a similar construction might be expected here. Where a trust is created, if at all, by a writing, especially if that writing be a will, any direct fiduciary expressions, indicative of a purpose that the donee of the property is to take it, in whole or in part, for the benefit, use, advantage, or support of another, will be held sufficient to create a trust. But such words or directions must be imperative on the donee; if they, by fair construction, only give him a power or permission, or even express a desire which is not obligatory on him, they do not create a trust. If the trust is distinctly and positively created, although no *cestuy que trust* is designated, the courts will enforce the trust.

If the donee may at his own discretion or pleasure execute the alleged trust or not, it is not a trust; but it is a valid trust if he must execute the trust, although the manner of doing it is entirely at his discretion. So, too, there may be what are called "resulting" or "presumptive trusts," which are expressed nowhere, but are implied or presumed from the assumed intention of the parties, or arise from the nature of the transaction; and the statute of frauds expressly excepts these trusts from the requirement of writing.—A trustee is always at liberty to decline a trust, but he cannot take the property without the trust. The best and usually the only evidence of an acceptance of the trust is some action by the trustee under it. The same person may stand in different relations; thus he may be appointed executor and also trustee; and he may give separate bonds with different sureties, as executor and as trustee. In such cases it is sometimes difficult to say where the duty and responsibility of executor end and those of trustee begin. The general rule is this: If the executor has specifically set apart a portion of the estate to the purpose of the trust, he will be considered as to that portion as having discharged his duty as executor and entered upon his duty as trustee.—An important doctrine of the law of trusts, familiar to English lawyers and frequently applied in English courts, is known by the name of the *cy-pres* doctrine. This phrase means literally "near to it;" and this doctrine is applied when a trust is certainly created, and it is impossible to execute it precisely as the donor prescribed, and then a court of equity, from its desire to sustain the trust, will direct an exercise of it as near as possible to the original intention of the donor. By far the most frequent occasion for its application arises from the change of circumstances in ancient trusts; as, for example, where there is an endowment for a school limited to pupils of a certain description, and there are not now any pupils of that description. But that necessity cannot exist so frequently or with so much force in the United States as in England. As an undefined judicial power, it is open to abuse, and can scarcely be said to be recognized in the United States.—Trustees are held, both in England and in this country, to a somewhat strict accountability. A trustee is bound not only to guard against loss or damage to the trust property, but to see that it is made reasonably productive. If he suffers it to lie idle unreasonably, when safe investments can be made, he will be charged with interest, and in some cases, as when he is guilty of gross delinquency, or if he mingles the property with his own for his own benefit in trade or otherwise, he will be charged with compound interest. He may not himself buy property which he sells as trustee, nor sell his own property and buy it as trustee; and this rule is applied not only to all trustees, but to agents generally.—An important difference between private and public trustees should be mentioned. Private trustees are responsible on the contracts they make as trustees, unless they guard against this by express reservation; and merely calling themselves trustees, or even saying they act as trustees, is not, generally speaking, sufficient. Thus an executor, signing a common promissory note as executor, is still liable on it personally, although the estate be insolvent. But public trustees, or persons acting in a known official capacity, are not personally liable on the contracts they make for the state or government, unless they make themselves so expressly or by a reasonable implication, or have in their hands funds for the purpose of the contracts. It is, of course, always in the power of one who deals with a public trustee or agent to ask of him his own personal liability; and it is always in the power of that trustee to give it or withhold it.

TRUXILLO. See Trujillo.

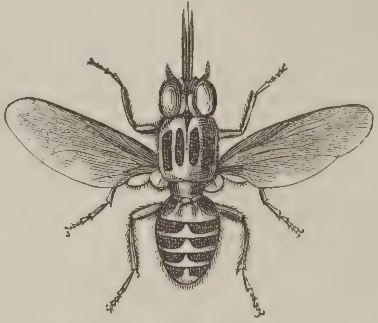
TRUXTUN, Thomas, an American naval officer, born on Long Island, Feb. 15, 1755, died in Philadelphia, May 5, 1822. During the revolution he served in privateers as lieutenant and captain, and made valuable captures. In 1795 he received a commission as captain in the navy. On Feb. 9, 1799, in the frigate Constellation, 38 guns, off the island of Nevis, he captured the French frigate L'Insurgente, 40 guns, which was much cut up, and lost 29 men killed and 41 wounded. The Constellation sustained but little injury, and had one man killed and three wounded. On Feb. 1, 1800, the Constellation engaged off Guadeloupe the French frigate La Vengeance of 54 guns, which escaped into Curaçoa dismasted and sinking, with a loss of 50 killed and 110 wounded. The loss of the Constellation was 14 killed and 25 wounded. Her mainmast went by the board at the close of the action, which prevented her from pursuing. For this action congress awarded Truxtun a gold medal. In 1802 a squadron was fitted out against Tripoli, and Truxtun having declined the command because he was refused a captain for his flag ship, his declination was construed into a resignation, and his name was struck from the navy list. He retired to Philadelphia, where in 1816-'19 he was high sheriff. He published "Remarks relating to Latitude and Longitude and Variation of the Compass" (1794), and a volume of extracts on naval tactics (1806).

TSARSKOE SELO. See Tzarskoye Selo.

TSCHIRNHAUSEN, Ehrenfried Walter von, count, a German mathematician, born at Kislingswald, near Görlitz, April 10, 1651, died there, Oct. 10, 1708. He studied at Leyden, in 1672 volunteered against France, and afterward visited England, France, and Italy. After his return he constructed optical instruments, and established glass factories and a mill for the polishing of burning glasses, one of which weighed 160 lbs. and was 33 in. in diameter. He also constructed a burning mirror of highly polished copper, producing effects similar to those of the burning glass. He discovered a method from which the manufacture of porcelain in Saxony took its rise, and investigated the properties of the curves which go under his name. He published *Medicina Corporis* (Amsterdam, 1686) and *Medicina Mentis* (1687), afterward combined in several editions, and *Anleitung zu nützlichen Wissenschaften, absonderlich zu der Mathesis und Physik* (Leipsic, 1700; 3d ed., 1712).

TSCHUDI. I. Ægidius (Gilles), a Swiss historian, born in Glarus in 1505, died there, Feb. 28, 1572. He served in the French army from 1536 to 1544, held several important offices in his canton both before and afterward, and in 1559 went as Swiss envoy to the imperial court of Ferdinand I. at Augsburg. He was banished in 1562 for inducing the Catholic delegates to attend the council of Trent, but was recalled in 1564 to settle the conflict between the see and the city of St. Gall. He wrote many works, of which the best known is his *Chronicon Helveticum* (in German), embracing the history of Switzerland from 1000 to 1470 (2 vols., Basel, 1734–'6). **II. Johann Jakob von,** a Swiss naturalist, a descendant of the preceding and grandson of a historian of the same name, born in Glarus, July 25, 1818. He completed his studies in Paris, and explored Peru from 1838 to 1843, and Brazil and other South American states in 1857–'9, and subsequent to his appointment as Swiss minister to Brazil in 1860. In 1866 he became minister at Vienna. His works include *Peru: Reiseskizzen aus den Jahren* 1838–'42 (2 vols., St. Gall, 1846; translated into English in 1847 by T. Ross); *Untersuchungen über die Fauna Peruana* (St. Gall, 1844–'7); *Die Ketschuasprache* (2 vols., Vienna, 1853), with a Peruvian grammar and dictionary; *Reise durch die Andes von Südamerika* (Gotha, 1860); *Die brasilische Provinz Minas-Geraes* (Gotha, 1863); and *Reisen durch Südamerika* (5 vols., Leipsic, 1866–'9). He has also edited, in conjunction with Don Mariano Eduardo de Rivera, the *Antigüedades Peruanas* (Vienna, 1851; translated by the Rev. F. L. Hawks, 8vo, New York, 1854). **III. Friedrich von,** a naturalist, brother of the preceding, born in 1820. He became president of the council of education of the canton and great councillor of the city of St. Gall, and wrote a popular manual of agriculture and other works. His *Thierleben der Alpenwelt* (Leipsic, 1852; 9th ed., 1872) has been translated into several languages.

TSETSE, the native name of a proboscidian dipterous insect of the genus *glossina* (Wiedemann), peculiar to Africa, and especially to the tropical portions. This genus comes near *stomoxys* (Fabr.), and resembles in appearance and habits the gadfly called in Scotland cleg (*hæmatopota pluvialis*, Meig.). The best known species, *G. morsitans* (Westw.), is 5 lines long and 8½ in expanse of wings, a little larger than the house fly; the head is dirty buff, and the eyes are large; thorax chestnut red, with four longitudinal black bars; abdomen dirty buff, with black bristles above, the first segment with a round black spot at each side, and the four following with a broad dark brown band interrupted in the middle; the wings are considerably longer than the body. The blood-sucking apparatus consists of a long horny proboscis, containing a compound bristle or two needle-like piercers, communicating with a poison bulb at the base, and supported on each side by two feathery palpi. It is very active and difficult to catch, except in the cool of the morning and evening, when it is sluggish; it has a loud and peculiar buzz, which does not terrify cattle like that of the gadflies. This scourge of the African wilderness has no sting in the tail, and deposits no eggs on or under the skin of animals, but introduces its poison into the blood by the proboscis while sucking. The puncture of the tsetse is almost certain death to the ox, horse, sheep, and dog, but is harmless to man, the mule, ass, goat, pig, wild animals, and even calves while sucking; in man it causes a slight itching, like that produced by the bite of the mosquito or flea. It produces no immediate effect in the ox or horse, but in a few days there appears an exudation for half an inch around the punctures, the eyes and nose begin to run, the skin quivers as if from cold, and swellings occur under the jaw; the animal may continue to graze, but by degrees grows thin and weak; this state may continue for months, until purging comes on, and death ensues from exhaustion. The better the condition of the animal bitten, the more speedy often will the death be, accompanied by symptoms of staggering and blindness; sudden changes of temperature hasten the progress of the disease, which goes on to certain death. They occasionally attack a horse like a swarm of bees, alighting on him by hundreds, sometimes causing death in a week. After death the subcutaneous areolar tissue is found to be injected with air, and the fat is oily and greenish yellow; the heart and muscles are very soft and flabby, the gall bladder distended with bile, the blood much reduced in quantity, with signs of disease in the lungs and liver. No remedy is known; the natives



Tsetse (Glossina morsitans), enlarged.

pretend to have roots which, pounded and sprinkled on the hair, prevent the bite, but their inability to keep cattle proves their inefficacy; the droppings of animals mixed with human milk and drugs, and smeared on the hide, often prove a temporary safeguard; an animal slightly bitten and escaping death will fall a victim to the next severe bite. With the destruction of the game, this insect, deprived of its food, may become extinct; and until it does, whole districts are rendered unable to keep cattle, horses, sheep, or dogs. It is found chiefly in the bush or among reeds, and rarely in the open country; it is confined to limited regions, which it never leaves, so that cattle may graze in quiet on one side of a river while the opposite bank swarms with tsetse. When obliged to pass through a country infested by them, the natives select a moonlight winter night, when they are torpid from cold. The flesh of animals bitten by the tsetse is not unwholesome, if they are killed before emaciation and weakness supervene. C. J. Andersson and Dr. Livingstone give extended accounts of the ravages of this insect.

TSURUGA, a city and seaport of Japan, in the province of Echizen, at the head of a bay of the same name on the W. coast of the main island, about 200 m. W. of Tokio; pop. about 20,000. It is almost the only good port on the W. side of the island, and attracts most of the junk and steamer trade. Its harbor is deep, spacious, and well protected. A canal connecting the bay with Lake Biwa, and thence through the Yodo river with the Inland sea, has long been projected by the government, and a railroad to Kioto and Osaka is now in progress (1876). The district around Tsuruga, which contains several large towns, is noted for its rice, silk, tea, paper, lacquer, and copper. Granite is quarried near the city, and lime is made in large quantities from marble.

TUAM, a town of Connaught, Ireland, in the county and 19 m. N. N. E. of the city of Galway, on both sides of the Harrow; pop. in 1871, 4,223. It contains both a Protestant and a Roman Catholic cathedral, the latter one of the finest churches in Ireland, the Roman Catholic college of St. Jarlath, several public schools, a monastery, a nunnery, and a workhouse. The manufactures are chiefly coarse linens. Tuam is a place of great antiquity, and had a cathedral founded by St. Jarlath in the 6th century. It is the see of a Roman Catholic archbishop, and was an archiepiscopal see of the established church till 1839, when it was reduced to a bishopric, with Killala and Achonry, suffragan to Armagh.

TUARIKS, or **Tuaregs,** a people supposed to be of the Berber race, occupying the desert of Sahara westward from Fezzan to the Atlantic. According to their own traditions, they came originally from Canaan. They are Caucasian in feature, and, though of dark complexion, have straight hair, and bear no resemblance to any of the negro races. They are bold, warlike, and predatory, and live chiefly on booty and tribute exacted from the caravans crossing their country. They are very zealous Mohammedans, and are governed by independent chiefs. They are divided into several tribes, the principal being the Azkar Tuariks. The Tibboos, who occupy the portion of the desert between Fezzan and Egypt, are considered a branch of the same family. The total number of the Tuariks is estimated at somewhat less than 200,000.

TUBERCLE. See CONSUMPTION.

TUBERCULOUS MENINGITIS. See BRAIN, DISEASES OF THE, vol. iii., p. 201.

TUBEROSE, a plant of the amaryllis family, *polianthes tuberosa*, cultivated for its fragrant flowers. The generic name, from the supposition that it refers to many flowers, is frequently written *polyanthes*, but it was given for the reason that it is especially a flower of cities (Gr. πόλις, a city, and ἄνθος, a flower). The common name is from the specific *tuberosa*, it having been called by the old French gardeners *plante tubereuse;* this is commonly corrupted into tube rose, and the plant spoken of as if it were a variety of the rose. It has a solid, pear-shaped tuber, from the base of which proceed roots, and from the apex long, linear, channelled leaves, and late in summer a stem 2 to 3 ft. high, the upper part of which is crowded with short-pedicelled flowers, and the lower part bears a few short leaves; the flowers consist of a funnel-shaped, slightly curved tube, with six nearly equal, spreading lobes, often tinged with rose without, creamy white within, with a powerful and, to some, oppressive fragrance; both single and double forms are cultivated. A few years ago an accidental variety appeared in the grounds of Mr. John Henderson, Flushing, N. Y., which has been called "the Pearl," and is of especial value in having the stem only about half the usual height, while bearing quite as many flowers. In a commercial view the tuberose is one of the most important of florists' plants; it is but a few years since the bulbs were all imported, some from Holland, but the finest from Italy; after a while it was found that they would grow as well in New Jersey as in Holland,

Double Tuberose (Polianthes tuberosa).

while those raised in Georgia and Florida are much larger and finer than any that can be produced abroad, and their culture is rapidly extending. The old tubers produce around the base numerous offsets, which serve for propagation; these are cultivated in rows, like onions, for one or two years, according to size, to make flowering bulbs, as they are called in the trade. To insure their flowering, the tubers should be stored where the temperature will not go below 50°, or the undeveloped flower buds may be killed. If the dry tubers are planted in the open ground in northern localities, the flowers are apt to be killed by frost, just as they are opening; to avoid this the bulbs should be put in boxes or pots of earth early in May, and placed in a greenhouse or warm window, where they will start, and then transferred to the open ground, after cold storms are over, in June. Botanists are not agreed as to the native country of the plant, some accrediting it to the East Indies and others to Mexico, but it must be treated like a native of the tropics. The flowers, both from being white and on account of their fragrance, are in great demand for bouquets and floral designs, and florists resort to every means to secure a supply during the winter. For early winter flowers, the plants that have not yet bloomed in the open ground are taken up and put in the greenhouse; and bulbs of the previous year's growth are carefully kept until August, when they are planted under glass. For forcing purposes the dwarf variety mentioned is especially valuable; the forced plants are rarely potted, but set in a bed of earth made upon the greenhouse bench. A tuber or bulb after it has once flowered is valueless.

TÜBINGEN, a town of Würtemberg, in the circle of the Schwarzwald, on the left bank of the Neckar, 18 m. S. W. of Stuttgart; pop. in 1872, 9,313. It has two new suburbs, an old *Stiftskirche* and several other Protestant churches, and a Roman Catholic church. The university, founded in 1477, has been distinguished since the 16th century in Protestant theology and in philosophy, and especially in the present century through the new Tübingen school of theology founded by F. C. Baur. In 1876 it had seven faculties, with more than 80 professors and other teachers, nearly 900 students, and about 40 distinct institutions, including the library in the Hohentübingen palace, with 200,000 volumes and 2,000 manuscripts.

TUCKAHOE, the aboriginal name of a curious subterraneous vegetable production, also called Indian bread and Indian loaf, found from New Jersey southward to the gulf and westward to Arkansas. It is in roundish masses, from the size of a pullet's egg to that of a cocoanut or much larger; its brownish surface resembles that of a loaf of coarse bread, while within it is a homogeneous whitish mass, with an earthy odor, and on drying cracks and becomes hard. It is usually found at planting time, when it is turned up by the plough, and presents no indications of having been attached to the roots of plants, or to a *mycelium*, as are most fungi. Under the supposition that it was a fungus, Clayton, and afterward Schweinitz, placed it with the puff-balls as *lycoperdon solidum*, and Fries called it *pachyma cocos;* but there is no reason for considering it a fungus, other than its underground manner of growth, and its somewhat distant exterior resemblance to the truffle (see TRUFFLE); on account of these it has been mistaken for the truffle. From the entire absence not only of reproductive organs, but of all cellular structure, and the lack of all knowledge of it in an early stage of its development, the tuckahoe has long been a puzzle to naturalists. About 30 years ago the late Prof. John Torrey made a chemical examination of it, and, while he was unable to detect by chemical tests the presence of starch, which the microscope had also failed to show, ascertained that the mass consisted almost entirely of pectin, which in some of its modifications is the jelly of fruits. It has been suggested by Berkeley and others that the tuckahoe is a secondary product, caused by the degeneration of the tissues of the root of some flowering plant, in which a change has occurred similar to that which converts animal tissues into adipocere, and that the cellulose and all other principles are transformed into a body of the pectose group; this is a conjecture only, against the probable truth of which is the fact that no intermediate states have been found, while none, large or small, present any trace of plant structure. The name tuckahoe is said to have been applied by the Indians to several edible roots, and indicates that they used this as food; it is employed in the southern states, boiled in milk, as a nutritious diet in diseases of the bowels, instead of arrowroot, and has been recommended in a medical work as a starchy food, while it contains no starch.

TUCKER, a N. E. county of West Virginia, touching Maryland on the northeast; area, about 400 sq. m.; pop. in 1870, 1,907, of whom 27 were colored. It is drained by Cheat river, a tributary of the Monongahela. The surface is broken and mountainous. The valleys are productive. The chief productions in 1870 were 1,469 bushels of wheat, 1,294 of rye, 27,813 of Indian corn, 14,726 of oats, 1,843 of buckwheat, 2,083 of potatoes, 6,093 lbs. of wool, 26,769 of butter, and 1,498 tons of hay. There were 493 horses, 637 milch cows, 1,084 other cattle, 2,608 sheep, and 1,045 swine. Capital, St. George.

TUCKER, Abraham, an English metaphysician, born in London, Sept. 2, 1705, died at his seat in Surrey, Nov. 20, 1774. He was educated at Oxford. In 1727 he purchased Betchworth castle, with a large estate, near Dorking, and there devoted himself to the study of agriculture. In 1754 he published the letters which had passed between himself and his wife, under the title "A Picture of Artless Love," and in 1755 a pamphlet against strong political feeling, entitled "The Country Gentleman's Advice to his Son on the Subject of Party Clubs." About this time he began his great work, "The Light of Nature Pursued, by Edward Search," four volumes of which were published in 1765; but a part of it had already appeared in 1763 under the title of "Free Will." In reply to a criticism on the work in the "Monthly Review," he wrote "Man in Quest of Himself, by Cuthbert Comment." He became blind in 1771, but continued to work upon his "Light of Nature Pursued," the remaining volumes of which were edited by his daughter, after his death. The best edition is that of Sir Henry Mildmay (7 vols. 8vo, 1805; 4 vols., Cambridge, Mass., 1831; 2 vols., London, 1852).

TUCKER, Josiah, a British clergyman, born at Laugharne, Carmarthenshire, in 1711, died in Gloucester, Nov. 4, 1799. He was educated at Oxford, took orders, and in 1749 became rector of St. Stephen's, Bristol, and in 1758 dean of Gloucester. He published "A Brief Essay upon the Advantages and Disadvantages which respectively attend France and Great Britain with regard to Trade" (1748); "The Case of going to War for the sake of Trade, considered in a new Light" (1763), a pamphlet, translated into French by Turgot; "A Treatise concerning Civil Government" (1781); and "Reflections on the Present Matters in Dispute between Great Britain and Ireland" (1785). At the American revolution he resisted the claims of the colonies, but opposed coercion, as he believed that the possession of colonies was detrimental to the interests of a country. In theology he published an "Apology for the present Church of England," "Letters to Dr. Kippis," "Religious Intolerance no part of the General Plan either of the Mosaic or Christian Dispensation," and "Seventeen Sermons on some of the most important Points of Natural and Revealed Religion."

TUCKER. I. St. George, an American jurist, born in the island of Bermuda, June 29, 1752, died in Nelson co., Va., in November, 1827. He was educated at the college of William and Mary, and studied law, but on the breaking out of the revolutionary war took up arms, and planned and aided in the capture of a large amount of stores in a fortification at Bermuda. In 1778 he married Mrs. Randolph, the mother of John Randolph of Roanoke. At the siege of Yorktown he was present as a lieutenant colonel. After the conclusion of the war he was elected a member of the general court, and was also law professor in William and Mary college. He was one of the commissioners to the convention of 1786 at Annapolis, Md., and recommended the convention of 1787 which framed the federal constitution. In 1803 he was appointed judge of the court of appeals, and in 1813 of the district court of the United States. He published "How far the Common Law of England is the Common Law of the United States;" "Dissertation on Slavery, with a Proposal for its Gradual Abolition in Virginia" (1796; new ed., New York, 1861); a letter on the "Alien and Sedition Laws" (1799); an annotated edition of Blackstone's "Commentaries;" and a volume of poems, including the well known and popular "Days of my Youth." **II. Henry St. George,** an American jurist, son of the preceding, born Jan. 5, 1781, died in Winchester, Va., Aug. 28, 1848. He received a liberal education, studied law, and became president of the court of appeals and professor of law in the university of Virginia. From 1815 to 1819 he was a member of congress. His works include "Lectures on Constitutional Law;" "Commentaries on the Laws of Virginia" (2 vols. 8vo, Winchester, 1836); and "Lectures on Natural Law and Government" (Richmond, 1843). **III. Nathaniel Beverley,** an American lawyer, brother of the preceding, born at Matoax, Va., Sept. 6, 1784, died in Winchester, Aug. 26, 1851. He was educated at William and Mary college, studied law, and in 1809 settled in Charlotte co., and in 1815 in Missouri, where he became a judge. From 1834 till his death he was professor of law in William and Mary college. He published a work on "Pleading," "Lectures on Constitutional Law," and novels entitled "George Balcombe" and "Gertrude." He left an unfinished novel called "The Partisan Leader," first published in 1837, and reprinted in New York in 1861, under the leading title "A Key to the Disunion Conspiracy."

TUCKERMAN, Henry Theodore, an American author, born in Boston, April 20, 1813, died in New York, Dec. 17, 1871. In 1833 and again in 1836 he went abroad, residing for some time in Italy and devoting himself to literature and art studies. In 1845 he removed from Boston to New York. He was a regular and frequent contributor to numerous periodicals, in which the bulk of his works originally appeared. He published "The Italian Sketch Book" (1835); "Sicily, a Pilgrimage" (1839); "Rambles and Reveries" (1841); "Thoughts on the Poets" (1846), devoted chiefly to masters of the English school (translated into German by Emil Müller); "Artist Life, or Sketches of American Painters" (1847); "Characteristics of Literature" (1849; 2d series, 1851); "The Optimist" (1850), a collection of miscellaneous essays; a "Life of Commodore Silas Talbot" (1851); "Poems" (1851); "A Month in England" (1853); "Memorial of Horatio Greenough" (1853); "Leaves from the Diary of a Dreamer" (1853); "Essays, Biographical and Critical" (1857); "Essay on Washington, with a Paper on the Portraits of Washington" (1859); "America and her Commentators" (1864); "A Sheaf of Verse" (1864); "The Criterion, or the Test of Talk about Familiar Things" (1866); "Maga: Papers about Paris" (1867); "The Book of American Artists" (1867); and "Life of John Pendleton Kennedy" (1871).

TUCKERMAN, Joseph, an American clergyman, born in Boston, Jan. 18, 1778, died in Havana, Cuba, April 20, 1840. He graduated at Harvard college in 1798, and from 1801 to 1826 was pastor of a Unitarian society in Chelsea. He then labored as a missionary among the poor of Boston. In 1812 he was instrumental in forming the first charitable society for the benefit of sailors in the United States, and subsequently the American seamen's friend society, and a "Benevolent Fraternity of Churches" for the support of a city mission, called the "Ministry at Large." He also visited Great Britain, and promoted similar organizations there. In 1830 he wrote a prize essay "On the Wages paid to Females." He published reports to the "Fraternity of Churches" (12mo, 1831; 2d ed., 1832), and "Principles and Results of the Ministry at Large."

TUCSON, a city and the capital of the territory of Arizona, county seat of Pima co., in lat. 32° 12′ N., lon. 110° 52′ W., 370 m. S. W. of Santa Fé, N. M., and the same distance E. by S. of San Diego, Cal., on the route between those places; pop. in 1870, 3,224; in 1875, about 5,000, three fourths of whom are of Mexican origin and speak Spanish. It is situated in the valley of the Santa Cruz river, 2,520 ft. above the level of the sea, about 55 m. S. of the Gila river and 60 m. N. of the Mexican boundary, and is the largest and most important place in the territory. It has the appearance of a Mexican town, with the customary plazas and narrow streets and houses built chiefly of adobe; but with the accession of American population an improvement is taking place. Camp Lowell, a United States military post, is 7 m. distant. There is only one church, Roman Catholic. Nine miles S. of the city is the church of San Xavier, built upward of a century ago by Catholic missionaries. Tucson has a designated United States depository and money-order post office, and an assay office; a commodious and well furnished public school building, with male and female departments and a large and increasing attendance; a seminary and school, under the charge of the sisters of St. Joseph; and a weekly newspaper. The territorial library contains 3,000 volumes. The climate is mild in winter and hot in summer, the average temperature of January being 51° and of July 89°. The business in 1875 amounted to $1,800,000, consisting chiefly in trade with the Mexican state of Sonora, and in supplying the military posts and Indian reservations of S. Arizona.—Tucson is within the "Gadsden purchase," obtained from Mexico by the treaty of Dec. 30, 1853. Its early history is unknown, but it has been a place of some importance for more than a century, and before its acquisition by the United States was a Mexican military post. It was incorporated in 1871.

TUCUMAN. I. A N. province of the Argentine Republic, bordering on Salta, the Gran Chaco, Santiago, and Catamarca; area, about 28,000 sq. m.; pop. in 1869, 108,602. In the west the surface is traversed by the Aconquija mountains, but in other directions there are extensive plains. The mountains abound in copper, silver, and other ores, but the mines are little worked. The most important rivers are the Salado, Tala, and Medinas. There are several shallow saline lakes, and in many places extensive tracts covered with fossil salt. The water of nearly all the streams is brackish. The climate of the plains is hot, but dry and healthful. The soil affords good crops of grain, sugar cane, tobacco, and fruits, and excellent pasturage. The chief exports are cattle and timber. **II.** A city, capital of the province, on the river Tala, in lat. 26° 51′ S., lon. 65° 15′ W., 675 m. N. W. of Buenos Ayres, on a plain 2,490 ft. above the sea; pop. in 1869, 17,438. The streets are regularly laid out but narrow, and most of the houses are of two stories and open into spacious interior courts. The principal church, fronting on the plaza, has two towers and a lofty dome; and there are several other churches, a Franciscan and a Dominican monastery, the college of San Miguel, and other institutions. There are tanneries, manufactories of leather work, and brandy distilleries. It took an important part in the war with Spain, and here, on July 9, 1816, a congress of the La Plata states met and issued a declaration of independence.

TUDELA (anc. *Tutela*), a city of Spain, in the province of Navarre, on the right bank of the Ebro at its junction with the Queiles and at the beginning of the Imperial canal, 156 m. N. E. of Madrid; pop. about 9,000. The Ebro is crossed here by a stone bridge with 17 arches. The Queiles passes through one of the principal squares, where bull fights take place; another square is surrounded by arcades. It has a highly ornamented cathedral, a medical college, and an orphan and foundling asylum. The exports include agricultural products, wool, oil, and wine resembling Burgundy. Few vestiges of the ancient fortifications remain. The Moors held the city from the 8th till early in the 12th century. The French under Lefebvre-Desnouettes were victorious here in June, 1808, and in November Lannes achieved a more decisive victory over Castaños in a battle fought chiefly on the heights above Tudela.

TUDOR, the surname of a line of English sovereigns, consisting of Henry VII., 1485–1509; Henry VIII., 1509–'47; Edward VI., 1547–'53; Mary I., 1553–'8; and Elizabeth, 1558–1603. The family descended from a Welsh gentleman, Owen ap Tudor, who married Catharine of Valois, widow of Henry V. One of their sons, Edmund, earl of Richmond, married Margaret, daughter and heiress of John Beaufort, duke of Somerset, whose father was an illegitimate son of John of Gaunt by Catharine Swynford. The offspring of this connection were afterward legitimated, but excluded from the succession. The only son of Richmond and the heiress of Somerset, Henry, duke of Richmond, on the extinction of the direct male line of John of Gaunt, was accepted by the Lancastrian party as their chief. He was invited over from France to deliver the country from the tyranny of Richard III., whom he overthrew at the battle of Bosworth in 1485, and became king. His marriage with Elizabeth, eldest daughter of Edward IV., in 1486, united the claims of the houses of York and Lancaster. The Tudors were bold, energetic sovereigns, and often despotic; and under them England was prosperous and powerful.—See "A Chronicle of England during the Reign of the Tudors, from 1485 to 1559," by Charles Wriothesley (vol. i., London, 1875).

TUDOR, William, an American author, born in Boston, Jan. 28, 1779, died in Rio de Janeiro, March 9, 1830. He graduated at Harvard college in 1796, visited Europe, and on his return founded the "Anthology Club," and contributed various articles to its journal, the "Monthly Anthology." In 1815 the first number of the "North American Review" appeared under his editorship, and three fourths of the first four volumes were written by him. In 1819 he published "Letters on the Eastern States;" in 1821 a volume of "Miscellanies;" and in 1823 a "Life of James Otis." In 1823 he was appointed United States consul at Lima, and in 1828 was made chargé d'affaires at Rio de Janeiro, where he wrote "Gebel Teir" (Boston, 1829). He was one of the founders of the Boston Athenæum.

TUESDAY, the third day of the week. In the Roman calendar it was called *dies Martis*, from Mars, and its present name is derived from Tiw, the Anglo-Saxon god of war.

TUFA. See Calcareous Springs.

TUFTS COLLEGE, an institution of learning in Medford, Mass., founded by Universalists. The corner stone of the original edifice was laid July 19, 1853, and the building finished in the spring of 1854. It is of brick, 100 by 60 ft., and three stories high. Besides this there are at present three large dormitories furnishing accommodations for 150 students. The college was named in honor of Charles Tufts, who gave it 70 acres of land for a site. Its total endowment now amounts to more than $1,000,000. The institution was opened in August, 1854. In 1867 the divinity school was organized. The first president was the Rev. Hosea Ballou, 2d, D. D., who died in 1861, and was succeeded by the Rev. Alonzo A. Miner, D. D., LL. D. Dr. Miner resigned in 1876, and was succeeded by the Rev. Elmer Hewitt Capen. In the college department there are two parallel courses of four years each. The first is the usual college course, for which the degree of bachelor of arts is given. The second resembles the first, but gives more scope to elective studies, and permits the substitution of the modern languages for Greek. For this course the degree of bachelor of philosophy is given. There is also an engineering course of three years. The full course in the divinity school is three years for bachelors of arts and four years for others; but students are admitted for shorter periods. For theological students tuition and room rent are free. The library of the college contains more than 16,000 volumes and 5,000 pamphlets. The museum contains good collections of minerals, shells, birds, and botanical specimens. In 1875–'6 the collegiate department had 10 professors, 1 instructor, and 73 students, viz.: classical course, 56; engineering, 12; philosophical, 2; resident graduates, 3. The divinity school had 3 professors, 1 instructor, 3 lecturers, and 23 students. The number of graduates of the college was 225; of the divinity school, 21.

TUI. See Poë Bird.

TUILERIES, a royal palace in Paris, between the Seine and the rue de Rivoli, and E. of the Place de la Concorde, so named because it stood on the site of a former manufactory of tiles (Fr. *tuilerie*). It was commenced in 1564 by Catharine de' Medici, who built the central *pavillon de l'horloge*, and the two adjoining wings and their pavilions. Henry IV. added a range of buildings with a lofty pavilion at each end, the whole presenting a façade 336 yards in length by 36 in depth. He also commenced the gallery fronting the Seine connecting the S. extremity of the building with the Louvre, continued by Louis XIII., and finished by Louis XIV. The latter replaced the spherical dome of the *pavillon de l'horloge* by a quadrangular one; and in 1808 Napoleon I. began the northern gallery along the rue de Rivoli, which was completed by Napoleon III., when the Tuileries and the Louvre formed a connected pile, enclosing the Place du Carrousel. The front of the building was imposing, and the interior unsurpassed in magnificence by any other royal residence. After the removal of the court to the palace of Versailles in 1672 no French king lived in the Tuileries until 1789, when Louis XVI. was compelled to remove thither. On Aug. 10, 1792, the people stormed the building and massacred the Swiss body guard. It was the residence of Napoleon during the consulate and empire, and of the Bourbons after the restoration. In July, 1830, it was again taken by the people; and at the expulsion of Louis Philippe in February, 1848, it was for the third time ransacked. It was the residence of Napoleon III., who renovated and greatly improved it. The palace itself, with a small part of both extensions connecting with the Louvre, was destroyed by fire by the communists in May, 1871. The gardens of the Tuileries, extending west to the Place de la Concorde, comprising 50 acres, and among the most attractive public resorts in Paris, suffered severely during the war of 1870–'71, but in 1876 had been thoroughly restored.

TUISCO, Thuisco, Tuisto, or **Teut,** the god whom, according to Tacitus, the ancient Germans revered as the earth-born founder of their nation. He was represented as a gray-bearded man, with uncovered head clad in the skin of an animal, holding a sceptre in his right hand, and stretching out the left. His son Mannus was the father of the progenitors of the three principal tribes.

TULA. **I.** A central government of Russia, bordering on Moscow, Riazan, Tambov, Orel, and Kaluga; area, 11,955 sq. m.; pop. in 1870, 1,167,878. The surface is generally flat. The most important rivers are the Oka, Upa, and Don, the two latter of which are connected by the Ivanovska canal, which forms part of the system that unites the Baltic, Black, and Caspian seas. The soil is fertile, and about two thirds of the surface is cultivated. Iron and woollen and linen goods are manufactured. **II.** A city, capital of the government, on the Upa, 107 m. S. of Moscow; pop. in 1867, 58,150. It has an extensive cannon foundery and manufactory of arms, established by Peter the Great, and upward of 800 private firearms and cutlery workshops.

TULARE, a S. E. county of California, extending from the summit of the Sierra Nevada on the northeast to the summit of the Monte Diablo range on the southwest, and drained by Kern river and several streams that flow into Tulare lake; area, 5,600 sq. m.; pop. in 1870, 4,533, of whom 99 were Chinese. Tulare lake, over 30 m. long and about 20 m. wide, is in the S. W. part. Its valley is fertile. Some gold is found, but the mines are little developed. Agriculture and grazing are the chief pursuits. The Visalia division of the Central Pacific and the Tulare division of the Southern Pacific railroad traverse it. The chief productions in 1870 were 53,605 bushels of wheat, 9,750 of Indian corn, 85,110 of barley, 8,685 of potatoes, 660,645 lbs. of wool, 37,490 of butter, and 4,419 tons of hay. There were 4,590 horses, 36,167 cattle, 147,301 sheep, and 15,403 swine; 3 flour mills, and 3 saw mills. Capital, Visalia.

TULIP (Pers. *thulyban;* written *tulipan* by the old authors, and Latinized as *tulipa*), a genus of plants of the lily family, of which numerous cultivated forms are derived from several distinct species, all natives of the old world. They have a coated bulb, from which appears in spring a one- to three-leaved stem, terminated by a single, erect, large, showy flower; the six parts of the flower are separate, broad, and not spreading; six stamens with erect anthers, and a triangular ovary, with sessile stigmas, which ripens into a similarly shaped, three-celled, and many-seeded pod. The garden, florists', show, or late tulips, as they are variously called, are from *tulipa Gesneriana*, the species being named in honor of Gesner, who described the plant in 1559 from specimens raised from seed sent from the Levant; the stems are taller than in any other species (about 30 in.), with the divisions of the flower very obtuse, and in the wild state marked with yellow and violet. The cultivation of this plant rapidly spread in the Netherlands, and almost innumerable varieties were obtained from seed; that country is still the centre of the culture of this and many other bulbs, and supplies the rest of the world. About the middle of the 17th century the tulip became the object of a remarkable commercial excitement or mania, and the bulbs were bought and sold at such enormous prices (the equivalent of $6,000 was paid for a single bulb) that the government was forced to limit the price for any one bulb to 200 francs; these extraordinary sales were not always real, with a transfer of the bulb, but they served to speculate upon, like stocks in the exchange. So great has been the change in popular taste that at present, in this country at least, it is very rare to see a bed of choice named varieties of show tulips. The fanciers make several classes, the principal of which are: bybloemens, in which the flowers have a white ground broken with various shades of purple and other colors; bizarres, with a yellow ground, variegated with other colors; Baguets, with the flowers white at base and broken with rich brown; incomparable Verports, with cherry or rose ground, white bottoms, and marked with shining brown. Breeders are bulbs raised from seed which are at first selfs, or all of one color, without any variegation whatever; by continuous cultivation they finally "break," or become variegated, the time varying from one to 20 years, and even at the end of the longer period the result may be worthless. These late tulips bloom in the northern states about the last of May, but there is a set of varieties which bloom three weeks earlier. These are from *T. suaveolens* of southern Europe, with stems less than a foot high, and acute petals; one of the most valued of these is "Duc Van Thol," usually red bordered with yellow, and presenting several subvarieties. There is a long list of named early sorts, from pure white to dark violet, with innumerable variegations; there are also double varieties of these, which are not pleasing singly, but planted in clumps make brilliant masses of color. The parrot tulips are varieties or crosses of *T. Turcica*, from Turkey; they are of dwarf habit, the petals curved and fantastically fringed, and colored with yellow, red, and a large admixture of green; the form and coloring readily suggest the popular name. A few species, little if any changed by cultivation, are sometimes seen in gardens; among these are *T. cornuta*, with singularly attenuated petals, *T. oculis solis*, vermilion, with a deep violet (called black) eye, and others. The bulbs are imported each autumn in large quantities from Holland. A perfect and mature bulb contains a well developed bud, which the next spring will

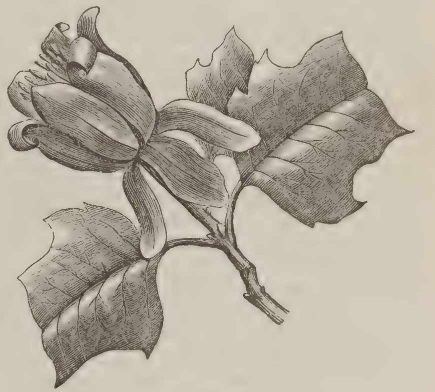
Early Tulip, Duc Van Thol.

rapidly push up and produce leaves and flower; it also contains, between the scales, another bud, which during the brief growing season, while the first named is blooming, will increase rapidly, replacing that, and be ready to bloom the next year; besides these, the bud of a third generation may be found, ready in time to take the place of the second bud. When a tulip bulb is planted, it produces its flower and leaves; its foliage, after flourishing for a while, suddenly dies off, and a bulb may be dug up apparently like the one planted; but that has been expended in producing the flower, and this bulb is due to the increase of the second or replacing bud, which will be found to contain the rudiments of next spring's bloom. At the base of the bulb appear small offsets or bulblets, which, if broken off and cultivated for several years, will grow to a flowering size, and reproduce the peculiar variety; in Holland the number of these bulblets is increased by cutting off the flower buds as soon as they appear.—In careful tulip culture, the bed is made very light and rich, and the bulbs are set in October, 8 in. apart and 3½ in. deep; some take pains to envelop each bulb in sand; the bed is covered with litter, and left until spring, when it is uncovered; as the flowers are about to open, the bed is covered with an awning of cotton cloth, to prevent the sun from injuring the flowers, and thus prolong their duration; when the bloom is over, the seed vessels are cut off, and the plants cultivated until the leaves fade, which they will do in a few weeks, when the bulbs are taken up, dried, and kept in a cool, dry place until time to plant again. Early sorts are often left in the ground year after year; and though they do not give so fine a bloom as when the bulbs are lifted, they make acceptable spring flowers. Like other bulbs, tulips are readily forced in the greenhouse or in window culture (see HYACINTH); the early sorts are preferred for this, and three bulbs may be put into a six-inch pot.

Parrot Tulip.

Late or Show Tulip.

TULIP TREE, the popular name for *liriodendron tulipifera*, a large tree of the magnolia family; one of its distinctive characters, its large and showy flowers, being recognized in its botanical and common names. The genus (named from Gr. λίριον, a lily, and δένδρον, a tree) is exclusively American, and includes only this species. It is found from Canada to Florida, and is more abundant in parts of the west, as Michigan and southern Illinois, than at the east; with the exception of the buttonwood, it is the largest of our deciduous trees, reaching the height of 140 ft., with a diameter of 8 or 9 ft. The bark on young branches is light brown and smooth, but on old trees it is much broken by longitudinal fissures. In spring the development of no tree can be studied with greater interest; as the large leaf buds open they are found to be covered by two stipules, coherent by their edges to form a sac, and beneath these the young leaf, to which they belong, will be found closely folded, and its petiole bent over; beneath this is another leaf similarly covered and packed away, and so on; as the leaf develops, the stipules increase in size, and soon fall away, leaving a scar just above the petiole. The leaves, on long petioles, are 4 in. or more across, with two lobes near the base and two at the apex, where the leaf appears as if it had been abruptly cut off, leaving a very broad, shallow notch. The flowers are solitary and terminal; the bud is enclosed by a sheath which is pushed off as the flower opens; they consist of three long



Tulip Tree (Liriodendron tulipifera).

reflexed sepals, and six petals, which are arranged in two rows, to form a bell-shaped corolla, 2 in. or more long, within which are numerous stamens, surrounding a cone-like mass of pistils crowded upon a long slender axis. In fruit the pistils ripen into woody one- or two-seeded keys, which fall away from the axis. The petals are greenish yellow, marked with orange, and have an orange spot at the base. The bark, especially that of the root, is bitter and aromatic, and sometimes used as a stimulant tonic. The wood, often called white wood, though it becomes yellowish upon exposure, is soft and easily worked, and is put to almost as many uses as that of the white pine; it is easily bent to any required shape, which makes it useful in building circular staircases and other curved work; it is much employed in carriage building for panels, and in cabinet work, especially for drawers. In localities where it is the most available timber, it is employed in building. The western lumbermen almost invariably call the tree poplar ("popple") or yellow poplar; an unfortunate misnomer, as it has no resemblance to or botanical relationship with the poplars. The tulip tree is pleasing when young, and when full grown forms a very stately object. There are several varieties in which the leaves deviate from the usual form, and one in which they are handsomely variegated with yellow; but the markings do not hold under our hot suns. Trees transplanted from the woods, unless they are very small, do not succeed, and this has given the impression that the tree is difficult to manage. It is easily raised from seeds, and nursery trees, produced in this way and transplanted a few times, may be removed without difficulty.

TULL, Jethro, an English agriculturist, born about 1680, died in January, 1740. He owned an estate near Hungerford, on the borders of Oxfordshire and Berkshire, and observing the advantage of cultivation of plants in rows, and of stirring and pulverizing the soil between them, he introduced this system of cultivating the soil. But he adopted the erroneous principle that manure was not essential, as finely pulverized earth and moisture were sufficient for the growth of plants. This ruined him, and brought discredit upon his system. He published a treatise on his new mode of cultivation (1731), and detached essays, which were collected in 1751, and republished by William Cobbett in 1822. (See AGRICULTURE, vol. i., p. 203.)

TULLE, a town of France, capital of the department of Corrèze, and formerly of Lower Limousin, at the junction of the Solane with the Corrèze, 115 m. E. N. E. of Bordeaux; pop. in 1872, 11,848. It has fine quays and promenades, a suburb, many bridges, a cathedral remarkable for its tower, and a celebrated government factory of firearms. Among its manufactures are paper, playing cards, nails, leather, and coarse woollens; and it has a trade in horses, game, and neatsfoot oil.

TULLIUS, Servius. See SERVIUS TULLIUS.

TULLOCH, John, a Scottish clergyman, born at Tibbemuir, Perthshire, in 1822. He was educated at the university of St. Andrews, and in 1844 was ordained a minister of the church of Scotland, with a charge at Dundee. Afterward he visited Germany, and studied speculative theology. In 1849 he removed to the parish of Kettins in Forfarshire, and in 1854 was appointed principal of St. Mary's college in the university of St. Andrews, which office he still holds (1876). In 1855 he received a Burnett prize of £600 on the "Being and Attributes of God." He has published "Leaders of the Reformation" (1859); "English Puritanism and its Leaders" (1861); "Beginning Life: Chapters for Young Men" (1862); "The Christ of the Gospel and the Christ of Modern Criticism: Lectures on M. Renan's *Vie de Jésus*" (1864); and "Rational Theology and Christian Philosophy in England in the Seventeenth Century" (2 vols., 1872).

TULLUS HOSTILIUS, the third king of Rome, said to have reigned from about 673 to about 641 B. C. The most memorable event of his reign, according to the legend, is the war with Alba, celebrated by the combat between the Horatii and the Curiatii, and the consequent acknowledgment by the Albans of Roman supremacy. In the war against Fidenæ, an Alban army was led to the assistance of Rome by Mettus Fuffetius, the Alban dictator, who intended to go over to the enemy at the critical moment. Tullus discovered the treachery, had the traitor torn in pieces from chariot wheels, razed Alba to the ground, and transferred the inhabitants to Rome, where the great mass of them became the Roman *plebs*. After these successes Rome was afflicted with a pestilence, and the king himself was seized with the disease. Having found the formula with which Numa had sacrificed to Jupiter Elicius, he attempted to call down the god, but fell into an error, and the god destroyed the king and his household by lightning.

TULLY, William, an American physician, born in Saybrook, Conn., Nov. 18, 1785, died in Springfield, Mass., Feb. 28, 1859. He graduated at Yale college in 1806, studied medicine, and in 1808 settled at Milford, Conn. He removed about 1815 to Upper Middletown, now Cromwell, Conn., where he became intimate with Dr. Thomas Miner, whose views in relation to the nature and treatment of spotted fever he adopted; and in 1823 he published with him the essays known as "Miner and Tully on Fever." In 1824 he was elected president and professor of materia medica in the medical institution at Castleton, Vt. In 1827 he removed first to Albany, and afterward to Castleton. He was professor of materia medica in the medical institution of Yale college from 1830 to 1841, when he resigned. In 1851 he removed to Springfield, Mass., where he prepared a work on materia medica (vol. i. in 2 parts, Springfield, 1857-'60).

TULTCHA, or **Tultsha** (anc. *Ægissus*), a town of Bulgaria, on the right bank of the Danube, 6 m. above the junction of its Sulina and St. George's arms, 12 m. S. S. W. of Ismail, and 45 m. W. of Sulina; pop. variously estimated between 13,000 and 20,000. It is a port of considerable commercial importance. The former fortress was damaged by the Russians in 1789 and 1791, and utterly destroyed in 1828, after which the present town was laid out. It was occupied by the Russians during the spring of 1854. Darius crossed the Danube in the vicinity of ancient Ægissus in his expedition against the Scythians.

TUMOR (Lat. *tumere*, to swell), an excessive growth of tissue confined to a limited region, not inflammatory. Tumors are described as "benign" or "malignant," as "homologous" or "heterologous." A benign tumor is one which does not, except by its mechanical action, interfere with life, and has generally no tendency to recur after removal. A malignant tumor is one produced by or inducing a constitutional taint, and usually reappearing after removal. A homologous tumor is one the structure of which is like tissues normally existing in the body. A heterologous tumor is one composed of tissues unlike to those normally present. Though a foundation of truth lies in this nomenclature of sufficient strength to have misled most physicians, our present knowledge of the histology and clinical histories of these growths has clearly shown that these distinctions are erroneous. The extremes are well marked, but the boundary line is irregular or confused. To what the growth of tumors can be ascribed is undetermined. That it is due to a perverted nutrition is certain, but how or why cannot be explained. The exciting cause is always mechanical, either from without or within the body; the predisposing cause, apart from heredity or mal-nutrition, specific or of other character, is obscure. With such a knowledge of tumors, an accurate classification is impossible, but one can be made which will greatly assist in the diagnosis, prognosis, and treatment of these growths, and also in the examination of their minute structures, viz.: 1, cystic tumors; 2, those made up of simple or composite tissues, aggregated or arranged as usually found in the adult body; 3, those made up of simple tissues, aggregated or arranged in a manner deviating widely from the normal, the cell element largely predominating. A cystic tumor is one having a limiting membrane which exists normally, or is formed by a condensation of surrounding tissue, or is a production of new tissue. The contents may be fluid or solid. Housemaids' knee is an example of a fluid cystic tumor, the limiting membrane of which exists normally. The sebaceous tumor of the scalp is an example of one which is solid, produced by an obstruction in its duct to the secretion of a gland. A blow on the head may cause an effusion of blood beneath the scalp, which, by its outward pressure and irritation, can produce and excite the formation of a cyst wall. In this class will be comprised most ovarian tumors, kidney cysts, congenital tumors containing hair, &c. To the second class belong all tumors of a fibrous, fatty, or cartilaginous nature, either alone or combined, and those made up of composite tissues, such as the vascular and glandular tumors. To the third class belong such growths as consist mainly of cells, or of cells mingled with other tissues in an irregular and abnormal manner: tubercle, sarcoma, cancer, &c. Making use of the terms employed in the nomenclature mentioned above, tumors in the first and second classes are homologous and generally benign; those in the third class are heterologous and as a rule malignant.—The chief interest, as regards prognosis, centres upon tumors of the third class. Opinion is divided as to whether cancer, using this term in its common signification, and taking this member of the class as the most important surgically, is primarily a local disease affecting the constitution only secondarily, or whether it is merely the local manifestation of a preëxisting constitutional taint.

TUNBRIDGE, or **Tonbridge**, a market town of Kent, England, on the Tun, near its entrance into the Medway, 11 m. S. W. of Maidstone; pop. in 1871, 8,209. It consists for the most part of one long and well built street, and contains six churches, an endowed grammar school lately rebuilt, and several literary and charitable institutions. There are ruins of a gateway flanked by round towers, once belonging to the castle built by the first earl of Clare and Hertford in the 11th century. The refectory of a priory founded by the same earl is still standing. Tunbridge has manufactures of gunpowder and fancy wooden wares, and a considerable trade in coal and lumber.

TUNBRIDGE WELLS, a market town of Kent and Sussex, England, in a beautiful country, 15 m. S. W. of Maidstone; pop. in 1871, 19,410. It is a fashionable watering place, and consists chiefly of clusters of houses on detached eminences, and of a parade paved with pantiles in antique style, and lined with fine trees on one side, and on the other with assembly rooms, libraries, and shops. The surrounding country abounds in mineral springs. The one to which the place owes its origin is a light pure chalybeate, and the water is considered remarkably efficacious in cases of weak digestion.

TUNGSTEN (Swed. *tung*, heavy, and *sten*, stone), a metal existing in the form of an acid combined with lime in the mineral scheelite or tungstate of lime, and also combined with iron and manganese in the mineral wolfram. Tungstic acid was discovered by Scheele in 1781, and metallic tungsten two years later by the brothers D'Elhujar. Its German name *Wolframium* gives its symbol, W. It is obtained as a heavy iron-gray metal, very hard and difficult of fusion, and of the high specific gravity 17·6, by intensely heating tungstic acid made into a paste with oil, in a crucible lined with charcoal, for some hours. The tungstic acid is procured by decomposing the tungstate of lime with hydrochloric acid, which dissolves the lime and leaves the tungstic acid. The chemical equivalent of tungsten is 184.—Tungsten combines with several other metals, forming alloys of interest. Its combination with cast iron is remarkable for its extraordinary hardness; and it is said that cast steel containing 10 per cent. of tungsten is greatly improved in tenacity, hardness, and susceptibility of taking a fine temper. Notwithstanding its reputed qualities, tungsten steel has not been generally introduced, and comparatively little is made.—Of the two oxides of tungsten, WO_2 and WO_3, the latter only, or tungstic anhydride, is of particular interest. This occurs native in bright yellow cubes, also as an earthy substance like ochre at Lane's mine, Monroe, Conn., Cabarrus co., N. C., and a few other places. But the usual form of the acid is in the combinations already named, and of these wolfram is the most common ore of the metal. This is a brownish black mineral, of metallic lustre, of hardness 5 to 5·5, and specific gravity 7·1 to 7·55. It is often found associated with tin ore in Cornwall, Saxony, Bohemia, and France. In the United States it has been found at Monroe, Conn., with native bismuth, galena, blende, &c.; also at Trumbull in the same state, and near Mine La Motte, Mo., and Blue Hill bay, Me. Tungstic acid is also found in combination with lead, forming the mineral scheeletine, and artificial tungstate of lead is prepared as a pigment resembling white lead. The following are some of the attempted applications of the compounds of tungsten to economical purposes: tungstic acid for coloring yellow; oxide of tungsten for coloring blue; tungstate of soda in dyeing and calico printing, and as a substitute for stannate of soda. The compounds of tungsten have been thoroughly studied by Roscoe and Zettnow, but none of them possess particular interest beyond those already described.

TUNGUSES, a tribe of N. E. Siberia, of Mongolian origin, extending as far W. as the Yenisei and as far E. as Anadyrsk, in lon. 171°. They number about 70,000. Among their allied tribes are the Monzhurs and the Gilyaks and others of the Amoor. The Mantchoos belong to the Tungusic stock. The Tunguses proper and their congeners the Lamuts are well disposed, and mostly belong to the Greek church and pay tribute to the czar. They are generally divided into reindeer, horse, and dog Tunguses; but they are chiefly devoted to the reindeer, which they use for riding and for carrying freight, while other tribes use them chiefly in sledges. The Tunguses and the Lamuts are very slender, and have dark olive complexions, no beards, straight black hair, and oblique eyes. Men and women wear almost the same rich costume of fur hoods and pantaloons, short deer-skin boots, and highly ornamented buckskin aprons. They differ greatly from the Tchuktchis and Koriaks, though leading the same nomadic life; while among the latter there are men owning thousands of reindeers, one possessing 300 would be deemed immensely rich among the Tunguses. Unlike most other tribes, they never break up their tents without leaving a pole as a landmark for resuming the same habitation on returning from their wanderings. The Russian traders of the sea of Okhotsk derive most of their supply of Siberian squirrel skins for the European markets from the Tunguses and Lamuts in that region.

TUNICA, a N. W. county of Mississippi, bordering on the Mississippi river, which separates it from Arkansas, and intersected by the Coldwater river and other streams; area, 750 sq. m.; pop. in 1870, 5,358, of whom 4,127 were colored. The surface is flat, and in many places swampy, and the soil fertile. The chief productions in 1870 were 4,500 bushels of wheat, 2,000 of oats, 1,500 of barley, 82,155 of Indian corn, and 6,424 bales of cotton. There were 240 horses, 645 mules and asses, 413 milch cows, 1,409 other cattle, 33 sheep, and 1,812 swine. Capital, Austin.

TUNICATES. See MOLLUSCOIDS.

TUNIS. **I.** One of the Barbary states of N. Africa, bounded N. and E. by the Mediterranean, S. E. by Tripoli, S. by the desert of Sahara, and W. by Algeria, between lat. 32° 20′ and 37° 20′ N., and lon. 7° 20′ and 11° 30′ E.; extreme length about 350 m., general breadth 130 m.; area, about 45,000 sq. m.; pop. about 2,000,000. Besides the capital, of the same name, the chief towns are Kairwan, Susa, Hammamet, Bizerta, Kef, and Sfax. The coast line is irregular, and has three extensive indentations, forming the gulfs of Tunis, Hammamet, and Cabes (Syrtis Minor). The only considerable river is the Mejerda (anc. *Bagradas*), which falls into the gulf of Tunis after a N. E. course of about 200 m. Near its mouth, and for some distance W. of it, are several large lagoons. The Shot Kebir (anc. *Palus Tritonis*), over 100 m. long, and the Shot Gharnis, further W., over 50 m. long, in the southern part of the country near the Sahara, are marshy depressions which become nearly dry in summer. The interior of Tunis is but little known. The N. W. portion is mountainous, the summits having a height in many places of 4,000 or 5,000 ft. The mountains are well timbered, and have many tracts of cultivated land and olive plantations on their lower slopes. An extensive plain or table land, 100 m. long by 30 m. broad and quite level, extends from this region to the gulf of Hammamet; it is nearly destitute of trees, and is used by the Arabs for pasturing their horses and camels. S. of this plain the country is believed to be nearly desert, though in ancient times it was celebrated for its fertility. Silver, lead, and copper are found in the mountains. The climate is very healthful; rain falls at intervals between November and April, but droughts prevail during the rest of the year. Wheat, barley, and maize are raised, but dates furnish a great part of the subsistence of the inhabitants. Olives, tobacco, cotton, indigo, and various drugs and dyes are grown; and the fruits of southern Europe are abundant. The principal domestic animals are horned cattle, mules, and camels; the breed of horses, once famous, has been allowed to degenerate. The tunny and sponge fisheries on the coast are important. The lion, panther, lynx, ounce, wolf, and boar are the principal wild animals found in the country.—The people of the interior are principally Arabs and Kabyles, while those of the coast comprise Turks, Moors, Jews, and Christians, with various degrees of mixture. They are generally good-looking, but very ignorant. The language is a dialect of Arabic, but an Italian idiom is used by the traders. The Arabs resemble the Bedouins of Arabia in their mode of life, but are inhospitable to strangers. The Kabyles live on the mountains in villages of rudely constructed huts, and subsist chiefly on dates, bread, and milk. Arms are carried by all classes, and on the borders of Algeria the inhabitants do not acknowledge allegiance to either government. The religion is strict Mohammedanism. The principal manufactures are woollen fabrics, particularly the red caps so much worn along the shores of the Mediterranean; considerable numbers of skins are tanned and dyed; and trade is carried on with Europe and the interior of Africa. The government of Tunis, though nominally dependent on Turkey, and called a regency, is in reality a perfectly independent and absolute despotism. The sovereign is known as the bey. He pays no tribute, but is nominally restrained from making war or ceding territory without the consent of the sultan. The Turkish law of succession to the throne prevails. There are many ancient ruins in different parts of Tunis, more particularly in the valley of the Mejerda, where at Dukhah (anc. *Thugga*) are temples, an arch, cisterns, baths, barracks, gates, theatres, an aqueduct, and many inscriptions. The great aqueduct which conveyed the water 52 m. from the mountain of Zagwam to Carthage can still be traced along the whole line, while some remaining portions rise to the height of 98 ft.—Under the Romans this country formed the province of Africa, and was divided into Zeugitana in the north and Byzacena in the south; and its most important cities were Carthage, Utica, Hippo Zarytus (Bizerta), Hadrumetum, Leptis Minor, Thapsus, and Zama. In A. D. 429 it was taken by the Vandals, and a century afterward became subject to the Greek empire, under which it remained till N. Africa was overrun by the Mohammedans in the latter part of the 7th century. Early in the 13th century it became independent. Louis IX. of France in 1270 made an unsuccessful crusading expedition against it, and died before the capital. In 1535 Charles V., after defeating the pirate Khair ed-Din Barbarossa and capturing Goletta and the city of Tunis, made the country tributary to Spain; but in 1574 it was conquered by the Turks. The Moors ultimately enforced their right of electing their own bey, agreeing only to pay a certain tribute to the sultan at Constantinople. The pirates of Tunis subsequently became very daring, but in Cromwell's time received severe chastisement from the British under Admiral Blake, and afterward from France and Holland. In 1816 the Tunisians agreed to renounce piracy and Christian slavery. Under Ahmed Bey (who succeeded in 1837) and his successors, Mohammed Bey (1855) and Mohammed Sadyk Bey (1859), various reforms were effected, including the suppression of the slave trade and of many monopolies and oppressive taxes, the establishment of military conscription and of mixed tribunals, and the creation of a municipal government for the capital. French influence has long been predominant in the country. **II.** A city (anc. *Tunes* or *Tunis*), capital of the state, on the W. side of a lagoon near the mouth of the river Mejerda, connected with the gulf by the narrow channel of Goletta, 400 m. E. of Algiers, in lat. 36° 46′ N., lon. 10° 9′ E.; pop. estimated at 120,000. It is surrounded by a double wall 5 m. in circuit, and defended by a strong castle, which commands the approach from the sea, and by several forts. Its appearance from a distance is imposing, but the streets are narrow and dirty, and the houses generally consist of a single story without windows on the exterior. The town is well supplied with water. Among

The Bey's Palace, Tunis.

the principal buildings are the bey's palace, many handsome mosques, and several large barracks, one of which has room for 4,000 men. There are Moorish schools and a college, a Roman Catholic church and convent, a Greek church, a theatre, and public baths and bazaars. The leading manufactures are woollen cloths and caps, embroidery, leather, and essences of musk, rose, and jasmine. The trade is extensive, comprising exports of oil, caps, soap, grain, wool, hides, cattle, sponges, wax, gold dust, and ivory, and imports of cotton, linen, and woollen goods, tin, lead, iron, coffee, sugar, and spices. The depth of water at Tunis is only 6 or 7 ft., and vessels lie in the gulf and discharge by lighters. In 1873, 1,272 vessels of 121,957 tons entered the port. Tunis is not far from the site of ancient Carthage, and is itself a place of great antiquity.

TUNKERS. See DUNKERS.

TUNNEL, a subterranean or subaqueous way, constructed for purposes of passage. In mining, the term is often applied to horizontal excavations, especially to such as are known by the designations gangway, heading, drift, and adit, used as underground roads or for the passage of water. (See ADIT.) Herodotus mentions a tunnel in the island of Samos, cut through a mountain 150 orygia (900 ft.) high. Its length was seven stadia (4,247 ft.), and its cross section 8 ft. high by 8 ft. wide. In Bœotia a tunnel was constructed for the drainage of Lake Copais. When Cæsar arrived at Alexandria, he found the city almost hollow underneath from the numerous aqueducts; every private dwelling had its reservoir, supplied by subterranean conduits from the Nile. The aqueducts of the ancient Romans, and of the Peruvians and Mexicans, included remarkable tunnels. (See AQUEDUCT.) Among the many Roman aqueducts on which tunnels were built were the Aqua Claudia, of which 36½ m. passed underground; the Aqua Appia, built in 312 B. C., 11,190 Roman paces in length, 11,130 being underground and arched; and the Aqua Virgo, 14,105 paces long, 12,865 underground. A tunnel was begun in 398 B. C. to tap Lake Albanus, at the instance, Livy tells us, of the oracle of Delphi. It was 6,000 ft. long, 6 ft. high, and 3½ ft. wide. Fifty shafts were sunk on its line, and the work was finished within one year, though it was driven through the hardest lava. A similar work of greater magnitude was undertaken to connect Lake Fucinus (now Celano) with the river Liris (now Garigliano); 30,000 men were employed on it for ten years, and it was finished at a vast expense A. D. 52. A minute account of the modern clearing out of this work by the Neapolitan government may be found in "Blackwood's Edinburgh Magazine," vol. xxxviii., p. 657. The accuracy of the surveying in these works is astonishing when we consider the rudeness of the instruments. Among those used in levelling by the Romans were the *libra aquaria* and *dioptra*, of which we have no clear description. The *chorobates* seems to have been preferred. It consisted simply of a rod or plank about 20 ft. long, mounted on two legs, at its extremities, of equal length. The rods or legs were secured by diagonal braces, on which were marked correctly vertical lines. A plumb line attached at each extremity, and passing over these diagonal braces, indicated whether the instrument was level. When the wind prevented the plumb bobs from remaining stationary, a channel in the upper edge of the horizontal rod was filled with water, and if the water touched equally both extremities the level was supposed to be correct; and then the observation of the descent or elevation of the ground was made with accuracy.—Tunnelling might be classed under four general heads: 1, ancient tunnelling, to which we have just referred; 2, modern tunnelling through soft ground (clay deposit, &c.) and loose rock, requiring arching; 3, modern tunnelling through solid rock before the introduction of machinery; 4, modern tunnelling through solid rock with the aid of machinery. The art of tunnelling at the present day constitutes a profession in itself, new developments succeeding each other with great rapidity. Figs. 1 and 2 show cross sections that may be adopted in tunnelling: fig. 1 through rock tenacious enough to require no artificial support; fig. 2 where arching may be found necessary. These examples are from plans adopted in the construction of the Musconetcong tunnel, New Jersey, on the Lehigh Valley railroad extension, finished in 1875.—*Tunnelling through Soft Ground.* Under the designation "soft ground," technically so called, the miner includes all such material as clay, earth deposit, &c., which, if tunnelled through, requires a temporary timber arch to

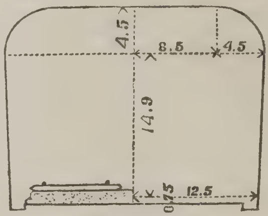


FIG. 1.

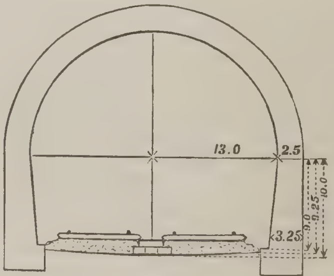

FIG. 2.

hold it in place, until the permanent brick or stone arching is built. Loose rock, as its name indicates, is rock either so seamy and broken by folding or compression, or so disintegrated, as to require an arch, generally much lighter than those necessary in soft ground. According to the method generally adopted in driving a tunnel through soft ground, the first step is, if practicable, to open out a small bottom heading or adit, for the double purpose of draining the ground above and making an opening through which to carry away the material subsequently excavated; this heading also is required for passing in the materials used in arching. Often, however, owing to long and heavy cuttings necessary in the outside approaches to a tunnel, it is deemed advisable to begin with a top heading before the bottom bench of the open cut is brought up to the face of the proposed work. If a bottom heading has been driven (and it is generally best to do so when practicable in soft ground, while the opposite rule holds in tunnelling through hard rock), one of the methods of subsequent enlarging that may be used is shown in figs. 3, 4, and 5. These represent the English plan, so called, it being the one generally adopted in England. For a full description of this method of enlarging, see the "Engineering and Mining Journal," vol. xix., p. 392; also Simms's "Treatise on the Blechingly and Saltwood Tunnels." Fig. 3 shows the bottom heading driven, with a section excavated and ready for arching. The enlarging and arching of a tunnel to its full size is generally done in lengths or sections. If there is no top heading previously driven, 15 or 20 ft. of an advanced heading is excavated at the top of the proposed work (shown in figs. 3 and 4). Heavy longitudinal bars of timber are then successively put in, beginning with those numbered 3, 6, and 7. The miners gradually work down, putting in a temporary arch of timber. When this is done, and foundations have been dug for the succeeding masonry, the masons take the place of the miners, and run up an arch under the timber, which is then withdrawn during the excavation of the next section, and the spaces left are securely blocked up with pieces of timber or stone. In some methods of tunnelling, it is deemed more secure to brick the timber in and leave it in place, though at a considerable cost, especially when it is necessary to bring all the heavy timber down a shaft or slope, and through a long distance underground. Shafts are often sunk, and sometimes slopes, so that the work may be attacked from several points at once. Fig. 5 shows the arch built, and is divided into two portions: that on the left shows the completed tunnel, with the ballast in place and the track laid; that on the right shows the arch in place, and the supporting timbers struck, but still undrawn. Where the ground is very treacherous, and much water is encountered, an inverted arch is often put in across the bottom of the tunnel, to withstand the pressure from below. Other methods are in vogue on the continent of Europe. A description of a new system of tunnelling by the use of iron centres, in place of timber, devised by himself, may be found in Ržiha's work, cited below. — *Tunnelling through Rock.* One of the methods of tunnel-

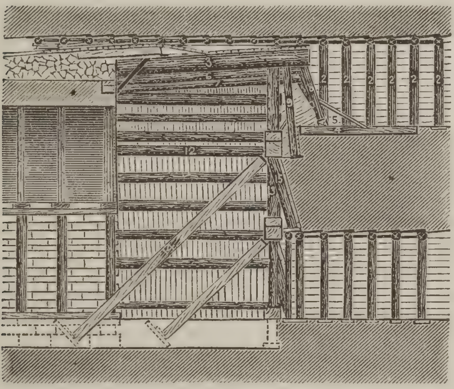

FIG. 3.

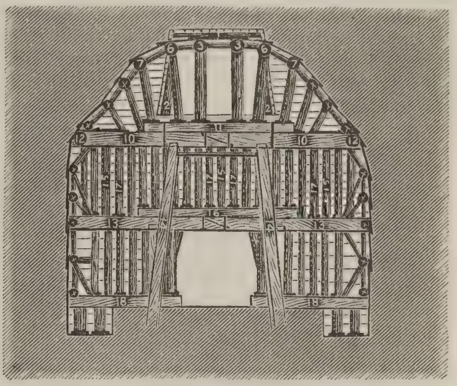

FIG. 4.

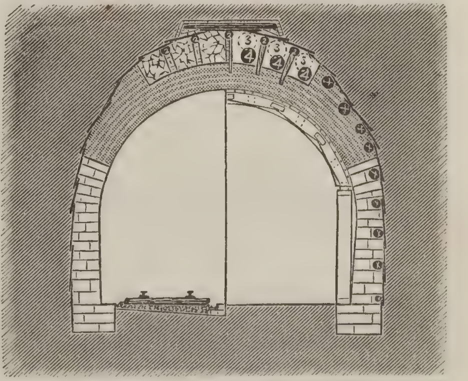

FIG. 5.

ling through loose rock, with subsequent timbering and arching, is shown in figs. 6 and 7; it is the one most used in America, and is expeditious, though probably more expensive than the European systems. The timbers 1 and 2 are put in to support the roof and sides when the top heading (which is generally preferred through rock) is driven; the "legs" (2) are occasionally braced by a bar (3), which is supported by a raker (4), while the sides are being dressed down when the tunnel is enlarged and arched. The space between the timber and the rock above, and between the masonry and the timber (which latter in this work should be left in place), is packed tight with fragments of stone, to prevent a sudden fall or stress being brought to bear on the masonry.—Tunnelling through solid rock by hand labor is still, in many cases, held to be more economical than by machinery. It is certainly so, as yet, in the case of small tunnels through a comparatively soft rock, where the necessary cost of a plant of air drills and compressors would be in excess of the economy in time gained by their use. In driving a tunnel through rock, an advanced heading is first driven either at bottom or top; and this may either be of the full width of the proposed excavation, or narrower. The heading is always the most difficult and expensive part of the work; for whether it be driven at top or bottom, the miner, in removing the remaining portion of rock, of course has much less resistance to contend against in blasting. Removing the top rock or the lower "bench" is more like open-air quarrying. Longer holes can be drilled, and heavier charges of powder used. At the present day, however, most heavy tunnel work is carried on with the aid of machine drills, driven by compressed air, which, on being liberated after acting as a motor, serves to ventilate the work. Since the introduction of machinery, the rate of driving attained in tunnelling has been greatly increased. Machine drilling was born of the necessity for some more rapid method of executing certain works, deemed almost too heavy to be accomplished by ordinary means. These were, in Europe, the Mont Cenis tunnel (see Cenis, Mont), and in America, the Hoosac tunnel in Massachusetts. Various types of drills have been invented and tried abroad; among them the Sommeiller, Dubois-François, Sachs, Osterkamp, Brydon Davidson and Warrington, Azolino dell' Acqua, Ferroux, McKean, and others. Among compressors that of M. Colladon of Geneva may be particularly noted. At Mont Cenis the air pumps were worked by hydraulic power. The perforators used there were built partly from designs already presented, but improved with original modifications made by the engineers in charge, Messrs. Sommeiller, Grandis, and Grattoni. A description of the Sommeiller machines may be found in the *Portefeuille économique des machines* (1863). The Mont Cenis tunnel was begun by hand labor in 1857, and finished in 1871, at a total cost of about $15,000,000. The following table, from M. Opperman's *Nouvelles annales de la construction* (1869), shows the rate of advance in that work by hand, and the increased rate attained immediately after the first introduction of machinery down to 1865, working throughout with two headings:

The St. Gothard tunnel, also through the Alps, is now (1876) in progress. From a late paper on the subject by Daniel K. Clark, M. Inst. C. E., London, we obtain the following general facts concerning it. The length of the tunnel is to be 16,295 yards or 9¼ m. The contract prices sum up to a total estimated cost of £1,896,945. Construction was begun in the autumn of 1872, and the total progress attained (two headings) up to Aug. 31, 1875, was as follows:

YEARS.	By band, yards.	By machines, yards.	Total, yards.
1872	132	....	.....
1873	205	972	.....
1874	....	1,951	.....
1875	....	1,824	5,084

The heading is driven at the top, about 8 ft. square, dynamite being used as an explosive. Dubois-François perforators were first used, making an average advance of 6·63 lineal feet a day. They were succeeded by Ferroux's, the daily advance being raised to 10·11 ft. Subsequently the machines of two or three inventors, Dubois-François, McKean, and Ferroux, were placed and worked together on the same carriage; and it is said by M. Louis Sautter, in an official report published in the *Revue industrielle*, Aug. 18, 1875, that the improved McKean drill has proved to be decidedly superior to any of its competitors; its best work on competition, with 6½ atmospheres of pressure, was a penetration of 12 in. a minute. While actually at work, its rate will vary from 3 to 8 in. a minute, with about 800 strokes. The power is derived from water through the agency of turbines. The cylinders or air pumps of the compressors are 18·1 in. in diameter, and the stroke is limited to 17¾ in., in order that the mean speed of piston may not exceed 266 ft., or 90 revolutions a minute, the turbine making 390 turns. The compressed air is cooled on Dr. Colladon's system; every piece that is in contact with the air when undergoing compression being cooled by currents of cold water, passed through air-tight envelopes. It is calculated that at the present rates of advance the St. Gothard tunnel may be finished during the summer of 1879, or within seven years from the date of M. Favre's contract.—In America, both North and South, many tunnels have been built, the modern ones being mostly driven since the introduction of railroads. Until the building of the Hoosac tunnel in Massachusetts, all tunnelling through rock in the United States was done by hand labor, by the methods above described. The project of tunnelling the Hoosac mountain was broached as early as 1825. In that year a board of commissioners, with Loammi Baldwin as engineer, was appointed to ascertain the practicability of making a canal from Boston to the Hudson, in the vicinity of the junction of the Erie canal with that river. Their report ("Massachusetts Commissioners' Report," 1826, p. 141) declares that "there was no hesitation in deciding in favor of the Deerfield and Hoosac river route," and that "there is no hesitation therefore in deciding in favor of a tunnel; but even if its expense should exceed the other mode of passing the mountain, a tunnel is preferable." Railways being shortly after introduced, the canal project was dropped. In 1828 surveys were made for three routes to afford Massachusetts railway connection with the west, viz., by Greenfield, by Northampton, and by Springfield. The last or southern route was chosen. The work was not begun immediately, but Massachusetts never lost sight of the advantage of a direct route to the Hudson river. This was finally accomplished in 1842, by the completion of the Western railroad to Albany. In 1848 application was made for a charter for a railroad from the terminus of the Vermont and Massachusetts line, at or near Greenfield, through the valley of the Deerfield and Hoosac, to the state line, there to unite with a railroad leading to Troy. The location was filed in the clerk's office of Franklin and Berkshire counties in November, 1850. In 1854 an act was passed "to enable the Troy and Greenfield railroad company to construct the Hoosac tunnel," by which the state, on certain conditions, lent its credit to the amount of $2,000,000. The estimated cost of the proposed double-track tunnel was $1,948,557, and of the road and equipment $1,401,443; total, $3,350,000. Still the company were unable to raise the funds necessary, in addition to the state loan. In 1855 a contract was made with E. W. Serrel and co., under which some work was done; and another was made with them in 1856 for the construction of the road and tunnel for $3,500,000, they subscribing $440,000. This contract also fell through, as did one made with H. Haupt and co. in the same year, by which the railroad company agreed to pay $3,880,000 for the completion of the road and tunnel. In 1858 a contract was again made with H. Haupt and co., by which the contractors themselves agreed "to assume the labor of collecting subscriptions and of carrying on and completing the Troy and Greenfield railroad and the Hoosac tunnel." Under this contract H. Haupt and co. were to receive $2,000,000 in bonds of the state of Massachusetts, to be exclusively appropriated to work done on the tunnel; $900,000 in mortgage bonds of the company; and $1,100,000 in cash, through cash subscriptions and capital stock of the company. Under this contract the work was vigorously prosecuted up to July, 1861, when, a difference arising between the contractors and the state engineer, a certificate for the amount claimed by the former on a payment was refused, and the work was thereupon abandoned by them. In 1862 an act passed the Massachusetts legislature, providing "for the more speedy completion of the Troy and Greenfield railroad and Hoosac tunnel." Under this act a board of commissioners was appointed to examine into the matter on the part of the state. At the request of these commissioners, the Troy and Greenfield railroad company, acting under the authority of certain provisions of the act, surrendered to the commonwealth of Massachusetts, under the several mortgages held by said commonwealth, the road and property of the company; such surrender having been authorized by the board of directors, by a vote passed on Aug. 18, 1862. This action was ratified by a vote of the stockholders, and on Sept. 4, 1862, the commissioners took possession of the road and its property. The commission after a full examination made a thorough report (dated Feb. 28, 1863), embracing the three following most valuable sub-reports: 1, a report of Charles E. Storrow on European tunnels; 2, a report by Benjamin H. Latrobe on the Hoosac tunnel; 3, a report by James Laurie on the Hoosac tunnel and the Troy and Greenfield railroad. In conclusion the commissioners recommended that the work should be undertaken by the commonwealth. At this point the cost and estimates were as follows:

Amount advanced by the state up to the date of the commission	$1,431,447
Estimated cost by the commission of completing the tunnel (double track)	3,218,323
Estimated cost of putting the road from Greenfield to the mountain in running order	652,060
Estimated cost of construction of two miles of road from western portal of tunnel to North Adams	67,500
Estimated additional cost of depot buildings, &c.	75,000
Estimated cost of rolling stock	275,000
Total estimated final cost of road and tunnel	$5,719,330

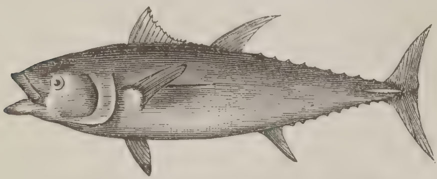
At this time, according to the report of James Laurie above noted, the condition of the work proper was as follows:

Whole length of the proposed tunnel, feet		24,416
Deduct portion already excavated at each end.	2,400	
Deduct portion between shaft and proposed western portal of tunnel	1,850—	4,250
Leaving to be excavated under the mountain		20,166

The shaft here referred to was on the western slope of the mountain, 325 ft. in depth. Mr. Laurie estimated that by sinking a central shaft about 1,000 ft. deep and working therefrom (which was afterward done) the tunnel, advancing at the rates respectively of 55 ft. a month from the two end portals, and 40 ft. each way from the shaft, would be completed in 11 years from date, *i. e.*, in 1874; this estimate being based on the supposition that the central shaft would reach bottom in four years from its commencement. Work was resumed on the tunnel under the auspices of the state in October, 1863, under the control of the same board of commissioners, who appointed Thomas Doane chief engineer in charge. The governor at the same time appointed Benjamin H. Latrobe of Baltimore state consulting engineer of Hoosac tunnel.—Mr. Laurie in his report to the commissioners says that shortly after the Troy and Greenfield railroad was chartered, the attention of inventors was turned to the subject of tunnelling machines. One was constructed at South Boston in 1851, especially for the Hoosac tunnel, which weighed about 70 tons, and was designed to cut out a groove around the circumference of the tunnel 13 in. wide and 24 ft. in diameter, by means of revolving cutters; the central core left was to be subsequently blasted out with gunpowder. It is reported to have cut, on a trial made March 16, 1853, on a vertical face of rock near the proposed entrance of the tunnel, at the rate of 16½ in. an hour, and under more favorable conditions at a previous trial 20 in. an hour. Various trials were made with this machine, the total distance cut by it amounting to about 10 ft., but it did not prove successful. A second machine constructed at Hartford, and known as the "Talbot tunnelling machine," also working on the principle of revolving cutters, and adapted to cut out a core 17 ft. in diameter, was tried about this time near Harlem, but proved a failure. A third machine was constructed in New York, adapted to cut a core of 8 ft.; this was adopted by Mr. Haupt during the continuance of his contract, in the early days of the tunnel, but also proved a failure. Experiments were instituted by Mr. Haupt himself, while engaged with his contract at Hoosac, toward the elaboration of a percussion drill; but in 1861 the termination of his contract for a time put an end to them. Afterward he again took up the subject, and in 1867 published a description of the Haupt drill. By the time this invention had been perfected, the Burleigh drills, which have since attained so great a reputation (see Blasting), had been adopted and were in full use at Hoosac. They were first tried in June, 1866, under the direction of the commissioners, and even in their crude and unimproved condition were favorably noticed in Chief Engineer Doane's report. In January, 1867, the office of chief engineer was abolished, and the engineer corps reduced to one resident engineer, W. P. Granger; Mr. Latrobe still supervising as consulting engineer. In October, 1867, owing to the accidental lighting of some naphtha at the central shaft, the head house, shaft buildings, &c., were consumed, and 13 lives were lost. Previous to this time portions of the work had been let out by contract, Messrs. Dull, Gowan, and White having the east and central shaft headings, through rock, and Mr. B. N. Farren the west end, through soft ground, including the arching of the same. Owing to the above mentioned accident, Messrs. Dull, Gowan, and White voluntarily surrendered their contract, received their pay, and abandoned the work, returning it to the hands of the commissioners. Benjamin D. Frost was appointed superintending engineer in May, 1868, and on Dec. 24 of that year a contract was effected between Messrs. Shanly brothers of Montreal and the commonwealth of Massachusetts for the final completion in full of Hoosac tunnel. The dimensions were to be: "in rock, unarched, 24 ft. wide and 20 ft. high, in the clear; where arching required, 26 ft. wide and 24½ ft. high (above the rail), in the clear." The prices bid in the contract varied in the different portions of the work, and also according to whether the work was "already begun," "to be finished," or for "extension of full-sized tunnel." The bids accepted for the latter item were as follows: east end section, per cubic yard, $11; central section from shaft, $14; west end section (part soft ground), $12; for arching part of the tunnel with brick, per thousand of bricks laid, $22. The total price agreed on for the work specified by the contract was $4,594,268, the whole to be done by March 1, 1874. At this time Mr. Latrobe resigned as consulting engineer; and that post, after the successive resignations of James Laurie and Edward S. Philbrick of Boston, is now (1876) held by Thomas Doane. The work was vigorously attacked by the Messrs. Shanly at all points. The Burleigh drills and compressors were used throughout their contract with excellent results. Under their patronage, the manufacture of nitro-glycerine (previously used in the tunnel) was carried on and improved by George M. Mowbray of North Adams. The east heading met the one driven east from the central shaft on Dec. 12, 1872; the west heading met the one driven west from the shaft on Nov. 27, 1873; the errors in alignment and levels were astonishingly small, especially as the former meeting was at a distance of 1,563 ft., the latter of 2,056 ft., from the shaft, down which the plumb lines had to be carried over 1,000 ft. The Messrs. Shanly concluded their contract and effected a final settlement Dec. 22, 1874. Independently of the contract taken by them, an agreement was entered into between the state and B. N. Farren, on Nov. 19, 1874, to do certain arching and enlarging at the eastern portal of the tunnel. By authority of an act passed by the legislature in 1874, a commission of experts, comprising Prof. T. Sterry Hunt of Boston and Prof. James Hall of Albany as geologists, and Thomas Doane, Josiah Brown, and Daniel L. Harris as civil engineers, was appointed to examine and report on the amount of arching that would be still necessary. Their reports are embodied in that of the commission of 1875, as is also a report from Edward S. Philbrick, consulting engineer, recommending an additional amount of 1,600 ft. of arching, besides that included in the Shanly contract. Work on this arching is still (March, 1876) in progress. Under a law of 1874 a board of corporators of the Boston, Hoosac Tunnel, and Western railroad was created, who reported that the tunnel had up to that time cost the state about $14,000,000. By a subsequent act of 1874 the corporators were superseded by five directors, to whom the interest of the state in the tunnel and railroad was transferred.—The next tunnel in the United States in which machine drills were introduced with effect, after their practicability had been demonstrated at Hoosac, was the Nesquehoning tunnel in Pennsylvania, constructed under the direction of J. Dutton Steele as chief engineer. (See paper by J. Dutton Steele in "Transactions of the American Society of Civil Engineers," 1871.) Here the Burleigh drill and ordinary black powder were used. The Musconetcong tunnel, on the Lehigh Valley railroad extension through New Jersey, was the next heavy piece of work in the eastern states on which machine drilling was adopted. This tunnel was begun in April, 1872, and finished in June, 1875, under the charge of Robert H. Sayre, chief engineer and general superintendent of the Lehigh Valley railroad company. Charles McFadden of Philadelphia took the contract, and completed what has been conceded to be one of the heaviest pieces of tunnel work ever attempted in America, and yet one of the most rapidly built. Every modern appliance was used. The Ingersoll drill was adopted, about 26 being kept on hand, and from 16 to 18 in constant use. Four Burleigh compressors supplied the air required at the west end, and four Rand and Waring compressors at the east. Dynamite was used throughout as an explosive, and gave entire satisfaction. Very heavy difficulties were encountered in the prosecution of the work, owing to the large bodies of water met with. The total length of the tunnel was a little less than one mile. It was begun by sinking a slope to grade on the western side of the mountain, about one third of the distance through, virtually dividing the tunnel into one third of soft ground working at the west, and two thirds of very hard ground at the east. The headings were started east and west from the bottom of this slope in November, 1872. The east heading had been started in July, 1872. Owing to the heavy cutting necessary at the west end, the heading could not be connected with those from the slope, and from a shaft subsequently sunk, until November, 1873. In May, 1873, so heavy a body of water was struck in the slope heading going east, that it could not be controlled. The miners were driven out, and the slope half filled. The water undermining the props and backing of the timbering in the slope, part of the roof fell in, and the work at that point had to be abandoned temporarily. A shaft was then sunk west of the slope, and headings were driven east and west to tap and draw off this water. Here again new and even heavier bodies of water were encountered, resulting in great expense and much loss of time. Finally the difficulties were overcome, the water tapped, and work resumed on the original slope heading going east, which met the east heading coming west in December, 1874, the errors in alignment and level being less than half an inch. (For further details on the construction of this tunnel see a paper by Henry S. Drinker in the "Transactions of the American Institute of Mining Engineers," vol. iii.) With the admirable and delicate instruments now so readily obtainable, it would require a positive effort of carelessness on the part of the engineer to entail any serious error in tunnel surveys. Especially noticeable among instruments are those recently perfected by Messrs. Heller and Bright-ly of Philadelphia, who have made a specialty of tunnel transits.—The above described three tunnels have been taken as particular examples, because they are the latest driven at the present time (March, 1876), and are the best examples of the present stage of the art of tunnelling in the United States. A large tunnel in Nevada, known as the Sutro tunnel, has been in process of construction with machinery for some years. (See NEVADA.) It is intended to serve as an adit to the Comstock lode. (See "Report of United States Sutro Tunnel Commission," Washington, Jan. 6, 1872.)—One of the first tunnels in the United States was on the Alleghany Portage railroad in Pennsylvania. It was built in 1831, double track, 900 ft. long; contract price, $1 47 per cubic yard; total cost, 14,857 cubic yards, $21,840. Another early work was the Black Rock tunnel, on the Reading railroad, built in 1836. This was 1,932 ft. long, and the excavation proper of the tunnel cost $125,935. According to data furnished by Mr. B. H. Latrobe of Baltimore, there are 44 tunnels on the line of the Baltimore and Ohio railroad and its branches, with an aggregate length of 37,861 ft., or 7 m. 901 ft., the tunnels varying from 80 to 4,100 ft. in length. The Sand Patch tunnel, on the Pittsburgh and Connellsville branch, was begun in 1854 and finished in 1871. The work during this time was intermitted for a total period of nine years, owing chiefly to the financial embarrassments of 1858. It was driven through the old red sandstone, and cost nearly $500,000. The Kingwood tunnel, 4,100 ft. long, was begun in September, 1849, and finished in May, 1852, at a total cost, including excavation and arching, of $724,000. The Broadtree tunnel, 2,350 ft. long, on the same road, begun in the spring of 1851, was completed in April, 1853, at a total cost (excavation and arching) of $503,000. The Chesapeake and Ohio railroad is 423 m. long, and has 7 m. of tunnelling; the Big Bend tunnel, on the Greenbrier division, is 6,400 ft. long. —Of the rates of progress attainable by machine drilling, a fair average can be deduced from three large tunnels driven through different kinds of rock. At the Hoosac tunnel, through mica schist and micaceous gneiss, with nitro-glycerine, the progress attained by Shanly brothers at the east end in 1869 averaged 139½ ft. a month, and in 1870, 126½ ft.; at the west end in 1870, 100¼ ft. In sinking the central shaft 1,080 ft. in depth, through rock, the average total progress per working month was 21 ft., but the 230 ft. sunk by Shanly brothers was driven in 7½ working months, or at the rate of 30·7 ft. a month. At Nesquehoning, through conglomerate, the average attained in 12 months' driving was 100 ft. a month; while through red shale an experience of two months gave an average of 160 ft. a month. Common black powder was used, the consumption in the conglomerate being about 6 lbs., and in red shale 3½ lbs. per cubic yard of rock broken. At the Musconetcong tunnel the average monthly advance through a very hard syenitic gneiss, pronounced harder by experts familiar with both than any body of rock met in the Hoosac tunnel, was in 1874: east heading, average of 12 months, 115·8 ft.; west heading, average of last 6½ months, when steady work was attained, 136·8 ft. At this tunnel a shaft was also driven 110 ft. in depth through soft ground, with timbering, at an average rate of 24¼ ft. a month. The prices bid at the present day for tunnel excavation vary from $4 to $7 and $8 per cubic yard. But the contract prices are not always a sure criterion as to the final cost; $6 per cubic yard is a medium bid. Very heavy and expensive tunnel work is often done in constructing underground railways through cities. In these the plan generally adopted is first to make an open-air excavation through the streets, then build the arches and fill in the ground again. A very heavy tunnel was lately finished under the London docks, passing also under some large warehouses, and needing very careful work. The quantity of water pumped was enormous. The final cost was at the rate of £390,000 a mile.—*Subaqueous Tunnels.* Among these should be particularly noted the first one built under the Thames at London. Except however in view of its vast expense, and the fact that it was the forerunner of modern subaqueous tunnelling, its record at the present day, since the system has been further developed, has no very practical interest. It was begun in 1807, intermitted, and resumed in 1825, under Sir M. I. Brunel, intermitted again, and at last completed and opened for foot passengers in 1843. Its total length is 1,200 ft.; final cost nearly £1,200 per lineal yard advanced. (See LONDON, vol. x., pp. 616–617.)—A tunnel that has attracted much attention throughout both Europe and this country is the one at Chicago, driven out under Lake Michigan, for the purpose of obtaining pure water for the city. This tunnel, begun in March, 1864, and completed in March, 1867, was entirely original in plan; the engineer was Mr. E. S. Chesbrough. A crib was first sunk in Lake Michigan, about two miles from the shore, 58 ft. in horizontal outside measurement on each of the five sides, and 40 ft. high. The inner portion or well has sides parallel with the outer ones, 22 ft. long each, leaving the distance between the inner and outer faces of the crib, or thickness of the breakwater, 25 ft. This breakwater was built on a flooring of 12-inch white pine timber, laid close together. The outer and inner vertical faces, and the middle wall between them, were all of solid 12-inch white pine timber, except the upper 10 ft. of the outside, which was of white oak, to withstand better the action of the ice. The outer and inner walls were strengthened and connected with brace walls and cross ties of 12-inch timbers, all securely bolted. The crib was built on land, launched, towed into place, filled with stone, and sunk. An iron cylinder, cast in 9-foot sections, of 9 ft. internal diameter and 2¼ in. thick, was then lowered within the crib to the bottom of the lake; and this cylinder was connected with the land two miles distant by a tunnel under the lake bottom. Gate wells were constructed in the sides of the crib, and after the completion of the tunnel the top section of the cylinder, extending above water level, was removed, and the water admitted through a screen. The tunnel, of circular cross section, was driven through a stiff blue clay; diameter of excavation 5 ft., subsequently lined with two rings of brick. The final cost in full to the city was $457,844. According to the statements and books of the contractors, the items were: crib and outer shaft, $117,500; land shaft, $12,000; tunnel proper, $195,000; total, $324,000. The balance of the expenditure was used in necessary contingencies. For full details of this work see "Eighth Annual Report of the Board of Public Works" (Chicago, 1869); also a report of Prof. W. P. Blake, commissioner of California to the Paris exposition (1867). A second tunnel, 7 ft. in diameter, extending to the same crib, was completed in July, 1874, at a total cost of $411,510; and two tunnels for traffic have been constructed under Chicago river. A tunnel under Lake Erie, at Cleveland, Ohio, begun in August, 1869, finished in March, 1874, is similar in plan, purpose, and construction to the one first driven under the lake at Chicago, except that much greater difficulties were encountered in its construction, from meeting several bodies of very soft ground. It is 6,606 ft. in length, and the total cost amounted to $320,352.—It was estimated by Capt. Tyler in 1873 that between 300,000 and 400,000 persons yearly crossed the English channel at Dover, that the number was constantly increasing, and that if a tunnel were built it would probably be doubled. The idea of a tunnel under the channel was first broached by M. Mathieu, a French engineer, who laid plans for one before Bonaparte in 1802. Owing to the subsequent disturbances the projector and his plans were lost sight of. Subsequently plans were proposed by M. Thomé de Gamond, Dr. Payerne, Messrs. Franchot and Tessier, Favre, Mayer, Dunn, Austin, Sankey, Boutet, Hawkins Simpson, Low, Boydon, Brunlees, Waenmaker, and others. To M. Thomé de Gamond is conceded the credit of pushing the project to its present advancement. In 1872 the present channel company was incorporated, Sir John Hawkshaw, Mr. James Brunlees, and M. Thomé de Gamond being appointed the engineers. The route finally adopted places the tunnel on a line drawn from St. Margaret's bay near the South Foreland, on the English side, to a point between Sangatte and Calais in France. The total proposed length of the tunnel is 31 m., of which 22 m. will be under the channel. Should the preliminary tests prove favorable, it is proposed to begin the actual construction by sinking shafts on either shore to the depth of 450 ft. below high-water mark. Driftways will be driven from the bottom of these for the drainage of the subsequent tunnel proper. The tunnel, if constructed, is to begin 200 ft. above the driftway, and will be driven from both ends. It is to be through the chalk, and in no part of it will there be less than 200 ft. of ground between the crown of the arch and the bed of the channel. It will be on a down grade of one foot in 80 to the junction of the drainage driftway, and then on an up grade of one in 2,640 to the middle of the strait. It is proposed to drive the driftway or heading with Dickinson Brunton's machine for tunnelling through chalk, which works like an auger boring wood. It is believed, from actual work done, that this machine will advance at the rate of from a yard to a yard and a quarter an hour. At this rate it would require two years to construct the driftway, driving from either end, at an estimated cost of £800,000. After the heading has been driven through, it has been estimated that four years' time and an outlay of £4,000,000 will finish the work, including arching; but Sir John Hawkshaw and his associates consider it best, before beginning the work, to double this figure as an estimate. The preliminary works to be undertaken are the sinking of two shafts at either extremity of the tunnel, from which an ordinary mining driftway is to be driven about half a mile out under the sea, the cost of which is estimated at £160,000. This done, the engineers will be better able to judge of the ultimate practicability of the work.—See *Lehrbuch der gesammten Tunnelbaukunst*, by F. Ržiha (6 vols., Berlin, 1865–'72); and *Der Tunnelbau*, by J. G. Schön (4to, Vienna, 1866). There is no complete work in English on modern tunnelling. The facts in this article are largely drawn from a practical treatise on American and European tunnelling, now (1876) in course of preparation by Henry S. Drinker, E. M., of Philadelphia.

TUNNY, a marine fish of the mackerel family, and genus *thynnus* (Cuv.). The body is elongated and compressed, with a slender tail keeled in the middle, and with two oblique cutaneous folds at the base of the caudal fin on each side; mouth large, with the teeth small, awl-shaped, in a single row on each jaw, and fine and crowded on the vomer and palate; there are two dorsals, near together, the posterior followed by nine or ten finlets opposite those of the anal fin; scales largest around the pectoral region, forming a kind of corslet, on the anterior part of the back, and along the lateral line; cerebellum remarkably large. The common tunny of Europe (*T. vulgaris*, Cuv.) attains a length of 15 to 20 ft., and a weight of more than 1,000 lbs.; it is dark blue above, the corslet lighter, sides of head white, and below grayish white spotted with silvery; first dorsal, pectorals, and ventrals black, the other fins mostly flesh-colored; the pectorals are scythe-shaped, and one fifth the length of the body.

It is very active and voracious, feeding on herring and the small migratory species. Tunnies are very abundant at the E. and W. ends of the Mediterranean, and in its narrowest portions generally, approaching the shores in summer in large shoals for the purpose of spawning; at this time they are captured in large nets arranged in a funnel-like form. The flesh is highly esteemed, almost like meat, as firm as that of the sturgeon, but finer flavored. It is found also in the Atlantic and in the North sea. The principal fishery of the present time is carried on in Sicily and Sardinia.—The American tunny (*T. secundo-dorsalis*, Storer), called also horse mackerel and albicore, attains a length of 9 to 12 ft.; it is nearly black above, silvery on the sides, and white below; gill covers and pectorals silvery gray; iris golden; ventrals black above and white below; finlets mostly yellow; the second dorsal is much higher than the first, anal further back than in the European tunny, and the pectorals are shorter. It is found from New York to Nova Scotia, coming into Massachusetts bay about the middle of June and remaining through September; it gets very fat by the end of August, and is then valuable for the oil, which is obtained by boiling the head and the abdomen; a single fish yields about 20 gallons; it is taken by the harpoon, and is active, strong, and tenacious of life; it feeds on menhaden and other small shoal fish; its flesh, which is rarely used here except for mackerel bait, resembles lean pork, with a fine mackerel taste.—The tunny of the tropics (*T. pelamys*, Cuv.), with other allied genera of the family, has been described under Bonito.



American Tunny (Thynnus secundo-dorsalis).

TUNSTALL, or **Tonstall, Cuthbert,** an English prelate, born at Hatchford, Yorkshire, in 1474 or 1475, died at Lambeth palace, Nov. 18, 1559. He was educated at Oxford and Cambridge, became a fellow of the latter university, and then studied at Padua. He became rector of Harrow-on-the-Hill in 1511, and in 1515 archdeacon of Chester. In 1516 he was appointed master of the rolls, and sent as commissioner to Brussels, where he concluded two treaties with Charles I. of Spain (afterward Charles V.), and became acquainted with Erasmus. In 1521 he was made dean of Salisbury, in 1522 bishop of London, and in 1523 lord privy seal; and he was twice ambassador to Spain and France. In 1530 he was translated to the bishopric of Durham. He soon after resigned the privy seal, but he remained bishop through all the changes made by Henry VIII. and Edward VI., and also had a place in the councils of state, till October, 1552, when he was deprived of his bishopric and committed to the tower. Mary reinstated him, but declining the oath of supremacy on Elizabeth's accession, he was again deprived in July, 1559, and remained the guest of Parker, archbishop of Canterbury, till his death. His works include *In Laudem Matrimonii* (4to, London, 1518); *De Arte Supputandi Libri IV.* (4to, 1522), a treatise on arithmetic, often reprinted; "Compendium and Synopsis," an abridgment of Aristotle's "Ethics" (8vo, Paris, 1554); "A Defence of Predestination" (4to, Antwerp, 1555); and a volume of prayers (8vo, 1558).

TUOLUMNE, an E. county of California, bounded N. by the Stanislaus river and E. by the Sierra Nevada mountains, and drained by the Tuolumne river; area, 1,944 sq. m.; pop. in 1870, 8,150, of whom 1,524 were Chinese. The surface is level in the W. part, and in the E. mountainous and covered with excellent timber, which is largely exported; the soil of the valleys is very fertile. It was formerly one of the most important mining counties of the state, and mining is still carried on to a considerable extent. The chief productions in 1870 were 21,920 bushels of wheat, 7,995 of barley, 5,260 of potatoes, 48,525 lbs. of wool, 26,760 of butter, 51,590 gallons of wine, and 5,132 tons of hay. There were 1,283 horses, 1,681 milch cows, 2,849 other cattle, 30,117 sheep, and 4,266 swine; 5 breweries, 5 saw mills, and 8 quartz mills. Capital, Sonora.

TUOMEY, Michael, an American geologist, born in Cork, Ireland, Sept. 29, 1805, died in Tuscaloosa, Ala., March 20, 1857. He early emigrated to the United States, and in 1835 graduated at the Rensselaer polytechnic institute, Troy, N. Y. In 1844 he was appointed state geologist of South Carolina, in 1847 professor of geology, mineralogy, and agricultural chemistry in the university of Alabama, and in 1848 state geologist. He published a "Report on the Geology of South Carolina" (4to, Columbia, 1848); "First Biennial Report on the Geology of Alabama" (8vo, Tuscaloosa, 1850); and, with Prof. F. S. Holmes, "Fossils of South Carolina" (4to, parts i.–x., Charleston, 1855–'7).

TUPELO, a name given by some tribes of Indians to species of *nyssa*, especially *N. multiflora;* this is also called sour gum and black gum, and is described, together with the characters of the genus, under the latter title. There is much confusion among the species, as they are very variable; there are at least four in the United States and one or two in the Himalaya mountains and other eastern localities. The one above referred to is the most common. The large or one-flowered tupelo (*N. uniflora*) is found from Virginia and Kentucky southward, often growing in the water; the bark is very corky, and the wood so light that sections of the branches and roots are used as floats for seines; its large leaves, 4 to 12 in. long, are often heart-shaped at base;

the fertile flowers are solitary; the blue fruit an inch or more long. A more southern species is the water tupelo (*N. aquatica*), which grows in the pine-barren swamps of North Carolina, and extends southward and westward; it occurs both as a mere shrub and as a large tree, with smaller leaves and fruit than those of the common *N. multiflora*, or black gum. A fourth species is known as the Ogeechee lime (*N. capitata*), a small tree found near the coast in Georgia and Florida; its sterile flowers are capitate, or in a head, and the solitary fertile ones are succeeded by a red fruit, an inch or more long, quite acid, but eatable, and in request for making preserves.

TUPÍ-GUARANÍS, a widely extended family of Indians in South America, embracing the Guaranís proper in Paraguay, among whom the Jesuits established their famous missions described by Muratori and Charlevoix; the eastern Guaranís or Tupís in Brazil, consisting of a vast number of tribes chiefly on the coast; the northern Guaranís, near the Orinoco; the central Guaranís or Chiriguanes, in the northern part of the Gran Chaco; and the Omaguas or western Guaranís, in the district of Quito. These last were numerous, warlike, and powerful, and were regarded by other tribes as a peculiarly noble race. They refused to receive missionaries, and at one time carried on a fierce war against the viceroy of Peru. The Tupís and Guaranís proper were mild and unwarlike, falling a prey to the cannibal Aymborés and to the Portuguese, who invaded their towns to reduce them to slavery. The Guaranís had not the conception of a Great Spirit common to the tribes in the northern part of the continent. They were never civilized except by the Jesuit system of reductions, in which they were kept in a kind of tutelage, or by their enrolment in the Brazilian army. In some respects they differed from other American tribes and resembled natives of the Pacific islands. The Mandrucús, a Guaraní tribe who fled northward from the Portuguese, build houses like the Dyaks, and like them dry and preserve the heads of their enemies; the blowpipe of the Amazon and of Borneo are the same; the Purupurús of the Amazon have the throwing stick of the Australians; while bamboo baskets and boxes from the Amazon can scarcely be distinguished from those of Borneo and Papua. During the flourishing period of the Paraguay missions in 1732, the Christian Guaranís numbered 144,000, but in 1742 they had lost 50,000 by European diseases. The Portuguese in 1750 claimed and obtained seven missions, which were at once abandoned by the Indians. The suppression of the Jesuits was a deathblow to the missions, and the Indians soon dwindled away. The Portuguese had from the first enslaved them, exterminating whole villages and compelling others to emigrate. The most remarkable exodus was that of the Tupinambas and Tamoyas, who under Jappy Assu emigrated from their southern homes and settled 3,000 m. off on the Amazon, where they are known as the Mandrucús. In all Brazil there are only 19,000 Indians reported at the present time. The Chiriguanes and Omaguas hold their own better, but have gradually disappeared from Colombia, Venezuela, and Ecuador.—The original seat of the Guaranís is in doubt; some think, from the higher character of the Omaguas and Chiriguanes, that they were the original stock, but their language is evidently but a dialect, less perfect in its structure and vocabulary than that of the Guaranís on the southeast. The beauty of this language is extolled by many investigators of American linguistics. The standard grammar and vocabulary of the Guaraní are the *Tesoro de la lengua Guaraní*, by Padre Antonio Ruiz de Montoya (Madrid, 1639), and *Arte y vocabulario*, by the same (1640). The *lingoa geral* of Brazil is based on the Tupí, a Guaraní dialect. As to it see *Diccionario da lingoa Tupy, chamada lingoa geral*, by Dias (Leipsic, 1858), and *Chrestomathia Linguæ Brazilicæ*, by Dr. Franco (Leipsic, 1859).

TUPPER, Martin Farquhar, an English author, born in London, July 17, 1810. He graduated at Oxford in 1832, and in 1835 was admitted to the bar, but has never practised. His "Proverbial Philosophy, a Book of Thoughts and Arguments originally treated" (1838; 2d series, 1842; 3d series, 1867), brought him into immediate popularity, and, in spite of much contemptuous criticism, has passed through numerous editions, and been translated into several languages. In 1845 he was elected a fellow of the royal society, and he has received the Prussian gold medal for science and art. His numerous succeeding works include "A Modern Pyramid to commemorate a Septuagint of Worthies" (1839), a series of sonnets and essays on 70 celebrated men and women; "An Author's Mind" (1841), containing plans of 30 unpublished works; "The Crock of Gold," "Heart, a Social Novel," and "Twins, a Domestic Novel" (1844); "Probabilities, an Aid to Faith" (1847); "Hactenus, a Budget of Lyrics" (1848); "Surrey, a Rapid Review of its Principal Persons and Places" (1849); "King Alfred's Poems in English Metre" (1850); "Farley Heath" (1851); "Hymns for all Nations, in Thirty Languages" (1851); "Ballads for the Times" (1851); "Heart, a Tale" (1853); "Probabilities" (1854); "Lyrics" (1855); "Stephen Langton" (1858); "Three Hundred Sonnets" (1860); "Rides and Reveries of Mr. Æsop Smith" (1861); "Cithara, a Volume of Lyrics" (1863); "Alfred," a play (1865); "Raleigh," a play (1866); "Our Canadian Dominion; Half a Dozen Ballads about a King for Canada," and "Twenty-one Protestant Ballads" (1868). In 1875 he wrote a play founded upon incidents of the American revolution, and introducing Washington and contemporary characters. In 1851 Mr. Tupper visited the United States. His life has been spent principally in retirement at his maternal estate, in the parish of Albury, near Guildford, Surrey.

TURANIAN RACE AND LANGUAGES. The constituent members of this race (whose ethnological appellation has been chosen in reference to the Turan of the Persians, the land of the northern nomads, in contradistinction to Iran) are as follows: 1. The Finno-Hungarian, Uralo-Finnic, or Ugrian branch. Its subdivisions are: *a*, the Ugric, including the Hungarian or Magyar as principal member, with the Vogul and Ugro-Ostiak in and beyond the Ural; *b*, the Bulgaric, including the Tcheremisses and Mordvins, scattered tribes along the Volga; *c*, the Permian group, of the Permian, Sirian, and Votiak, in eastern Russia; *d*, the Finnic or Tchudic, including the Lapp, the Finnish proper, or Suomian, and the Esthonian. The Bashkirs are also now considered as belonging to this branch. This is the most western branch of the family, lying chiefly within the limits of Europe; it is also the one of highest endowment, most perfect language, and most advanced culture. 2. The Samoyedic branch, comparatively insignificant in numbers, position, and history, and one of the lowest races of the Asiatic continent. The Samoyeds occupy principally the country between the Obi and the Yenisei, the inhospitable shores of the Arctic ocean from the White sea to beyond the North cape of Asia, and in small groups the northern mountains of central Asia. 3. The Turkish or Tartar (more properly Tatar) branch, the most widely spread of all, reaching from Turkey in Europe to beyond the middle of central Asia, with important outliers in the yet more remote northeast, as the Yakuts of the Lena. Its subdivisions are very numerous, but are grouped in three chief classes: those of the southeast, in and to the east of Turkistan; those of the north, including among others the Kirghiz and Yakuts; and those of the west, stretching from northern Persia through Asia Minor and the Crimea to Constantinople, and scattered in patches over the European dominions of the sultan. 4. The Mongolian branch, composed of three families, East Mongols, West Mongols, and Buriats, inhabiting the present territory of Mongolia, the slopes of the Altai mountains, and in groups the lands bordering on Persia, India, and China. 5. The Tungusian branch, of which the principal race is the Mantchoo, which has held China in subjection during the past two centuries. There is no question respecting the family relationship of these branches. The common name Turanian is more frequent than any other, but various scholars prefer the terms Mongolian (in the wider sense), Uralo-Altaic, Scythian, or Tartaric; the first of these four seems to be gaining universal favor. It has been sought to extend still further the boundaries of this immense family, by attaching to it the Dravidian races of southern India and other Asiatic peoples, and even tying on the Malays and Polynesians, and the North American tribes; but such sweepingly synthetic classification is, in the present stage of linguistic ethnology, to be regarded as utterly unscientific. Even the combination of the branches above mentioned into one family is not beyond question; the Mongol and Mantchoo branches may yet be found unconnected with the others.—As the Aryan or Indo-European languages are much more varied and diverse in their development than the Semitic, so they are, in their turn, vastly exceeded in this respect by the idioms now under consideration. The law of linguistic connection prevailing among the latter is quite peculiar; between tribes confessedly of near kin exist differences of linguistic material even in cardinal points, such as the pronouns, numerals, and important affixes of derivation. A marked similarity of linguistic method, however, runs through them all, and helps to stamp them as kindred. They are all formed on what is called the agglutinative type; that is to say, the root or theme everywhere maintains its form almost unchanged, and all formative syllables are suffixed, never prefixed, to it; and they enter with it into no intimate union giving rise to forms which are accepted by the mind, without analysis, as signs for the complex idea; they remain in the condition of loosely appended elements. There are no varieties and irregularities of nominal and verbal flexion; each language has but a single declension and (with unimportant exceptions) a single conjugation. The plural of declension is formed by a pluralizing particle, to which the same case endings are then attached as in the singular. Grammatical gender is unknown. The cases are numerous. Prepositions always follow the words they govern; as, indeed, it is a general rule that the governed word precedes the governing. Words connecting sentences, relatives and conjunctions, are in most languages hardly employed at all. A marked phonetic peculiarity running through all the dialects is the law of harmonic sequence of vowels; the vowels are divided into two classes, heavy and light (or hard and soft), and within the same word only heavy or only light vowels can follow one another; the vowel of a suffix, or those of a series of suffixes, changing to conform themselves to the character of that of the root. The languages are rich in harmonious and well developed vocabularies, so far as the sound goes, and they abound in nice distinctions of certain kinds. Yet their rank in the general scale of language is low; they are deficient in sharp distinction of the principal grammatical categories, and awkward, cumbrous, and incomplete in the expression of thought. This character belongs to them in varying degree; the Mantchoo dialects are the poorest of all, and the Mongol do not much surpass them; the Tartaric idioms hold the middle rank; the tongues of the Finnic branch, particularly the Finnish proper and the Hungarian, possess a marked superiority to the others. Most of the languages of the family are known only in their present condition. None of the branches has ever had a properly national literature, if we except the mythic and legendary songs of the Finns and the mostly lyric popular songs of the Hungarians; but even some of the remoter tribes, under the influence and by the aid of foreign teachers, have acquired the art of writing, and have brought forth religious and historical works, while the Hungarian and Turkish have developed important literatures. It is also believed that on the cuneiform monuments of Mesopotamia and Persia is represented, in the inscriptions of the third order, a Ugrian dialect, now frequently designated as Accadian, and that we have there authentic evidence and remains of an ancient Ugrian civilization, which preceded and formed the basis for that of the other races in the same regions. F. Lenormant has recently (1874) written a grammar of the Accadian on this assumption of its value. These results of a small number of investigators are not yet fully accepted by scholars in general.—See Rémusat, *Recherches sur les langues tartares* (Paris, 1820); Rask, in several of his philological works; Schott, in numerous memoirs published by the Berlin academy, especially *Ueber das altaische oder finnisch-tartarische Sprachengeschlecht* (1849); Castrén, in a series of grammars, essays, accounts of travel, &c. (St. Petersburg, 1853–'8); Max Müller, "Letter on the Turanian Languages," in Bunsen's "Philosophy of Universal History," vol. i., and "Lectures on the Science of Language" (London, 1861); and Pauly, *Description ethnographique des peuples de la Russie* (St. Petersburg, 1862).

TURBINE (Lat. *turbo*, a whirling, or that which whirls), a water wheel through which the water passes, guided by channels in the wheel itself, and usually by other passages exterior to the wheel which cause it to impinge on the wheel buckets at the proper angle to secure efficiency. The guide curves (as the walls of the last named channels are called) and the buckets of the wheels are usually both curved in such manner that the water shall enter the wheel as nearly as possible without shock, and shall leave it with the least possible velocity. Turbines are generally, but not always, set in the horizontal plane, their axes being vertical; their size diminishes as the height of fall increases, and for falls of ordinary height they are very much smaller than the ordinary forms of so-called "vertical" water wheels, an advantage which increases with the height of fall. Their smaller size gives necessarily a high velocity of rotation, which constitutes their most important advantage over the older forms of wheel; it permits the adoption of less heavy and expensive machinery for transmitting the power, dispenses with gearing, and gives greater regularity of speed and nearly equal efficiency under all heights of fall. The turbine was introduced into general use by Fourneyron in France in 1827, and soon after by Fairbairn in England and by Boyden in the United States. Turbines are classed as outward-flow, inward-flow, and parallel-flow wheels, according to the direction taken by the water in passing through them; but the principle already enunciated applies to all. Could the water be entered upon the wheel absolutely without shock, and discharged absolutely without velocity, the efficiency of the wheel would be perfect, and the energy of the fall would be all transformed into work. The efficiency of good turbines, under favorable circumstances, approaches 80 per cent., and has been known to exceed that figure; the usual value is about 75 per cent. The efficiency is determined as follows: The amount of water flowing through the wheel is ascertained by gauging; its weight, measured by the height of fall, indicates the maximum power of the stream, or the power available. The actual amount of power utilized by the wheel is determined by measurement with the dynamometer. If R = the resistance and v = the velocity with which the wheel overcomes that resistance, $R \times v$ = the work done in the unit of time, and $Rv = WhC$, in which expression W is the weight of water flowing per second, h the height of fall, and C the coefficient of efficiency, or that fraction of the total available fall which is actually utilized by the wheel; the value of C is the "modulus" of the wheel. This value is capable of being estimated with approximate accuracy by the designer of the wheel, and the performance thus predicted, by the use of formulas involving quantities dependent in magnitude upon the forms of the guiding channels. Turbines give the highest efficiency when their speed is between 0·5 and 0·7 of that due to the height of fall. The velocity of direct flow, or that with which the water passes through the wheel, is to be preserved as nearly uniform as possible, and the passages are to be given such form and magnitude of cross section as will insure that uniformity. The velocity of whirl is made as nearly as possible equal to the rotary velocity of the wheel, and the water is thus passed upon the wheel without shock. It should glide over the buckets without sudden change of velocity, and should finally pass out with a speed opposite in direction and equal in magnitude to that of the wheel, thus dropping out of the wheel with the least possible velocity of flow, and with its original *vis viva* transformed into mechanical energy. Fig. 1 is a vertical section exhibiting the construction of the Boyden outward-flow turbine, made by the Holyoke machine company. A is a quarter-turn leading the water smoothly upon the wheel; B is the lower curb; C the disk carrying the guides; D the wheel with its guide channels, shown with the guide curves more perfectly in the plan, fig. 2; E is a disk connecting the wheel to its vertical shaft; F, G, G′ are supporting beams; S the shaft; I the support for the bearings; J the driving gear; and R the apparatus for moving the gate. In the Boyden wheel is illustrated the outward-flow turbine. In the inward-flow wheel, the water enters between guide curves, or is carried in a spiral channel, and the form of the buckets of the wheel is modified in accordance with the principles already stated, and gives the form seen in plan in fig. 3, in which A is the wheel disk and B is the shaft. In the parallel-flow turbine the water enters upon the wheel as in fig. 4, which represents the Bodine turbine. It is cased in so that it may be set at any point in the fall, utilizing the so-called suction of that part below it, as well as the pressure due to the column above it, a method of arrangement first introduced by Henschel and Jonval. The wheel was invented by Fontaine. The upper set of guides are fixed; the lower set are the wheel buckets. In the Burnham turbine, fig. 5, the inward and downward flow forms are combined to make a wheel of very high efficiency, while yet cheap in construction and durable. In the Leffel wheel, fig. 6, the stream is divided to obtain the combined inward and downward flow and to secure greater effectiveness, and also to obtain more perfect regulation. This form has been extensively introduced in the United States, as has also the preceding. The same letters denote the same parts in each figure. The arrows indicate the direction of flow. In Schiele's inward-flow turbine the water divides on entering the wheel, a part passing out above, the remainder emerging below, the wheel disk. The Fourneyron out-

ward-flow and the Jonval parallel-flow turbines are most used in Europe. Regulation is effected by a vertically sliding gate (R, fig. 1), by a set of valves at the entrances to the wheel (figs. 4, 5, 6), or by varying the positions of the guide blades themselves. The most perfect method would be by varying the velocity ratio of the wheel and the driven mechanism. The loss of efficiency in reducing the power of the wheel by regulation is often serious. Rankine states this loss as follows:

Opening	1	$\frac{1}{2}$	$\frac{2}{5}$	$\frac{1}{5}$
Ratio of efficiency	1	$\frac{5}{6}$	$\frac{2}{3}$	$\frac{1}{2}$

Whitelaw's turbine is a simple form of wheel without guide blades. Barker's mill was a very rude apparatus consisting of a vertical spout surrounding the shaft and conducting the water to hollow horizontal arms, from the extremities of which it emerged tangentially to the orbit of the orifices. These wheels are usually known as reaction wheels; their efficiency is comparatively small.—See Francis, "Lowell Hydraulic Experiments" (Boston, 1855); Rankine, "Steam Engine and Prime Movers" (London, 1859); and Mahan, "Hydraulic Motors" (New York, 1873).

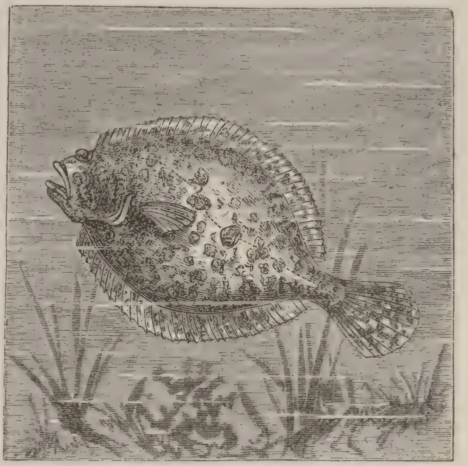
TURBOT, a marine, soft-rayed fish of the flatfish family, and genus *rhombus* (Cuv.), characterized by minute sharp teeth on the jaws and pharynx, the dorsal fin commencing on the head in front of the eyes, and like the anal extending to the tail, and the eyes on the left side. The European turbot (*R. maximus*, Cuv.), the finest of the family, sometimes measures 6 ft. in width, and weighs over 200 lbs.; the left side is brown and covered with small tubercles, and the right side or lower surface smooth and white; without the tail the body is nearly round; mouth large, opening obliquely upward; eyes in a vertical line, one over the other; gill openings large; pectorals small. It keeps on sandy grounds, and is a great wanderer, usually in companies, living near the bottom, and feeding on small fish, crustaceans, and mollusks; though voracious, it is particular in its choice of food, and will bite at none but fresh bait; the spawning season is about August, after which it soon recovers its good condition. Its flesh is white, fat, flaky, and delicate, and has been highly esteemed from remote antiquity; it is disputed whether this or the next species was the *rhombus* of the ancient Romans; the French call it water or sea pheasant on account of its fine flavor. Though not uncommon on the coasts of Great Britain, most of the turbot sold in the English markets are caught by Dutch fishermen on the long line of sandy banks between England and Holland. The fishery begins about the end of March and closes by the middle of August, and is prosecuted both by lines and trawl nets.—The brill, pearl, or smooth turbot (*R. vulgaris*, Cuv.) is a smaller and less delicate species, with smooth scales, from the same localities; the under jaw is the longer, and the upper eye a little behind the lower; it is reddish sandy brown, varied with darker, and sprinkled with white pearl-like specks; under surface smooth and white; it is found in the Mediterranean, as are several other species still less esteemed. —The American or spotted turbot (*R. maculatus*, Girard; *pleuronectes*, De Kay), called also New York plaice and watery flounder, is from 12 to 18 in. long, and 6 to 8 in. wide, sometimes attaining a weight of 20 lbs.; it is smooth, on the left side reddish gray with large circular or oblong darker blotches surrounded by a lighter margin, and with numerous white spots, especially on the fins; the lower surface white and spotless; iris silvery; gape wide, with a single row of separate, large, sharp teeth, and a protuberance on the chin; ends of dorsal rays free; body elongated; it resembles the brill more than any other Euro-



European Turbot (Rhombus maximus).

pean species. It occurs along the coast of the New England and middle states, and is a delicate article of food.

TURENNE, Henri de La Tour d'Auvergne, viscount de, a French soldier, born in Sedan, Sept. 11, 1611, killed near Sasbach, Germany, July 27, 1675. He was the second son of Henri de Bouillon, prince of Sedan, by Elizabeth of Nassau, daughter of William I. of Orange, and was sent when a boy to Holland to learn the art of war under his uncle Maurice. In 1630 he entered the service of France, received the command of an infantry regiment, distinguished himself in Lorraine under Marshal de La Force, became *maréchal de camp* in 1635, and served under La Valette in Germany, where he relieved Mentz, then besieged by the imperialists. In 1637, with an auxiliary corps, he joined the Swedish army under Duke Bernhard of Weimar, and captured several towns. In 1639, under the count d'Harcourt, he defeated the united Austrians and Spaniards at Casale, and in 1640 forced Turin to surrender. In 1642 he conquered Roussillon from Spain. After the accession of Louis XIV. he was made marshal of France, and placed in command of the army in Germany. He crossed the Rhine, worsted the Bavarians under Mercy, acted in concert with Condé in the three days' battle at Freiburg (1644), was defeated by Mercy at Mergentheim, May 5, 1645, but gained a victory over him in conjunction with Condé at Allersheim, near Nördlingen, three months later, and, joining the Swedish general Wrangel, conquered the Bavarians at Lauingen and Zusmarshausen, and forced the elector to sign an armistice in March, 1647. He then went to Flanders, and took several places, but was stopped in his career by the termination of the thirty years' war (1648). On his return to France, his love for the duchess de Longueville and his brother's example connected him with the Fronde. At the head of a Spanish army which was sent to support that movement, he was defeated near Rethel by Marshal Duplessis-Praslin, and driven out of France (1650). After vain efforts to reconcile France and Spain, he was permitted to return home, and henceforth proved the most loyal supporter of the king, while Condé became the leader of the Fronde. He defeated Condé's troops at Bléneau in April, 1652, followed him up to Paris, and inflicted upon him a severe loss in July in the faubourg St. Antoine, and thus secured the triumph of the royal cause. The Spaniards having invaded the north of France under Condé, he worsted them at Arras in 1654, gained the decisive victory of the "Dunes," June 14, 1658, and took Dunkirk. These successes hastened the peace of the Pyrenees, Nov. 7, 1659. In addition to his previous rank as minister of state, he now received that of marshal general. In 1667, war being declared against Spain, Turenne entered Flanders at the head of the army, accompanied by Louis XIV., and in less than four months conquered that province; and several of his conquests were confirmed by the treaty of Aix-la-Chapelle, May 2, 1668. In the war against Holland (1672) he commanded one of the invading armies; and when the European powers came to the rescue of the Dutch, he entered Germany, advanced to the Elbe, and forced the elector of Brandenburg to a separate peace in 1673; then, in a campaign celebrated for his skilful strategy, he protected Alsace from invasion (1674), crossed the Rhine at Philippsburg, routed the enemy at Sinsheim and Ladenburg, and drove them back to the Main, and devastated the Palatinate, burning 30 towns. In the following winter, with an army of scarcely 22,000 men, he nearly destroyed 60,000 Austrians and Brandenburgers under Bournonville, gaining victories at Mühlhausen (Dec. 29, 1674) and Türkheim (Jan. 5, 1675). He now wished to retire from active service; but he was the only French general capable of coping with Montecuculi. He therefore continued in command, and during four months the manœuvres and strategic operations of the two generals were subjects of universal admiration. Finally Turenne forced his rival into a position near Sasbach where he was constrained to fight at a disadvantage; the French commander consequently had a new victory in prospect, when, surveying the last preparations on the eve of the battle, he was killed by a stray ball, and his death caused his army to retreat beyond the Rhine. Turenne was originally a Protestant, but became a Catholic about 1668 through the influence of Bossuet.—See Ramsay's *Histoire de M. Turenne*, including his *Mémoires* of the campaigns of 1643–'59 (French and English, Paris and London, 2 vols., 1735; new French ed., 1838), and Neuber's *Turenne als Kriegstheoretiker und Feldherr* (Vienna, 1869).

TURF, The, a term signifying horse racing in all its forms, except the few trotting matches which are decided on turnpike roads in England. It was no doubt derived from the level ground and short close greensward of the heaths, downs, and commons upon which races were first run in England. These tracts had never been ploughed from time immemorial. The moist climate and strong soil kept the grass thick; and as the pasturage was free to all the inhabitants of the parish, it was of that close velvety texture upon which the horse likes to extend himself. Horse racing in Britain is of great antiquity, though racing at stated times and places cannot be traced beyond the reign of James I., who gave a Mr. Markham £500 for an Arab horse called the Markham Arabian, which being run against English race horses was easily defeated several times. This horse was believed to be the first pure Arabian imported into England. The consequence was that the old English race horse and the Turkish horses from the Levant, with barbs from Morocco and Andalusia, were preferred to the Arabians for some time. In the reign of Charles I.

a horseman named Place had a white horse which was known, and is still known in the stud books, as Place's White Turk. He had great merit as a stallion. When the Puritan sects prevailed, horse racing, in common with all other forms of popular amusement, was suppressed. But Cromwell took Place into his service, purchased his White Turk, and did all in his power to improve the breed of English horses. After Charles II. came to the throne, horse racing was revived all over the country. He imported four (or as some accounts say, six) mares from Tangier, and these have ever since been known as the Morocco or royal mares. Some of them enter into nearly all the old pedigrees. In the reign of Charles II. racing was again regularly established at Newmarket, where it has flourished ever since. During the short reign of James II. there is little to be said of the turf. In that of William and Mary it flourished greatly, and the first of the three great patriarchal imported sires became known in England. This was the Byerly Turk, a horse ridden by Capt. Byerly as a charger in William's army after James was expelled from the throne. This horse was first noticed in England in 1689. Where he came from nobody knows; but some of the best race horses and stallions that ever lived came from him. Jig was his son, and Partner his grandson; and King Herod, a horse to which we have been as much indebted as to Eclipse for the speed and bottom of our race horses for a century, was his descendant at four removes. A large number of Barbary and Turkish horses were also imported, one of the best of which was the Lister or Stradling Turk; and a gray Arabian called Bloody Buttocks, from a red mark on his haunch, was also of much merit. But the greatest of all the importations was in the reign of Queen Anne, when a Yorkshireman named Darley received from his brother in Palestine a bay Arab horse obtained from one of the desert tribes. This horse, afterward called the Darley Arabian, was the second and the greatest of the three sires from which the blood horse of modern times is mainly descended. From him starts the right male line of Eclipse and of Snap, and the King Herod line on the side of his dam. In 1715 the Darley Arabian got Flying Childers, the best horse by long odds that had ever run in England. The Darley Arabian also got Bartlett's Childers, who did not race himself, but was a famous stallion, great-grandsire of Eclipse on the male side, and sire of the Little Hartley mare, whose name appears in the pedigrees of many of the best horses of the present day. The Darley Arabian also got Snip, the sire of Snap, the latter a sire of such immense merit and enduring influence that he is third to King Herod and Eclipse. The racer was at first a cross-bred horse, composed of the old English breed and Spanish, Barb, Turk, and Arab strains, but improved by good feed and care and development on the turf. The Godolphin Arabian was the third of the three great foreign sires. It is now generally believed that he was a Barb instead of an Arabian. He was foaled about 1704, and sent as a present to Louis XIV. of France by the emperor of Morocco. He was deemed of little value in France, and was purchased by a Mr. Coke, who took him to England and sold him to one Williams, the keeper of a coffee house in London. This man gave him to Lord Godolphin, who bred many famous racers from him. The blood is nearly as much esteemed as that of the Darley Arabian, and perhaps more than that of the Byerly Turk.—It does not appear that any records were kept of the races even at Newmarket before the beginning of the 18th century. No horses ran until they were five years old, and the races were nearly all four miles or a greater distance. Basto, by the Byerly Turk, one of the very earliest of those whose exploits are recorded, was foaled in 1703. Bay Bolton was foaled in 1705. The first time of his running he won Queen Anne's gold cup at York for six-year-olds, four-mile heats, weights 168 lbs. Bay Bolton beat eight six-year-olds, giving them a year each. He was a successful stallion, and his daughter Gypsy was celebrated as a brood mare. Brocklesby Betty, a chestnut mare by the Curwen Bay Barb out of a little mare by the Lister Turk, was foaled in 1711. Before she was trained she had a foal, but she was the best race horse that appeared in England before Flying Childers. The latter, a chestnut horse with four white legs and a blaze in the face, was foaled in 1715, and was got by the Darley Arabian out of Betty Leedes. Flying Childers had immense speed and thorough bottom. He did not run much, for after he had shown his powers no one would start a horse against him. On one occasion, it is said, he ran over the Beacon course, 4 m. 1 fur. 138 yds., in 7 min. 30 sec. His stride was 25 ft. With his rider in the saddle, he leaped 30 ft. on level ground. He was a horse of fair size, and so was his brother Bartlett's Childers. After their time the thoroughbred horse increased much in height and length. Still some of the best and most enduring of that age were mere ponies. Gimcrack and Little Driver were only about 14 hands high. King Herod, a horse of fine size and power, was bred by the duke of Cumberland in 1758, and sold to Sir John Moore. He came in the male line of the Byerly Turk through Tartar, Partner, and Jig, and on the side of his dam he had two crosses of the Darley Arabian, one through Flying Childers and one through a daughter of the Arabian. King Herod had great speed and bottom. There have been better race horses, while it is agreed that there has been no better stallion. Between the time of Flying Childers and Eclipse 50 years elapsed, and many famous horses were produced, including Snap as well as King Herod. The former was son of Snip, whose sire was Flying Childers; and it is through the daughters of

Snap and the progeny of King Herod that we have so much of the invaluable blood of that famous horse at the present day. In 1764 another colt was bred by the duke of Cumberland, which proved a greater runner than any of its predecessors, and a larger horse. He was foaled during the great eclipse of the sun, and was called Eclipse. His sire, Marske, was a brown horse coming in the male line from the Darley Arabian through Bartlett's Childers; and his dam, Spiletta, was a granddaughter of the Godolphin Barb. Eclipse was the biggest, strongest, and greatest race horse that had ever run in England. He was 16 hands 2 in. high at the withers, one inch more at the croup, and his length was enormous. No such horse had ever been seen before. His temper was resolute and defiant. There was great trouble in breaking and riding him. No jockey ever dared strike him with the whip or prick him with the spur. He won eleven king's plates, most of them four-mile heats, weights 168 lbs. He double distanced a large field of good horses when his backer for a heavy bet undertook to place them. He was never defeated, and never paid a forfeit. Next to him the two best horses of his time were Goldfinder, son of Snap, and Shark, another son of Marske. The latter got big horses. Shark was himself 16 hands high, and was a great runner. He was afterward taken to the United States. In the 50 years between Flying Childers and Eclipse the race horse had increased about a hand in height, and when the latter retired from the turf in 1770, the thoroughbred, as a permanent and the most valuable variety of the horse, was established. There were now at the stud King Herod, Eclipse, and Snap, and from these three our best modern race horses are mostly descended. It would be difficult to find a race horse that has not the blood of two of them, and most of the best in England, America, and France take descent from all three.—When Eclipse retired, a great change in the management of the race horse was imminent. Up to that time few had run before they were five years old. Lord Grosvenor bred Pot-8-os from Eclipse and Sportsmistress in 1773. He ran him at three years old, and the colt won. At four he was beaten; but after he was five he never suffered defeat. He won over the Beacon course 20 times with high weights, and was the best son of Eclipse, though the latter had other sons of wonderful merit, such as King Fergus, Joe Andrews, Mercury, Dungannon, and Saltram. The whip, a challenge trophy still run for over the Beacon course, 140 lbs., and for 200 guineas, play or pay, whenever challenged for, had been established. Bay Malton had won it and held it. So had Mambrino, but he paid Shark 100 guineas to be allowed to keep it. In 1781 Lord Grosvenor challenged for it, and named Pot-8-os. It was delivered over. While Eclipse rejoiced in Pot-8-os, King Herod enjoyed equal glory through the wonderful success of his son Highflyer, foaled in 1784. He was bred by Sir Charles Bunbury, and sold to Lord Bolingbroke, and afterward to old Tattersall, the founder of the fortunes of that family. To Highflyer it is indebted for wealth and renown. His dam was Rachel, by Blank, son of the Godolphin Barb and the Little Hartley mare; and on the female side Rachel was a granddaughter of Regulus, son of the Godolphin Barb. Thus Rachel brought two crosses of the Godolphin Barb and one of the Darley Arabian to the cover of King Herod, who had himself two crosses of the Darley Arabian and one of the Byerly Turk. Highflyer ran at three years old. He won several times over the Beacon course, besides races at other places than Newmarket. He was never beaten, and never paid a forfeit. A hot discussion soon arose as to whether the descendants of King Herod or those of Eclipse were the best, and this lasted even after Hambletonian, grandson of Eclipse, beat Diamond, grandson of King Herod, in the great match over the Beacon course, by half a neck. The Diamond men wanted to run it again, but Sir Harry Vane Tempest would not consent, and Hambletonian never ran another race. The betting on this race was enormous. The war between the partisans of Eclipse and King Herod now waxed furious. The wise and impartial, however, determined to avail themselves of the blood of both these famous horses. Then began that curious and intricate crossing between the produce of King Herod and Eclipse and the daughters of Snap, which has ever since produced the horses of highest type in England, Ireland, America, and France. King Herod covered Lisette by Snap, and got Maria. This latter was bred to Pot-8-os, and the produce was Sir F. Poole's Waxy, a beautiful bay horse with one eye, great as a racer, and upon the whole greater than Highflyer himself as a sire. His favorite mate was Penelope by Trumpator. She was out of Prunella by Highflyer, and Prunella's dam was Promise, by Snap, the dam of Promise being a mare by Blank, son of the Godolphin and the Little Hartley mare. Whoever would understand what the turf means must acquire some knowledge of the true origin of the best families of the blood horse. Penelope had the Darley Arabian blood through Snap, grandson of Flying Childers, and through the Little Hartley mare, daughter of Bartlett's Childers. She also had two crosses of it through King Herod, and one more through Rachel by Blank, dam of Highflyer. She had the blood of the Godolphin Barb twice through his son Blank, and once through his son Regulus; and she had the blood of both these horses once more through her sire Trumpator. She had besides the blood of the Byerly Turk through King Herod once and through the dam of Trumpator once. Now, being put to Waxy, son of Pot-8-os by Eclipse and Maria, by King Herod, out of Lisette by Snap, Penelope produced for the duke of Grafton in six successive years, beginning with 1807, Whalebone, Web, Woful, Wilful, Wire, and Whisker. All these were great race horses, winners at four-mile heats with heavy weights. Whalebone, Woful, and Whisker were great stallions. Web and Wire were famous brood mares. The latter, after winning many races for the duke of Grafton in England, was sold by him to Mr. Bruen for 4,000 guineas. He took her to Ireland, where she won, the first season, the lord lieutenant's plate, four-mile heats on the Curragh of Kildare, 4,000 guineas in stakes, and 20,000 guineas in bets. From that time the Irish turfmen got hold of all the Waxy and Pot-8-os blood they could secure. They bought Waxy Pope, who was by Pot-8-os out of Prunella, and being unable to purchase either Whalebone or Whisker, they eagerly seized upon their best sons, Sir Hercules and Economist. The former got Irish Birdcatcher and Faugh-a-Ballagh, whose son Leamington is now highly prized here. Economist got Harkaway, and also the dam of the Baron, by Irish Birdcatcher. The Baron, thus in-bred to the brothers Whalebone and Whisker, struck the blood of their sister Web in Pocahontas by Glencoe, and from her produced Stockwell and Rataplan, two of the best horses that ever lived. This brings that line to our time, for Rataplan's daughter Mandragora is still producing, and is the best brood mare in the world. Her dam was Manganese, daughter of Irish Birdcatcher, Rataplan's grandsire. Mandragora belonged at the time of his death to the late Rev. Mr. King, vicar of Launde, for whom she bred Apology, winner of the Oaks and St. Leger in 1874. One other great line in which the blood of King Herod, Eclipse, and Snap is mingled, should be mentioned. Highflyer's best son was Sir Peter Teazle, whose dam was Papillon by Snap. Sir Peter, a splendid race horse, a great four-mile-heat winner, and a stallion whose excellence was only surpassed by that of Waxy, was owned by the earl of Derby. Papillon had the blood of both the Childerses, she had that of the Godolphin Barb, and also of the dam of the two True Blues, which mare was by the Byerly Turk. Out of Arethusa by Dungannon, son of Eclipse, Sir Peter Teazle got Walton in 1798, and Williamson's Ditto in 1799. From Walton and Parasol, by Pot-8-os, came Partisan, sire of Venison. The latter got Kingston, whose grandsons Kingfisher and Glenelg are among our young stallions in the United States. Partisan was also sire of Gladiator. Gladiator was sire of Queen Mary, dam of Balrownie, Bonnie Scotland, Blink Bonny, Caller Ou, &c. He was also sire of Miss Gladiator, dam of the great French race horse Gladiateur. Web, by Waxy, was grandam of Glencoe, the best horse that ever came to America. Being bred to Tramp, a horse closely descended from Eclipse in the male line, and from King Herod in the female line, Web produced Trampoline. Trampoline was bred to Sultan, a horse taking from Eclipse, King Herod, and Snap in several different lines, and she produced Glencoe. Glencoe was third in the Derby. He won the Goodwood cup and other races when three years old. When he was four, Lord Jersey challenged for the Whip and named him. But though he was only a colt and it was even weights, 140 lbs., Beacon course, nobody would run against him, and it was delivered over. Glencoe was foaled in 1831, at a time when the mischievous influences which have since affected the English turf and jeoparded the excellence of the blood horse had not obtained great sway. The running of two-year-olds, though common enough, was not the rule as it is now. The system of handicapping, by which in theory the worst horse in a race is put upon a level with the best and all the rest, through different weights, had then hardly begun. It has since attained huge dimensions, and there are now run in England at least ten times as many handicaps, generally over short distances, as of all other races put together. It is believed that this system, with its multitude of short dash races, has had a pernicious effect on the throughbred horse in respect of stamina. Handicapping afforded a chance for a middling horse to win much more money than the best of his time could, especially if the latter did not attain to his greatest excellence until he was four years old. It secured very large entries and big fields, and enabled professional betting men to extend their operations vastly. —Up to the time when Glencoe was on the turf, there were a great many local country meetings in various parts of England, especially in the midland counties, where fox hunting was most delighted in. At these races there were no very large prizes to bring the great horses from Newmarket, Epsom, and Yorkshire, and there were no railroads to afford them ready conveyance. The consequence was that the running horses were mostly those bred and kept in the neighborhood, and as a rule they were fast, stout, and honest horses. Many of the races were heats. The courses were chiefly staked out upon heaths, which were partly overgrown with gorse. There were no stands. The ladies viewed the races from carriages drawn up outside the foot people, who stood along the cords which roped in the home stretch. There were always a great number of mounted men. So popular were these gatherings that all the neighboring gentry, yeomen, farmers, and tradespeople made it a point to attend with their families. The country meetings have nearly all ceased, and few farmers now breed the blood horses which formerly ran at them. The great three-year-old race of England is the Derby, which was founded in 1780, and first won by Sir Charles Bunbury's Diomed, who was imported to the United States. He was the sire of Sir Archy here, first American ancestor in the male line of Timoleon, Boston, Lexington, and Monarchist. The Derby, a mile and a half, is run on Epsom downs, generally in the latter part of May. The Oaks, also a mile and a half, and run for at the same meeting, is for fillies only. It was founded the year before the Derby, and was first won by Bridget, daughter of King Herod. The Derby was called after the earl of Derby. The Oaks was named after a country seat in the neighborhood belonging to Gen. Burgoyne. The third of the great three-year-old races is the St. Leger, a mile and three quarters, run for at Doncaster in autumn. It was founded in 1778 and named after Col. St. Leger. Hollandoise, a mare by Matchem out of Virago by Snap, was the first winner. It was then two miles. Prior to the Derby and the Oaks, the Two Thousand Guineas and the One Thousand Guineas are run for at Newmarket. They are each a mile. The former is for three-year-olds and the latter for three-year-old fillies. Besides these there are sweepstakes for three-year-olds called Derbys at other places. The great cup races are at Ascot, Goodwood, and Doncaster. These are two miles and a half, weight for age, but winners of the Derby and Oaks are penalized, and at Goodwood there are so many penalties for winning horses, and allowances for poor ones, that it is practically a handicap. The fields are small for the cups, for many people do not know what to do with a grand classical trophy of silver, about three feet high, even if they could win it. The royal plates are still run for. They are now commonly from two to three miles, and very few enter. The other cup races are mostly handicaps. The handicap races, from the Great Metropolitan, Goodwood stakes, Cesarewitch, Chester cup, &c., which are all two miles or more, range down to half a mile, and there are immense numbers of them. Those which are only a mile or less than a mile vastly outnumber those in excess of it. Over 2,000 race horses ran in England in 1875.—The thoroughbred horse of England and America is practically identical in breed, and in all probability there is no difference in quality where the treatment while young and the training and riding are the same. The noted training families, such as the Dawsons and Days, have been at it in England for about a century, and son succeeds father in the profession. The most successful breeder in America, for the number of mares he has kept, is John M. Clay of Kentucky, and he was always noted as the most generous and careful of feeders. He had much success with Magnolia and Topaz, daughters of Glencoe, and with Balloon, daughter of Yorkshire, and he preferred Lexington to all other stallions. His father, the great Henry Clay, established him as a breeder in some sort by making him a present of imported Yorkshire, a very fine race horse and excellent stallion. Nothing in this country ever surpassed the cross between Lexington and the daughters of Glencoe. It produced Kentucky, Norfolk, and Asteroid, all in one year; and more recently it was represented by Monarchist, a magnificent race horse. In the male line Glencoe is now represented here chiefly by Virgil, son of Vandal. But upon his daughters his towering fame chiefly rests. The progeny of his English daughter, Pocahontas, are numbered by hundreds, perhaps thousands, and their fame is world-wide. The greatest breeding establishments in this country are those of Mr. Alexander and Mr. Sanford in Kentucky. At the latter there are 5 stallions and 75 brood mares. Mr. Grinstead and Mr. McGrath are also eminent breeders in Kentucky. Capt. Cottrell of Mobile breeds largely. Near New York there are the large and well appointed breeding establishments of Mr. Belmont, Mr. Cameron, Mr. Withers, Mr. Welch, Mr. P. Lorillard, Col. McDaniels, and Mr. Morris. At the great establishments the produce are mostly sold when yearlings. Mr. Backman, Mr. Robert Bonner, Col. Russell of Boston, and many other gentlemen breed trotting horses.—The race courses of England are all greensward, and few of them are quite flat. In this country they are of dirt and generally flat. The usual shape is two straight parallel stretches of a quarter of a mile each, with curves at the ends a quarter of a mile in radius. Some are faster than others, a condition largely depending upon the soil; loam is the best. When dry and moderately hard on the surface, with a damp subsoil, the track is fast. The harder the track, the faster it is, provided it is not hard enough to make the horse sore and unwilling to extend himself. A soft track to train on and a hard one to run or trot on conduces to speed. Sand is slow. The Saratoga course is the fastest in the country, and that of Jerome Park, New York, is one of the slowest. The best four-mile performances have been by Lexington, 7 min. 19¾ sec., at New Orleans; Lecompte, 7 min. 26 sec., at the same place; Idlewild, daughter of Lexington, 7 min. 26¼ sec., at Centreville course, Long Island, with 14 lbs. more weight than her sire and Lecompte carried; Fellowcraft, son of Australian and Idlewild's sister, 7 min. 19½ sec., at Saratoga; and Wildidle, son of Australian and Idlewild, 7 min. 25½ sec., at San Francisco. Among the best horses of the last 15 years have been Lightning, Daniel Boone, Planet, Albino, Idlewild, Jerome Edgar, Blackbird, Thunder, Norfolk, Kentucky, Asteroid, Harry of the West, Longfellow, Kingfisher, Harry Bassett, Monarchist, True Blue, Tom Bowling, Wanderer, Springbok, Preakness, and Foster. The last two are very tough veterans. They are both by Lexington, both out of daughters of Yorkshire, and their grandams were both imported mares. Out of those mentioned 15 were got by Lexington, who died in 1875. As a stallion his value was enormous, and he succeeded best with mares having much English blood, such as the daughters of Glencoe, Yorkshire, Albion, Leviathan, &c.—*Steeple-Chasing.* About 1830 annual steeple chases were organized in the vale of Aylesbury and at St. Albans. The distance was commonly four miles as the crow flies. The men might get to the goal any way they could, provided their horses brought in their proper weight, and that they never went a hundred yards at one time along any road, lane, or highway, nor opened any gate or wicket. The courses were nearly straight, but a rider might diverge within certain limits marked by flags. Few could see the steeple chase from end to end. At that time the vale of Aylesbury was chiefly rich pasture land. The sod was old, and very tough in winter and early spring, the season for the steeple chases. There were no stone walls, and very few post-and-rail fences. The fields were enclosed by ditches and double hedges, called bullfinches and ox fences, because capable of confining oxen in their pasture. The hedges were chiefly composed of the hawthorn, blackthorn, and crab apple, together with wild roses and a great variety of briers. When in leaf such a fence could not be seen through, but in winter the young growth of the top, though wide, was neither very thick nor interlaced. No horse could go through such a fence without jumping more than breast high, and no horse that ever lived could clear the bullfinches by going clean over them. But good horses and resolute men could clear the old, stubborn part of the hedges, and go through the top-hamper bodily. The ditches were no impediment. The horse rising to the leap did so before he neared the ditch on the taking-off side, and if he got through the hedge he was pretty sure to clear the ditch on the far side. But the vale was intersected by wide and deep brooks. The natural brook flowing through a meadow and nearly full to its bare banks is much more formidable to the steeple chaser than the artificial brook with a fence on the taking-off side. Horses will jump a fence and brook readily enough, though they may know by experience that the water is beyond the fence; but many will refuse at naked water, especially when it glistens in the sunshine. The weights at Aylesbury, St. Albans, and other places were at first 168 lbs. It was the custom to choose a stiff four miles for the chase, that is, a line in which the fences were difficult, and the brooks wide and deep. Handicapping was introduced, to stop the further winning of two famous horses, Lottery and Gaylad, who took all the best prizes for several years. It was begun at Newport-Pagnell, but Lottery won with 180 lbs., and Gaylad was second. As soon as the handicap system was established, reports became rife about pullings. The steeple-chase course was mostly out of sight of the stewards, and a rider could pull his horse without fear of being detected. This, in part, brought about the modern system of round courses, over which the horses generally go twice and are in sight nearly all the way. So popular was steeple-chasing that those who could provide the land and construct the fences and stands were well repaid by fees and rentals when the spectators had a chance to see the chase. But the fences and brooks were artificial, and much less difficult than those of the real cross-country lines. The consequence was that a slighter and lighter sort of horse was trained to the business. The most famous of the old steeple-chasers ranged from about three quarters or seven eighths blood to quite thoroughbred. A large number of steeple-chase courses now exist in England, but not one of the old straight lines across the country is used. The chief of all is the Grand National Liverpool steeple chase. The course is about four miles and a half. The fences are fair. Beecher's brook (so called from Capt. Beecher, a noted steeple-chase rider) is 18 ft. wide, with a fence on the taking-off side from 3 ft. 8 in. to 4 ft. high. Most of the artificial water jumps in England are from 14 to 18 ft. wide. The weights range from about 175 lbs. to 140 lbs., and neither the high weights nor the low weights often win. The good steeple-chaser always takes his jumps in stride, and rushes at them rather than pauses. Chandler jumped 39 ft. over water, and 34 ft. has been cleared over hurdles. Steeple-chasing is very popular in Ireland, and the Irish horses have a cat-like aptitude for jumping. There were in England and Ireland, in the season commencing late in the autumn of 1874 and ending in the early summer of 1875, about 400 steeple chases, exclusive of those for only trifling stakes. During the same time the hurdle races were more numerous. In these the race is run over the flat course, but with hurdles about 4 ft. 8 in. high, placed an eighth of a mile apart. The thoroughbred steeple-chaser is entered at hurdles first, and if he turns out to be a good, bold jumper, is practised at hedges, rails, &c., and last of all at water jumps. The steeple chases in this country are too confined and twist about too much to give either horses or riders a good chance. The jumps, such as they are, come too frequently. Half the number would be better.—*Trotting.* This is almost wholly confined to the United States and Canada. It consists of races in which the horses are required to trot, and if they break into a gallop the riders or drivers are commanded by the rules to pull them to a trot as soon as possible. Yet considerable running is done sometimes. Nowhere else has the trotting horse attained anything like the speed which has been displayed in America. Nothing has been systematically done for the trotter in Europe, except in Russia, where Count Orloff established a breed which still has fine action and a good deal of speed. The old roadster could not go faster than a rate of about 12 m. an hour, but he could go a long way. The modern, high-bred and highly educated trotter is capable of going a mile at the rate of 25 m. an hour, and better. The great factor in the improvement of the trotter has been the trotting turf. The trotter, like the thoroughbred of early times, was a cross-bred horse, and his development here and in Canada began very early in the history of the colonies. The people of the northern states and of Canada were led to prefer driving to riding. The roads in summer and autumn were comparatively good. In winter the deep snows made sleighing rapid and easy, and a man who would have been frozen on horseback could travel comfortably in a sleigh. In the southern states the case was different. Maryland, Virginia, and the Carolinas produced blood horses, but no trotters. The fact that the early home of the fast trotter was the northern states and Canada shows that his excellence is the result of long use, and the inclination for that gait is now become partly hereditary. When the people of New York, New England, and Canada were driving rapidly and merrily to the music of the sleigh bells, and their horses were compelled to bend the knee to get over the snow among the pines, they were creating the possibility of future Flora Temples and Dexters. The best mares were selected to breed from, and the best stallion in the neighborhood was chosen for them. Races for small sums were made upon the road or upon the ice, and finally trotting tracks were established at such places as Boston, New York, and Philadelphia. Some of the best trotting mares were bred to the sons and grandsons of imported Messenger, and the strains of other blood horses in this country and Canada were also infused. The Arabian horse also entered into the composition of the trotter. The form best adapted for speed in horses was thus approached, and the nervous organization and clear wind which enable the horse to stay over a long distance of ground were acquired. Upon the nervous organization depends the great difference often found to exist between horses equally well bred and apparently equally well shaped. In the early days of the trotting turf most of the races were under the saddle. There were also many of two-, three-, and four-mile heats. After some time races in harness became more frequent, and those of three- and four-mile heats less so. The sulkies and skeleton wagons employed in the races were improved in construction and made lighter and truer. The tracks were laid out upon proper principles, and better cared for. The horses, regularly trained, and with the improved vehicles and tracks, displayed more and more speed, until Flora Temple finally beat 2 min. 20 sec. in harness. Even after that time races of two-mile heats and wagon races were common; but they have now almost wholly ceased. Associations make all the races mile heats, three in five, in harness. About the last of the great two-mile-heat races and wagon races were those in which Dexter defeated Lady Thorn in 1866. It is to be regretted that all the trotting races should now be of one pattern. People have largely lost sight of the main things involved in the issue of a race, and care only for time by the watch, which is in truth the least important element in the matter. Some horses have beaten the best time made by other horses with whom they would have stood very little chance in a race together. The time test does more than justice to the horse tried by it, and less than justice to the horses of past years. All the improvements in tracks, vehicles, and mode of handling go to the aid of the latest comer. There is hardly a track in the country now so slow as that of Buffalo was when Dexter made his best recorded time, or so slow as the Fashion course was when he made his faster actual time. The new courses are very much faster, though they are of the right length measured three feet from the pole. The best recorded time for a mile in harness is now 2 min. 14 sec. made in a trial for time by Goldsmith Maid, in which she had no opponent. The fast trotter is not usually as tall as the running race horse, and many of the best have been rather under-sized. Flora Temple was not much more than 14 hands high; Ethan Allen is not 15; Goldsmith Maid is 15 and half an inch; Dexter is 15 and an inch. But George M. Patchen and Lady Thorn were 16 hands high, and Gloster, a famous fast horse that died in 1874 at San Francisco, was nearly 17 hands high. The Orloff trotter of Russia was a cross-bred horse when Count Orloff first exhibited him. It is believed to be now established as a breed, measurably capable of reproducing without reverting to the peculiar points of the original ancestors. The count at first made use of Arabian horses and of mares from Norway and Holland. The trotting habit was no doubt inherited from the mares, and improved by training. Afterward another Arab cross was employed, and one with the English thoroughbred horse. The speed of some of the Orloff trotters is good, and from their pictures they must possess a large amount of good blood.

TURGENEFF. I. Alexei, a Russian historian, born in 1785, died in Moscow in December, 1845. He was early engaged in collecting materials in foreign countries relating to the ancient history of Russia, and his researches resulted in the publication of *Historiæ Russiæ Monumenta*, under the auspices of an archæological government commission (2 vols., St. Petersburg, 1841–'2; supplement, 1848). His letters to his brother were published in Leipsic (1872.) **II. Nikolai**, a Russian author, brother of the preceding, born in 1790, died in Paris in November, 1871. He studied in Göttingen, and after being employed in the civil service at St. Petersburg he was appointed in 1813 Russian commissary, in conjunction with the Prussian statesman Baron Stein, in provisional charge of the German provinces recovered from France. After returning to Russia he rose to be deputy secretary of the interior and agriculture, and became much interested in the emancipation of the serfs. This involved him in the revolutionary outbreak of 1825, and he was sentenced to death, but escaped to Paris, where he spent the rest of his life. He wrote *La Russie et les Russes* (3 vols., Paris, 1847).

TURGENEFF, Ivan, a Russian novelist, born in Orel in November, 1818. He studied in Moscow, St. Petersburg, and Berlin, and in 1843 received a clerkship in the ministry of the interior. He was subsequently banished to the provinces on account of his liberal sentiments, and after several years was allowed to return to the capital; but he has since chiefly resided in Paris and Baden. He first made himself known by several works of poetry (1843–'4), but achieved much greater success by his "Memoirs of a Sportsman," an exquisite humorous picture of Russian rural life (2 vols., 1852), and subsequently by his "Fathers and Sons" (1862), "Smoke" (1867), and other novels. Most of his works, some of which he wrote in French, have been translated into English, German, and other languages. Among them are "Liza," "On the Eve," "Dmitri Rudin," "Journal of a Useless Man," and "A Lear of the Steppe."

TURGOT, Anne Robert Jacques, baron de l'Aulne, a French statesman, born in Paris, May 10, 1727, died there, March 20, 1781. He was educated for the church, and in 1749 became prior of the Sorbonne; but he abandoned the profession in 1752, studied law, and in 1753 became councillor in the parliament and master of requests. As early as 1745 he had published his *Lettre sur le papier-monnaie*, and he now applied himself to the study of natural philosophy, agriculture, manufactures, and commerce, publishing his views in papers in the *Encyclopédie* or in pamphlets. The most remarkable of these are his *Lettres sur la tolérance* (1753). In 1761 he was appointed intendant of Limousin, and introduced many reforms in the administration of that province; free transport was allowed to corn and breadstuffs, taxes were lessened, roads and highways improved, and workhouses and charitable institutions established. In 1771 appeared his *Réflexions sur la formation et la distribution des richesses*, his chief work on political economy. He also published papers on loans and on mines, and *Lettres sur la liberté du commerce des grains.* On the accession of Louis XVI. he was made comptroller general of finances, and undertook to improve the financial condition of the kingdom by freedom of labor at home and of trade abroad, and by substituting for taxes on a multitude of articles a single tax on land. These reforms were encouraged by the king, but were obnoxious to courtiers and many others. In 1775 he was charged with having caused scarcity by his regulations respecting the grain trade. In January, 1776, he caused an edict to be issued, abolishing compulsory labor for the state, internal duties on breadstuffs, the privileges of trading corporations, &c. But this only increased the number of his enemies; the privileged classes were so loud in their complaints that the king was afraid to support his minister, and Turgot was dismissed in May. His *Œuvres complètes*, published by Dupont de Nemours (9 vols. 8vo, Paris, 1808–'11), were reprinted under the supervision of Eugène Daire and Hippolyte Dusard (2 vols., 1843–'4). His biography was written by Condorcet (London, 1786).

TURIN (It. *Torino*). **I.** A N. W. province of Italy, in Piedmont, bounded W. by France; area, 4,068 sq. m.; pop. in 1872, 972,986. It is watered by the Po and its numerous affluents. The eastern and southern portions of the surface are level or hilly; the northern and western are traversed by lofty branches of the Pennine, Graian, and Cottian Alps, containing many glaciers. Among the principal products are wheat, maize, mulberries, melons, and hemp; in the valleys rice and silk culture, and in the mountains cattle raising and mining, are extensive. The province is divided into the districts of Turin, Pinerolo, Susa, Aosta, and Ivrea. **II.** A city, capital of the province, in a large plain enclosed by the Alps excepting on the northeast, at the junction of the Dora Riparia with the Po, 77 m. S. W. of Milan; pop. in 1872, 212,644. It is remarkable for its fine bridges, that on the Dora forming a single arch, large squares and broad streets, the monuments and palaces in the new town, and its delightful promenades bordered by villas. Of the ancient walls, only the Porta Palatina and one or two other parts are now standing. The piazza Castello contains many public buildings, and is surrounded by palaces which extend along the via del Po to the collina di Torino, a pretty range of adjacent hills. The royal palace, on the N. side

Porta Palatina.

of this square, is remarkable chiefly for its size, and for its large library and interesting armory. In the centre of the square is the old palace of the early dukes of Savoy, restored in 1718 for the mother of Victor Amadeus II. and since called palazzo Madama. On the N. W. tower of the palace is the royal observatory. Adjoining the same square are the military academy and the theatre. The piazza di San Carlo is almost surrounded by arcades. The oldest church is the cathedral, the finest is that of San Filippo. A Protestant church was opened in 1853. The academy of sciences contains the *pinacoteca* or royal picture gallery, with celebrated paintings, and the museums of antiquity and natural history. The university, founded early in the 15th century and reorganized in the 17th, has a magnificent building with a library of 200,000 volumes, increased in 1875 by Cavour's library, bequeathed to it by the marquis Ainardo Cavour. He also left 3,000,000 lire in real estate for the charity hospital, one of the largest of the numerous charitable institutions. A fine *campo santo* was opened in 1829. Despite the variable and occasionally rough climate, the mortality has lately averaged only 27·2 in 1,000, smaller than in other large towns of Italy. The chief export is silk. The principal manufactures are silk goods, jewelry, furniture, pianofortes, and carriages.—Turin was originally settled by the Ligurian tribe of the Taurini, whence the name. It was conquered by Hannibal, and under Augustus became a Roman colony under the name of Augusta Taurinorum. In the 6th century it was the capital of a Lombard duchy; in the 8th Charlemagne made it the capital of the marquisate of Susa; and in the 11th century it became that of the house of Savoy. The French held the city at various periods, but their army under La Feuillade and Marsin was signally defeated here by the imperialists under Prince Eugene, Sept. 7, 1706. They occupied it in December, 1798, and Suvaroff in May, 1799; and the French again held it from 1800 to 1814, when it was restored to the Savoy dynasty. It was the capital of the kingdom of Sardinia till 1860, and subsequently of Italy till May, 1865.

TURKEY (*meleagris*, Linn.), a well known gallinaceous bird, the type of the family *meleagridæ*, of the group *alecteromorphæ* of Huxley. The bill is moderate and strong, shorter than the head, compressed on the sides, with culmen arched, and upper mandible overhanging the lower; the cere is elongated into a loose, pendulous, round, fleshy caruncle; head and upper neck bare, with only a few scattered hairs, and carunculated; base of lower mandible sometimes wattled; a tuft of long, black bristles on the breast, largest in the males; wing short and rounded, the first four quills graduated, and the fifth and sixth the longest; tail broad and rounded, pendent during repose, but capable of being raised and extended like a fan; tarsi robust, longer than middle toe, covered in front with broad, divided scales, and armed with a short obtuse spur; anterior toes united at base by a membrane, the inner the shortest, the posterior moderate and elevated; claws short and slightly curved. All the species in the wild state are indigenous to North America. The common wild turkey (*M. gallopavo*, Linn.) is about 3½ ft. long and 5 ft. in extent of wings, weighing from 15 to 20 lbs.; the naked skin of the head and neck is livid blue, and the excrescences purplish red; the general color is copper bronze, with green and metallic reflections, each feather with a velvet-black margin; quills brown, closely barred with white; tail feathers chestnut, narrowly barred with black, and the tip with a very wide subterminal black bar; the female is smaller and less brilliant, without spurs, often without bristles on the breast, and with a smaller fleshy process above the base of the bill. It has a crop and gizzard, and an intestine four times the length of the body; the cartilaginous tissue of the stomach is less hard than that of the common fowl. The full plumage is attained at the third year; the females usually weigh about 9 lbs. They fly in flocks of many hundreds, frequenting woods by day, feeding on acorns, all kinds of grain, buds, berries, fruits, nuts, grass, insects, and even young frogs; they make considerable journeys in search of food, flying and swimming across rivers a mile wide; though their flight is heavy, they are able to reach with ease the tops of the highest trees; they are so strong as not to be easily held when slightly wounded; they perch at night on trees. Quitting the woods in September, they come into the more open and cultivated districts, where they are killed in great numbers; they were formerly abundant in the middle, southern, and western states, but are now rare except in thinly settled regions, and have never been found west of the Rocky mountains. Although the turkey was exclusively an inhabitant of North America in its wild state, the earlier naturalists supposed it to be a native of Africa and the East Indies, and its common name is said to have arisen from the belief that it originated in Turkey; it was carried to England in the early part of the 16th century by William Strickland, lieutenant to Sebastian Cabot. Since that time it has been acclimated in most parts of the world, but the

Wild Turkey (Meleagris gallopavo).

(Boundaries of 1878)

domestic bird, contrary to the usual rule, has degenerated in size, flavor, and beauty. The flesh of the wild turkey is more pheasant-like than that of the domesticated varieties. The old males keep by themselves, as do the females and young, the former being apt to destroy the eggs in order to prolong the honeymoon; they are polygamous, the males in the breeding season, in March, strutting before the females, with tail spread and elevated, wings drooping, feathers ruffled, head and neck drawn back, emitting a puffing sound; the males also utter singular notes, resembling the word "gobble" several times repeated; they fight desperately for the possession of the females. The nest is a slight hollow in the ground filled with withered leaves, in a dry and sheltered situation, and usually contains, when full, 10 to 15 eggs; after this time the males conceal themselves while recovering their condition; the females alone incubate, carefully concealing the nest, approaching it with great caution and always in a different way, covering the eggs with dry leaves when going in search of food, and bravely defending them against depredators; sometimes three or four females lay in one nest, one remaining to guard it while the others seek for food. The males are attentive to the young, which run as soon as hatched, but are very tender and easily killed by cold and wet. Turkeys run very fast, and when pursued trust more to their legs than to their wings for escape; they are generally shot from their roosts at night, or entrapped in a pen or enclosure into which they are enticed by grain; their feathers are employed by the Indians in ornamental work; their greatest enemies are lynxes and owls, and other carnivorous mammals and birds.—Two other species of turkey, the *M. ocellata* (Cuv.) and *M. Mexicana* (Gould), have been described as inhabiting Central America, Mexico, and the table lands of the Rocky mountains, both closely resembling in plumage and habits the common wild species.—The progenitor of the present race of domesticated turkeys is not known with certainty; some naturalists incline to the belief that it is the *M. gallopavo*, while others consider it to be an allied species, perhaps now extinct. Domesticated turkeys thrive best on high, dry, and sandy soil, and when grasshoppers are plentiful can pick up their own living; in temperate climates they generally lay twice a year, 15 eggs or less, white with small spots of reddish yellow. One male will suffice for 12 to 15 females, the latter being prolific for about five years, though those of two or three years are the best hatchers; incubation lasts 27 or 28 days, and they are such close sitters that food must be placed within their reach; when they are raised on a large scale they are made to hatch in darkened places, and so that the turkey pouts, or young turkeys, shall all come out together; the young require warmth, proper food, and pure water, and must be protected against rain and the hot sun; they are liable at all ages to many diseases, for the treatment of which special works in abundance can be consulted.—Several fossil turkeys have been described by Professors Cope and Marsh in the post-tertiary.

TURKEY, or The Ottoman Empire (Turk. *Osmanli Vilayeti*), a country extending over parts of southeastern Europe, western Asia, and northern Africa. It consists of the absolute possessions of the sultan (Turkey proper) and of his dependencies, the latter embracing the tributary states of Roumania, Servia, Samos, and Egypt, and the nominal dependencies Tripoli, Tunis, and Montenegro. Turkey proper, usually divided into Turkey in Europe (situated between lat. 34° 45′ and 45° 30′ N., and lon. 15° 40′ and 29° 40′ E.) and Turkey in Asia (between lat. 12° 40′ and 42° 5′ N., and lon. 24° 50′ and 51° E.), borders on Austria, Servia, Roumania, European Russia, the Black sea, Russia in Asia, Persia, the Persian gulf, Arabia, the Red sea, Egypt, the Mediterranean, the Archipelago, Greece, the Ionian sea, the Adriatic, and Montenegro. Its political divisions (mostly vilayets) in Europe are the metropolitan district of Constantinople, Edirneh or Adrianople (Roumelia or Thrace), the principality of Tuna or the Danube (Bulgaria), Salonica (Macedonia), Janina (Thessaly and Albania), Prisrend (Albania), Scutari (formerly part of Prisrend), Bosnia (including Turkish Croatia), Herzegovina (until lately part of Bosnia), and Candia or Crete. The divisions of Turkey proper in Asia are the Asiatic portion of the metropolitan district, Khodavendighiar or Brusa, Aidin, Konieh, Angora, Kastamuni, Trebizond, Sivas, and Adana, all in Asia Minor; Erzerum (Armenia), Diarbekir (Kurdistan), Bagdad (Irak Arabi), Aleppo (N. Syria), Sur or Syria (central Syria, Phœnicia, and Palestine), Hedjaz and Yemen (in W. Arabia), Hedjer (in E. Arabia), and the islands of the White sea (Archipelago). The aggregate area of Turkey proper in Europe is about 140,000 sq. m., and in Asia 760,000 sq. m. The population of the former is about 8,500,000, and of the latter 13,200,000. The aggregate area of the dependencies is estimated at about 1,300,000 sq. m., and their aggregate population at about 26,000,000; but all statistics relating to Turkey are necessarily imperfect in the absence of regular official returns. The most important cities in Turkey proper, besides Constantinople, the capital, are Adrianople and Salonica in Europe, and Smyrna, Damascus, Bagdad, Beyrout, Aleppo, Brusa, Erzerum, and Trebizond, in Asia.—The coasts of Turkey proper are washed by the Black sea, the Bosporus, the sea of Marmora, the Dardanelles, the Archipelago, the Mediterranean, the Ionian sea, the Adriatic, the Red sea, and the Persian gulf. This vast extent of coast embraces many excellent harbors. It is indented by numerous gulfs and bays, of which some of the principal are the gulfs of Avlona, Arta, and Salonica, in Europe; Adramyti, Smyrna, Adalia, and Iskanderun, in Asia. Large salt lakes abound, chiefly in Asiatic Turkey, the most remarkable being the Dead sea in Palestine and Lake Van in Armenia. The rivers of Turkey in Europe may be classed under three heads: those flowing respectively into the Adriatic and Ionian seas, into the Archipelago, and into the Black sea. The first class are usually small, rising near the coast range of mountains; the Narenta, Drin, and Voyutza are the principal. To the second class belong the Salembria, Vardar, Struma, Kara-su, and Maritza; to the third, the Danube with its tributaries and a few small rivers. The rivers of Asiatic Turkey include those flowing into the Black sea, the Archipelago, the Mediterranean, the Red sea, and the Persian gulf, and the Jordan, which empties into the Dead sea. The principal rivers flowing into the Black sea are the Tchoruk, Yeshil Irmak, Kizil Irmak, and Sakaria. Those discharging into the Archipelago or the Mediterranean are small, but of historical interest, as the Menderes (Mæander), Tersus (Cydnus), Aasy (Orontes), and Litany (Leontes). The streams falling into the Red sea are insignificant, but among those flowing into the Persian gulf are the Euphrates and Tigris with their numerous tributaries. Turkey proper includes Thasos, Scio (Chios), Samos, and other islands of the Archipelago and sea of Marmora, as well as Candia, Rhodes, and Cyprus.—The two principal mountain ranges in European Turkey proper, which form the great watersheds between the different basins of the country, are: 1. The Illyrico-Hellenic or western range, comprising the Dinaric Alps, a continuation of the Julian Alps, which separate the Adriatic coast from the basin of the Save, and the Pindic chain, connected on the north with the preceding, separating Albania from Macedonia and Thessaly, uniting with the Olympian chain on the south, and forming the watershed between the Ionian and Ægean seas; Mt. Ida in Candia is considered an isolated branch of the southern continuation of this chain. 2. The Balkan or Hæmus range, branching off from the preceding N. E. of Albania, dividing Macedonia and Thrace from Bulgaria, and terminating in Cape Emineh on the Black sea. Its most important branch is the Despoto Dagh. (See BALKAN.) Others connect it with the S. E. Carpathians, which separate the tributary state of Roumania from the Austro-Hungarian monarchy. The mountain system of Asiatic Turkey is composed of the Taurus and Anti-Taurus ranges and their Armenian continuations, which form the connecting link between the Balkan system and the mountain systems of Syria, Caucasia, and Persia; and the Syrian range, extending southward from the Taurus, culminating in the Lebanon mountains, and terminating in the Sinaitic peninsula, on the shore of the Red sea.—The surface of European Turkey is undulating or mountainous, but with a large proportion of arable land of moderate elevation. Much of Asiatic Turkey consists of elevated plateaus, many of them scantily watered, while other regions once very fertile are now covered by the sands of the desert. The plains, which embrace the once wonderfully fertile tracts of Babylonia and almost all Mesopotamia, generally suffer from want of irrigation; and though the slopes of the mountains afford good pasturage, the raids of Bedouins and Kurds diminish the production. In European Turkey about 40 per cent. of the area is arable and vine land, 6 per cent. meadows, 11 per cent. grass land, 14 per cent. forests, and 29 per cent. unproductive soil. Turkey in Europe is subject to violent climatic changes. Owing to the elevation of considerable portions and to the cold N. E. winds from the interior of Russia, the winter is in many parts excessively cold. Albania, being sheltered from the N. E. winds by mountains, has a more uniform climate, but is subject to scorching heats, protracted droughts, and earthquakes. In Asiatic Turkey (outside the Arabian districts), the winter is cold and humid in the mountainous regions, but in the sheltered valleys and plains it is warm and delightful. The summer heats are excessive, especially in Asia Minor and Syria. The valley of the Jordan and the regions of the Euphrates and Tigris are intolerably hot and dry in summer. Little or no rain falls from April to the middle of September, but the night dews are heavy. The peaks of Mt. Ararat and of the higher summits of the Lebanon and Taurus ranges are covered with perpetual snow.—The principal mineral productions of European Turkey are iron in great abundance, argentiferous galena, copper, sulphur, salt, and alum. In Asiatic Turkey, there are copper, lead, alum, silver, emery, and rock salt, in Armenia; in Asia Minor, all these and considerable quantities of nitre; in Syria, iron and coal, and west of the Jordan indurated chalk. Much emery is produced, and exported from Smyrna, but the mineral resources of Asiatic Turkey are in general undeveloped.—The chief botanical characteristic of both European and Asiatic Turkey is the predominance of the *labiatæ*, *caryophyllaceæ*, and *ericaceæ* or heaths, of coniferous evergreens, and of the amentaceous trees common to the south of Europe. In the basin of the Danube the pine, beech, oak, lime, and ash are the principal forest trees, and the apple, pear, cherry, and apricot the most common fruit trees. In the provinces S. of the Balkan these trees are only found on the slopes of the mountains, while on the lower lands the palm, maple, almond, sycamore, walnut, chestnut, and carob trees, and the box, myrtle, laurel, and other evergreens, are found; in Bosnia are large forests of fir and pine; the maritime plains of Albania are favorable to the growth of the olive, orange, citron, vine, peach, plum, and other fruit trees; and the plain of Adrianople and most of the region S. of the Balkan abound in roses, from which the attar is largely distilled. Maize is cultiva-

UNIVERSITY OF ILLINOIS

ted in the south, rice, cotton, rye, and barley in the central provinces, and wheat, barley, and millet in the north. Though producing forest trees of the same families with those of European Turkey, the predominant trees of Asiatic Turkey are of different genera. The cedar, cypress, and evergreen oak crown the lower summits and thrive on the slopes of the Lebanon and Taurus; the sycamore and mulberry occupy the lower hills, and the olive, fig, citron, orange, pomegranate, and vine flourish luxuriantly in the lowlands. Mesopotamia abounds in dates, and in wheat, barley, rice, maize, tobacco, hemp, flax, and cotton.—Among wild animals of European Turkey are the wild boar, bear, badger, marten, wolf, wild dog, fox, civet, wild cat, bat, squirrel, beaver, hedgehog, mole, hare, fallow deer, roe, and chamois. Of birds there are over 250 species, including about 100 songsters. Game is plentiful, especially in the mountains. Fish are numerous, embracing all the known species of the Mediterranean; tunny, coral, and sponge fisheries are extensive; trout and other fish abound in the rivers, and leeches in the marshes. In Asiatic Turkey, the lion is still found E. of the Euphrates; the striped hyæna, lynx, panther, wild boar, and wild ass occur in Mesopotamia; the bear, wolf, wild hog, and jackal in Asia Minor; the leopard, hedgehog, jerboa, wolf, hare, and mole throughout Syria; and the Syrian bear on Mt. Lebanon. The camel, horses of the best breeds, the ass, ox, sheep, and goats, including the celebrated Angora species, are numerous. There are few countries for which nature has done as much as for Turkey; few in which the resources are so little developed; and, considering that the territories of the empire embrace those of ancient Assyria, Babylonia, Palestine, Phœnicia, Lydia, Ionia, &c., hardly any in which successive wars and misrule have destroyed so much of the results of former activity, wealth, and magnificence. For fuller descriptions see the articles on the separate parts of the empire (Albania, Armenia, Asia Minor, Bosnia, Bulgaria, Candia, Cyprus, &c.), and on its principal mountain ranges, rivers, and cities.—The races of Turkey are divided approximately as follows:

RACES.	In Europe.	In Asia.
Turks proper or Osmanlis	2,200,000	8,620,000
Turkomans, chiefly in N. Mesopotamia	....	100,000
Greeks	1,000,000	1,000,000
Armenians	60.000	2,000,000
Slavs (half Bulgarians, half Serbs)	3,550 000	....
Roumans or Wallachs	200.000	....
Albanians or Arnauts	1,200,000	....
Arabs	....	1,000,000
Syrians and Chaldeans	....	200,000
Druses	....	80,000
Kurds	....	100,000
Gypsies	200.000	....
Jews	70,000	80,000
Tartars	20,000	20,000
Total	8,500,000	13,200,000

The state religion is Mohammedan, and the alleged sayings and opinions of the prophet, and the decisions of his immediate successors comprised in the code of laws (*Multeka*), are binding upon the sultan. The laws and regulations (*Kannon Nameh*) established in the 16th century by Solyman the Magnificent constituted for a long period the basis of the administration of government and justice, and are still revered. But the Koran alone is the supreme authority in religion, law, and all spheres of government and life. It allows four wives, in addition to whom the sultan and other persons of rank and wealth may have unlimited numbers of concubines and female attendants or slaves. The masses of the poor can hardly support more than one wife, and even among the higher classes polygamy does not generally prevail. The rigid confinement of the females in the harem is in accordance with the Koran, which enjoins seclusion and modesty, and the veiling of the face. The ladies of the higher classes are averse to these restrictions, and are lightly veiled; but the masses of the orthodox Turkish women, especially in the interior, wear thick veils and reveal only the eyes. The Turks proper or Osmanlis, the Turkomans, Arabs, and Tartars are wholly, and the Kurds mostly Mohammedans; and a small portion of the Slavic race are of the same religion. The Mohammedans constitute a vast majority in Asiatic Turkey, but are a minority in every European vilayet except Prisrend and Scutari and the metropolitan district. The sultan is regarded as the successor of the prophet, and on that account as the head of all believers. Even rulers of remote Mohammedan communities have at various times recognized the sultan as the chief of all Mussulmans and invoked his protection. As the Koran constitutes both a code of law, of religion, and of ethics, there is a close connection between the ministers of religion and the interpreters of jurisprudence (muftis, mollahs, &c.). Together these form the body of the ulema (see ULEMA), governed by the sheikh ul-Islam, the only dignitary who holds office for life. The Christians of Turkey belong mostly to the Greek church, including about 6,000,000 members, mostly subject to the patriarch of Constantinople. The Armenian church is confined to the Armenian race. The head of the Gregorian Armenians is the patriarch in the Turkish capital, who ranks below the catholicos in Russian Armenia, but is otherwise entirely independent of him. A portion of the Greeks and Armenians, Nestorians, and Jacobites have united with the Roman Catholic church, but keep up separate organizations as united Greeks, united Bulgarians, united Armenians, Chaldeans, united Syrians, and Maronites. The number of Roman Catholics, inclusive of the members of the oriental churches who recognize the supremacy of the pope, is estimated at about 300,000 in European and from 300,000 to 400,000 in Asiatic Turkey. All these denominations, as well as the Protestants (whose converts are chiefly won from the Armenians by American missionaries) and the Jews, are recognized by the sultan as independent religious communities, with the privilege of maintaining their own ecclesiastical organizations. Among the numerous peculiar sects are the Druses and Ansaries in Syria. The antagonism between the various religious bodies is stronger in Turkey than anywhere else, and they are far from observing toward each other the tolerance which is granted to them by the government. A new educational law promulgated in 1869 provided for the establishment of elementary schools for both sexes in every commune, of schools of a higher grade and gymnasiums or colleges in larger towns, of industrial and normal schools, and of a university, after German models, which was opened in Constantinople in February, 1870. There have since been established there a school of law, a military school, one for engineers, and one of artillery, and a naval school on the island of Khalki in the sea of Marmora. The government has declared its intention to make the schools more and more national, and to abolish the old Arabian system of instruction. Outside of the capital the progress of education is slow, chiefly owing to the innate aversion of the Turkish mind for mental effort. The government, however, seeks to promote national literature, and recently passed a copyright law. The Christian communities strive to emulate European systems of education, especially the Greeks and the Protestants, and there are several good Catholic schools; but the most efficient institutions are the Robert college (American) at Constantinople, the new Protestant college at Beyrout, and the schools of the Prussian deaconesses in various places. —The empire abounds in archæological treasures. The most important results have been achieved in the present century by the excavations in Assyria, Asia Minor, Palestine, and Cyprus.—Turkey contains a number of foreign (called Frank) or extra-territorial communities, placed under the protection of resident diplomatic and consular agents. They originated in the Levant trading companies, many of the early English, French, Italian, German, and other settlers and adventurers becoming permanent residents; and their numbers have been greatly increased by the rapid progress of European monopolies in railways, finance, trade, and industry, and in all Turkish enterprises. The representation of foreign powers in Turkey dates from the 16th century, and has been protected by the so-called "capitulations" and subsequent treaty stipulations, affording full safety to diplomatic and consular officers, and vesting them with judicial powers and every right necessary to the interests of their constituencies. These include the richest Greek and English merchants, whose influence is almost boundless through their ambassadors and consuls. The native Christian subjects are called rayahs, and, whether Greeks or Slavs, chiefly belong to the Greek church, of the principal branch of which the czar is the supreme head, whence results the great influence of Russia. The social equality which prevails among the Mussulmans enables persons of the lowest condition to rise to the highest; but the rayahs have had no such opportunities, and, in addition to their hard struggles for subsistence, they have borne the brunt of Moslem fanaticism since the conquest of Constantinople, when the most influential Greeks (Fanariotes) made themselves serviceable to their conquerors, while the masses of the Christians were regarded as outlaws. Shut out from all contact with European civilization, they lost their mental energy and ambition, and became infected with Asiatic vices without acquiring the redeeming qualities of independence possessed by their conquerors, toward whom their outward obsequiousness and secret hatred increased in the measure of their helplessness and demoralization. The church became, under these circumstances, not only the idol of their faith, but also the only hope of their ultimate redemption through the influence of Christian nations. This abnormal condition of the rayah populations has more than once called for the intervention of foreign powers, while remaining a chronic source of disaffection and disturbance. The successive concessions which they received during the present century, under the pressure of disastrous events, have not materially lessened their burdens, although they now apparently enjoy equality before the law under the jurisdiction of mixed courts. They are also exceptionally admitted to official positions, and the latest decrees of the sultan remove all previous disabilities in this regard. But the Mohammedans respect no laws excepting those sanctioned by the Koran, and the officers charged with the execution of imperial decrees are generally opposed to the boons they are intended to confer on Christians. Many of the Turkish officeholders are also notorious for venality and incapacity, especially in remote provinces, beyond the immediate control of the vigilant foreign ambassadors at the capital. The Armenian rayahs have greater ethnological affinities with the Turks than the Greeks and Slavs. Many of them prosper in official positions in the capital, and as dragomans of foreign embassies, for which they are specially qualified by their adroitness in managing the pashas and their linguistic attainments. They are also clever financiers, and in that department eclipse both Greeks and Jews. But in Armenia proper their condition is made so deplorable by the Turkish officials and by the fearful ravages of the Kurds, that hundreds of Armenians have lately embraced Mohammedanism as the only alternative against these persecutions. The great Greek merchants are not rayahs, but protected foreigners. The Jews are mostly poor. They are descendants of refugees from Spanish persecution, retain a Spanish dialect, and are obliged to wear a distinctive costume, excepting a few whose wealth secures them special privileges. They are despised by the Turks and periodically persecuted by the Greeks. The Turks fully respect only foreigners invested with official rank or with powerful protection. In the absence of such prestige, the slightest provocation is apt to reveal their innate prejudices against the *giaour*, though, when not under the influence of fanatical or criminal passion, they are remarkable for their dignity and courtesy, and for honesty in their private relations.—The Turkish government, or Sublime Porte, is an absolute monarchy, the rule of which is vested in a sultan (officially called *padishah*, supreme ruler) of the dynasty of Othman. The sultan is allowed to govern in the most arbitrary manner, except in matters of religion and law, which require the concurrence of the sheikh ul-Islam (grand mufti). The succession to the throne has from the first been vested in the oldest surviving male member of the ruling family. The late sultan, Abdul-Aziz, wished to secure the throne to his eldest son Yusuf, making the succession direct from father to son, a change which was established in Egypt in 1866; but he encountered an invincible opposition to any deviation from the ancient rule, and was succeeded by the heir apparent, his nephew Mehemet Murad (born in 1840), the eldest son of the sultan Abdul-Medjid. Former sultans have frequently secured the succession to their sons by putting to death immediately on their accession all their other male relatives. The civil list of Abdul-Aziz was raised from £900,000 in 1868 to £1,200,000 in 1873, and he annually received besides £500,000 for pensions and charities, derived an additional revenue from crown domains and from presents, and might at his pleasure raise unlimited amounts. His actual annual expenditure was estimated at £4,500,000. This extravagance in the midst of national insolvency and peril shook even the loyalty of the orthodox Moslem, especially as the people were everywhere ground down by tithes and by the rapacity of tax-gatherers and other officials.—The empire is divided into vilayets, under governors general (*valis*). They are subdivided into sanjaks (districts) under governors (*mutessarifs*), and these into cazas (circles) under lieutenant governors (*kaimakams*), and the latter into nahiyes (communes). The mayors of villages are called *mukhtars*. The former eyalets or pashalics have been united or changed into vilayets. The provincial governors, who generally hold the rank of pasha, formerly had the right of sentencing persons to death; this has been withdrawn, but they still rule arbitrarily, particularly in remote districts, and are frequently in collision with the rayahs and the protected foreigners. Even after their proven dishonesty or unfitness, they are generally not dismissed from the service, but only transferred to a less important office. New territorial divisions are often created merely in order to make places for influential pashas.—The grand vizier presides over the council of ministers. This comprises the grand vizier's councillor, who acts as minister of the interior, the president of the supreme council of justice, who acts as minister of justice, and the ministers of foreign affairs, war, finance, navy, commerce, police, public works and quarantines, education, and archives, the superintendent of mosque property, and the president of the council of state established in 1868. The department of taxes, the united postal and telegraph services, and the mining department are respectively in charge of directors general. The ministerial council corresponds to the European cabinets, while the new council of state is intended for the preliminary discussion of new laws and public measures. This body comprises an executive department, and four others, devoted to finance, justice, education, and commerce, and consists of 50 Mohammedan and Christian members chosen by the sultan. A scheme for the reorganization of the police and of the collectors of taxes, the latter to supersede the policemen (*zaptiehs*), was in 1876 in process of adoption. In 1868 a supreme court for civil and criminal cases was substituted for the former grand council of justice, and the office of attorney general was created early in 1876. There are courts of appeal in the capital of each vilayet, and various superior tribunals exist all over the country, about 100 subordinate tribunals, and mixed courts for settling cases between Mohammedans and non-Mohammedans, besides the consular courts. This divided jurisdiction naturally results in complications. The ancient "capitulations" relating to foreign jurisdiction were recently abolished in Egypt as altogether obsolete, and they have been modified in Turkey proper, but without satisfactorily settling the questions at issue. Among the treaties with foreign nations now in force are extradition and reciprocal naturalization treaties recently concluded with the United States.—The crown lands (*miri*) include the larger portion of the soil. They are granted on lease, and forfeited if the cultivation is neglected for three years. The land appropriated to mosques and for other religious purposes, to schools, and to charitable institutions, consists of real estate originally granted by the crown (*vakuf el-zarai*), and of private legacies for the same purposes (*vakuf el-karamain*). The grants of land (*malikaneh*) originally made for military purposes and for the pilgrimages to Mecca are hereditary and free from tithes. The fourth and least considerable form of tenure is freehold property (*mulkh*), chiefly consisting of city estates and of land adjoining villages. Foreigners can now hold real estate in their own names, on the same terms as natives. The great Turkish landed proprietors are far more independent of the government than the landed aristocracy of Great Britain and continental Europe; the most ancient and powerful of them in Aidin, Brusa, and other parts of the empire, resemble feudal princes, but generally keep aloof from public affairs, and are distinguished for munificence and charity. Some of the Armenians also are vast landholders, and they as well as some of the Greek and other merchants have city and country palaces which vie in magnificence with those of the foreign ambassadors, of the great pashas, and of the imperial and Egyptian dynasties. The principal charter of civil rights, next to the *hatti-sherif* of 1839, was the *hatti-humayun* of 1856, which, as well as subsequent and quite recent pledges, promised great improvement and reforms, but have not produced permanent ameliorations, the orthodox Moslems being opposed to increased privileges for the Christians, while the latter insist upon much greater ones than the sultan is willing to concede.—The financial budget for the year 1875–'6, ending in March, estimates the revenue at $125,500,000, and the expenditures at $103,800,000. As usual, it is made to show a surplus, when in reality there is an immense deficit. The public debt of Turkey is divided into two classes, the foreign or hypothecated debts, contracted abroad and secured on special sources of revenue, and the internal debts, known under a variety of names, issued at Constantinople alone, and therefore dependent only on a compact between the Porte and its subjects, and secured on the general credit and resources of the empire. The nominal amount of the foreign debts had reached in January, 1874, the sum of $772,000,000, and the floating debt was estimated at $64,600,000. A new loan was issued in September, 1874, to consolidate the floating debt, which since January of that year had again largely increased. A financial report from Constantinople, dated May 10, 1875, estimated the entire Turkish debt at $969,600,000. On Oct. 8, 1875, the government declared its partial insolvency, and promised to pay half of the interest due on the foreign debt in cash, and the rest in new bonds to be issued to the extent of about $166,000,000. A reorganization of the army was begun in 1871, and is to be completed in 1878. According to the new regulations, the military forces (formerly divided into *nizam*, or active army, *idatyal*, first reserve, *redif*, second reserve, and *hiyade*, militia) are divided into the regular army, the reserve, and the sedentary army. In time of war the army is to contain 700,000 men, of whom 150,000 will belong to the regular army, 70,000 to the first reserve, and the remainder to the sedentary army. The annual contingent will be nearly 40,000 men. The imperial guard at Constantinople is the only thoroughly efficient military body in the empire. Non-Mussulmans are not liable to service in the army, but have to pay a military exemption tax, known as the *bedel*. Polish, Hungarian, French, English, German, and other foreigners are employed in the Turkish army and navy, some of them reaching high positions, such as the late Austrian Omer Pasha as commander in the former, and the English Hobart Pasha as admiral in the latter service. The navy consisted in 1874 of 20 iron-clad vessels and 99 transports, and was manned by 34,000 sailors and marines. The crews are raised in the same manner as the land forces.—The arrivals and departures in the Turkish ports in 1873 comprised 43,200 foreign vessels, tonnage 12,738,000, and 29,614 Ottoman vessels, tonnage 3,518,000, besides 178,143 small craft, mainly Turkish, engaged in the coasting trade, tonnage 1,903,000. The arrivals in 1874 at Constantinople, the chief port, comprised altogether 4,185 steamers (2,042 English) and 16,489 sailing ships (2,500 Greek and the rest chiefly Ottoman), with an aggregate tonnage of 4,606,200, or one fourth of the whole national trade. Much shipping business is carried on at Smyrna, Salonica, and Trebizond. Adrianople, Aleppo, Damascus, and Bagdad are the most prominent interior commercial centres of the empire. The imports consist chiefly of British and other manufactures and colonial goods, and the chief exports comprise grain, cotton, fruit, wine, tobacco, coffee, honey and wax, silk, emery, carpets, and madder. The average annual estimated value of imports into European Turkey in 1868–'70 was about $90,000,000, and of exports $50,000,000; there are no trustworthy later data, and none at all in regard to Asiatic Turkey. The exports to England in 1874 amounted to £6,000,000, and the imports from that country to £7,000,000; the exports to Russia, about 20,000,000 rubles, and the imports 6,000,000 rubles. The imports from the United States amounted, in the year ending June 30, 1874, to $2,559,551, and the exports to $786,877.—With the exception of a few great thoroughfares, there are no roads worthy of the name throughout the empire. The first railway dates from 1862. The principal railways (1876) are those from Constantinople to Adrianople, Varna to Rustchuk, Kustendji to Tchernavoda, Salonica to Mitrovitza, and Novi to Banialuka, in Europe, and from Smyrna to Ephesus, Aidin, and Alashehr, and Scutari to Ismid, in Asia Minor. According to a convention with Austria, Sept. 30, 1875, the Belovar-Sofia line was to be completed in 1876, and its extension to Nissa and connection with Belgrade in 1879. The aggregate length of railroads finished in European Turkey is nearly 1,000 m.; in Asiatic, not much more than 100 m. The Danube with its navigable tributaries forms the great channel of commerce for the northern portions of Turkey in Europe. The lines of telegraph have an aggregate length of 17,364 m., and the wires of 28,973 m. There were 400 telegraph offices. The communications with the interior were of the most inefficient description until March 1, 1876, when the entire postal service of the empire was for the first time undertaken by the government, which proposes to organize it after the best European models.—The Ottoman empire, including its dependencies, almost closely corresponds to the Byzantine empire in the times of its greatest extent. It arose when the latter had been stripped by Saracen and Seljuk conquest of all its possessions in Asia and Africa, excepting some territories in the north and west of Asia Minor. It derives its name from Othman or Osman, the successor to the power of the Seljuk sultans of Iconium or Roum, who conquered Nicæa in Bithynia (1299) and several neighboring districts. (See SELJUKS, OTHMAN, and TURKS.) The Ottoman power was increased by his son Orkhan's capture of Brusa, the Bithynian capital (1326), and by his invasion of Thrace. Othman's grandson Amurath I. took Adrianople in 1361, regularly organized the janizaries (see JANIZARIES), vanquished the princes of Bulgaria and Servia, and was killed at the moment of his signal victory over the Serbs at Kosovo in 1389. His son Bajazet I. invaded Wallachia and Hungary, besieged Constantinople for several years and then retreated, defeated Sigismund of Hungary at Nicopolis (1396), and overran the Morea; but having previously completed the conquest of Asia Minor, he was obliged to evacuate Greece and to protect the former region against the invasion of Tamerlane, by whom he was finally defeated and captured in 1402, a year before his death. His grandson Amurath II. (1421–'51), son of Mohammed I., conquered Thessalonica and Janina. He was defeated by Hunyady at Belgrade in 1439, and on subsequent occasions, but in 1444 achieved a great victory over Hunyady and King Ladislas of Poland and Hungary at Varna. He overwhelmed the Hungarians in a second battle at Kosovo, three years before his death. His son Mohammed II. (1451–'81) gave the final death blow to the Byzantine empire by his conquest of Constantinople, after a memorable siege of 53 days, May 29, 1453; and in 1454 he completed the conquest of Servia. At Belgrade he was repulsed by Hunyady (1456), but he subdued most of the Morea (1460), and soon afterward Trebizond, Wallachia, and almost all the islands of the archipelago. He was repeatedly defeated by Scanderbeg in Albania, and subjugated that country only after the latter's death (1467). Mohammed was the founder of the greatness of Turkey, and was surnamed the Conqueror. Remarkable among his successors was Selim I. (1512–'20), son of Bajazet II., who extended his dominion over Mesopotamia, Assyria, Syria, and Egypt, and established a regular Ottoman navy. His son Solyman II., the Magnificent, took Belgrade in 1521 and Rhodes in 1522, defeated the Hungarians at Mohács in 1526, captured Buda in 1529, and marched on Vienna, where he was repulsed with great loss, and again in 1532. Subsequently he conquered Armenia, Croatia, Yemen, Shirvan, and Georgia; but his naval forces, which had extended his sway over the Barbary coast, were defeated at Malta in 1565, and in 1566 he was repeatedly repulsed by Zrinyi at Sziget, and died a few days before the last and fatal assault on that Hungarian fortress. The reign of Solyman marks the zenith of the military power of Turkey, which began to decline after his death, his son Selim II. being the first of the sultans who did not command the troops, and who led the life of a voluptuary. After conquering Cyprus, he lost in 1571 the great naval battle of Lepanto. He was succeeded by a series of still more inefficient rulers, under whom the janizaries became omnipotent despite the decline of their military organization, and murders and conspiracies in the seraglio and revolts of pashas in remote provinces more and more frequent. The more important of these sultans were Amurath III. and IV., Mohammed IV. (who conquered Candia after a protracted struggle), and Mahmoud I., accounts of whose reigns are given under their own names. Frequent wars with Poland, Austria, Persia, Venice, and Russia were waged, but rarely with success. Montecuculi, Sobieski (who routed Mohammed IV.'s army before Vienna in 1683), Louis of Baden, and Prince Eugene destroyed the Turkish power on the Danube; and at the peace of Carlovitz in 1699 Mustapha II. surrendered nearly all his Hungarian possessions to Austria, Azov to Peter the Great of Russia, Podolia and Ukraine to Poland, and the Morea to Venice. During almost the whole of the 18th century Turkey was at war with Russia, and much of the time with Austria also. Though occasionally successful, as in the reconquest of the Morea under Ahmed III. (1715), this protracted warfare was disastrous to Turkey, and she lost the Crimea and all her possessions N. of the Black sea, and the exclusive navigation of that sea and the straits connected with it. In other quarters, too, losses were suffered. Selim III. (1789–1807) was an enlightened ruler, but could not avert continuous disasters. The peace concluded with Russia at Jassy in 1792 made the Dniester the frontier between the two empires. Several provincial governors aspired to independence, and the conquest of Egypt by Bonaparte led to a war with France, which ended in considerable concessions to that power; and wars with Russia and England and the revolt of the janizaries aggravated the critical condition of the country. Servia rose under the leadership of Czerny George (1805), and subsequently achieved its semi-independence under Milosh Obrenovitch. Selim was deposed in 1807, and Mustapha IV. was placed on the throne chiefly through the influence of the janizaries, but was displaced and put to death in 1808 by his brother Mahmoud II., who after a terrible struggle finally disbanded that body in 1826, massacring thousands of them. In the mean time he had also displayed great energy in Albania by crushing Ali Pasha of Janina (1822), but the Greek revolution proved fatal; and as Mahmoud disregarded the European remonstrances against the cruelties perpetrated in Greece by Ibrahim

Pasha and others, the Turco-Egyptian fleet was destroyed by the English, French, and Russian squadrons at Navarino, Oct. 20, 1827. Hostilities virtually ceased in 1829. Greece achieved her independence, and after a victory by the Russians under Diebitsch, who had crossed the Balkan, the treaty of Adrianople, Sept. 14, 1829, restored peace between Russia and Turkey. In 1832 began the contest of the Porte with Mehemet Ali, the viceroy of Egypt. The sultan was repeatedly defeated, and the struggle was not ended at the time of his death (1839), and only a year after the accession of his son Abdul-Medjid, through the intervention of England and her allies in behalf of the Porte, whose admission into the political system of European states was for the first time officially conceded by the treaties of July 15, 1840, and July 14, 1841. The integrity of Turkey became a cardinal principle of European diplomacy, and was strengthened by the coalition of England, France, and Sardinia with Turkey in the Crimean war (1853–'5), which resulted in the discomfiture of Russia, and the neutralization of the Black sea by the treaty of Paris (1856). A French army and an English fleet again interfered in 1860 to terminate the conflict between the Druses and Maronites, after fearful massacres of Christians at Damascus and in the Lebanon, and great loss of life on both sides. The reign of Abdul-Medjid was also troubled by conflicts with Montenegro, and a rising in Herzegovina. He died June 25, 1861, and was succeeded by his brother Abdul-Aziz. In December of the same year the Danubian principalities were permanently united under the name of Roumania, and in 1866 Charles I. of the house of Hohenzollern was elected hereditary prince. A Cretan insurrection broke out in the same year, and led to serious collisions with Greece, which were finally terminated by a conference of the great powers at Paris, Jan. 9, 1869. In the mean time Servia had taken advantage of these complications to obtain (1867) the independence of all her fortresses; while Egypt, after coöperating with Turkey in Crete, made extravagant pretensions which would have resulted in war but for the influence of foreign powers. The Franco-German war (1870–'71) impaired the prestige of the Porte's steadiest ally, and enabled Russia to recover her former vantage ground in the East by insisting upon a modification of the treaty of Paris of 1856 (November, 1870), and its provisions which had neutralized the Black sea ports and other articles restricting Russia were abrogated by a conference in London, January, 1871. The grand vizier Aali Pasha died in the same year, and Fuad Pasha having died two years before, Abdul-Aziz was deprived of his most influential advisers. After vain attempts to check the ambition of Egypt, the sultan finally granted (June, 1873) important privileges to the present khedive, Ismail Pasha, making him almost an absolute ruler. In July, 1875, the Turkish port of Zeilah, in the gulf of Aden, was added to Egypt, bringing the entire African coast of the Red sea under her domination. In November the khedive transferred all his shares in the Suez canal to England, without apparently asking the consent of the Porte or any other government. In the summer of 1875 an insurrection broke out in Herzegovina, and in October Turkey declared her partial insolvency. Other grave complications threatening a dismemberment of the empire, the six powers who had signed the treaty of Paris of 1856 proposed a scheme of reforms in February, 1876, which the sultan mainly accepted; but the insurgents refused to lay down their arms, and his situation became more and more critical, and was greatly aggravated by the opposition of the Turkish fanatics to Christian equal rights, and the massacre of the French and German consuls at Salonica in May. A conference at Berlin between Russia, Austria, and Germany contemplated more exacting terms for the protection of the Christians and restoration of tranquillity, but England took no part in it. The adversaries of Abdul-Aziz, prominent among whom were the *softas*, comprising about 20,000 students in Constantinople, who were alienated by his alleged subserviency to Russia, his refusal to restore his spoils (which were afterward confiscated), and his attempted change of the order of succession, brought about his deposition on May 30, and the accession of his nephew as Amurath V., who on June 4 announced his predecessor's alleged suicide. The new sultan is beset by formidable financial and other difficulties. Herzegovina is still in revolt (June, 1876); Servia, Montenegro, and Bosnia maintain a threatening attitude; and Bulgaria and other provinces are disaffected. But the European powers, and especially England in her antagonism to Russia, strive to prevent the dismemberment of Turkey, although the general confidence in the stability of Ottoman domination over Christian communities has never since the conquest of Constantinople been so low as now.—See *Geschichte des osmanischen Reichs*, by Hammer-Purgstall (10 vols., Pesth, 1827–'34); "History of the Ottoman Empire," by E. Upham (2 vols., Edinburgh, 1829); *Geschichte des osmanischen Reichs in Europa*, by Zinkeisen (7 vols., Gotha, 1840–'63); *L'Asie Mineure*, by P. Tchihatcheff (8 vols., Paris, 1853–'69); "The Turkish Empire," by E. Joy Morris (Philadelphia, 1854); *Histoire de la Turquie*, by Lamartine (6 vols., Paris, 1854); "History of the Ottoman Turks," by E. S. Creasy (2 vols., London, 1854); *Geschichte der Türkei neuester Zeit*, by Rosen, (2 vols., Leipsic, 1866–'7); *Études historiques sur les populations chrétiennes de la Turquie d'Europe*, by Ubicini (Paris, 1867); "Modern Turkey," by J. Lewis Farley (London, 1872); and *Der Islam im neunzehnten Jahrhundert*, by Vámbéry (Leipsic, 1875).

TURKEY BUZZARD, the popular name of one of the common American vultures, *cathartes* (*rhinogryphus*) *aura* (Illig.). It is about 2½ ft. long and 6 ft. in extent of wings; the bill is long and comparatively slender, with an arched, strong tip; a large soft cere, two thirds the length of the bill, in which the pervious nostrils are placed; wings long and pointed, the third and fourth quills nearly equal and longest; tail moderate and nearly even; tarsi short, plumed below the knee, and with small scales; toes weak, united by a small membrane, hind one short and weak, and claws strong; head and neck naked, no fleshy crest, and the plumage black. All the vultures which have the nostrils horizontal and perforate, with a basal web between the middle and inner toes, belong to the new world. The color is brownish black, with a purplish lustre, darkest on the back and upper part of tail, and some pale edgings; bill yellowish; head and neck bright red, with a few scattered hair-like feathers and wrinkled skin; plumage commencing on the neck with a circular ruff of prominent feathers. It is found all over North America, except the arctic regions, going on the Pacific coast as far N. as the British possessions, but on the Atlantic rarely seen N. of New Jersey; but it is most abundant in the southern states, migrating thither from the colder parts. It is essentially a carrion eater, though it will devour any kind of fresh meat, and even small living mammals, birds, and reptiles; it has been known to attack and kill weak and sickly animals in the fields. It associates in flocks of 25 to 30, even when not feeding, becoming very familiar in the southern cities, where it devours any carrion or animal filth left in the streets. It finds out its prey at a great distance, and sails for miles without apparent effort, with the tips of the wings bent upward by the weight of the body; it is often seen in company with the black vulture, hawks, kites, and crows; it is also a good walker. Its average weight is 6½ lbs., which is somewhat less than that of the black vulture. It is fond of particular roosting places, generally high and dead cypresses in deep swamps; it is very sensitive to cold, and liable to disease about the eyes and legs in the shape of warts and excrescences; when alarmed or provoked it utters a loud hissing noise. In the southern states the breeding season begins early in February, the nest being usually placed in the hollow of a dead tree, or, it is said, even on the ground, and containing two eggs, 2¾ by 2 in., light cream-colored, with black and brown marks; both sexes incubate, each feeding the other and the young with the disgorged contents of the stomach; incubation lasts 32 days; only one brood is raised yearly.

Turkey Buzzard (Cathartes aura).

TURKISH LANGUAGE AND LITERATURE. The languages spoken by the different tribes of Turkish or Tartar origin form a principal division of the great Uralo-Altaic or Turanian family, of which the chief common characteristics have been pointed out under Turanian Race and Languages. They constitute together a well marked group of nearly related idioms; even the Yakut—the one which differs most from the rest, and is supposed to have severed itself from the main stem before the division of the latter into its other branches—is so distinctly a Turkish language that its relationship is apparent upon the most superficial examination; and it has been asserted, though with questionable accuracy, that a Yakut from the Lena could make himself passably understood at Constantinople. The Tartar dialects are for the most part known only by scanty vocabularies and the descriptions of travellers; a few have been treated grammatically; three or four, as the Uigur, the Jagatai or oriental Turkish, and the Osmanli, have received literary culture, and are to be studied in written monuments. Of these last, the dialect of the tribe which has been for 500 years dominant in European and Asiatic Turkey, or the Osmanli Turkish, as it is distinctively called, is of by far the greatest importance, and to it we shall chiefly direct our attention. Its peculiarities are such as naturally result from its position and its culture under the powerful influence of Arabic and Persian; every part of its vocabulary, and even some departments of its grammar, are filled with Arabic and Persian elements; so that it presents the remarkable and unique spectacle of a dialect made up of materials derived from the three grand and totally disconnected families of language, the Turanian, Semitic, and Aryan or Indo-European, to the detriment, of course, of its native character, by the corruption of its forms and the artificiality of its style. This is true especially of the language taught in the grammars and written in the literature; the vernacular idiom of the people is a much purer Turkish. The Osmanli is usually written with the Arabic alphabet, which is exceedingly ill suited to it, as to the Persian, since it marks the vowels very imperfectly, and in its distinction of consonantal sounds is in part defective and in part redundant; to construct the spoken alphabet and phonetic form of the language from the published grammars is well nigh impossible. It is also sometimes written with the Armenian alphabet, which represents it much more faithfully. It has nine vowels: four hard, *a*, *o*, *u*, and a peculiar guttural *i;* and five soft, *ä* (*a* flat), *e*, *i*, *ö* (French *eu*), and *ü* (French *u*). In the same word, as a general rule, only vowels of one or of the other of these classes are allowed to succeed one another; the dominant syllable, which is usually the final one of the root or theme, assimilating to its own character all that follow it. The consonants are *y*, *r*, *l ; ng*, *n*, *m ; s*, *z*, *sh*, *zh ; kh*, *gh*, *f*, *v ; k*, *g*, *t*, *d*, *p*, *b ; h ;* and the compounds *tch*, *j*. The language has no proper articles, although its numeral "one" and its demonstrative are sometimes used nearly as articles. The adjective is uninflected. The nouns have no distinction of gender; their plural is formed by the addition of *lar* or *ler*. There is no nominative case ending; the unchanged theme is employed as subject, in address (vocative), and also as indefinite object of a verb. Of cases, formed by inseparable affixed particles, which may properly be regarded as terminations of declension, there are an accusative, in *i ;* a genitive, in *ung ;* a dative, in *e ;* an ablative, in *den ;* an instrumental, in *le ;* and a locative, in *de*. These affixes are, saving certain slight euphonic changes, invariable; they are appended to the simple theme in the singular, and to the plural sign *ler* in the plural. The numerals are: 1, *bir ;* 2, *iki ;* 3, *ütch ;* 4, *dort ;* 5, *besh ;* 6, *elti ;* 7, *yedi ;* 8, *sekiz ;* 9, *dokuz ;* 10, *on ;* 11, *on bir*, &c.; 20, *yeyirmi ;* 30, *otuz ;* 40, *kirk ;* 50, *elli ;* 60, *eltmish ;* 70, *yetmish ;* 80, *seksen ;* 90, *doksan ;* 100, *yoz ;* 1000, *bing*. To form the ordinals, *inji* is added. The personal pronouns, which alone offer some anomalies of declension, are: I, *ben ;* we, *biz ;* thou, *sen ;* ye, *siz*. In the third person we have rather a demonstrative than a personal pronoun: that one, *ol ;* those, *anlar*. Possessive pronominal suffixes are: *m*, my; *miz*, our; *n*, thy; *niz*, your; *i* or *si*, his, hers, its; *lari* or *leri*, their. These are appended directly to the nominal theme, singular or plural, and the affixes of case follow them, as *baba-lar-um-dan*, from my fathers. There is no relative pronoun, except the Persian *ki*. The verbal roots are not always reducible to a monosyllabic form. From each root are formed a number of themes of derivative conjugation, by adding conjugational affixes; these are: for the passive, *il ;* for the reflexive, *in ;* for the reciprocal, *ish ;* for the causal, *der ;* and for the negative *me ;* which last, by prefixing *e*, becomes a sign of impossibility. Any or all of these affixes may be combined at once with a verbal root, so far as the idea admits of their combined modification; so that in theory we may have as many as 36 themes from one root, each conjugated throughout in the same manner as the simple root: *e. g.*, from *sev-mek*, to love (*mek* is infinitive affix), come *sev-il-me-mek*, not to be loved; *sev-der-il-mek*, to be made to love; *sev-ish-il-eme-mek*, not to be able to be loved by one another, &c. The root of the verb, without affix, is the second person singular imperative: *e. g.*, *sev*, love! The tenses and moods are of two kinds, simple and periphrastic. The former are formed either by appending a predicative pronominal suffix to a participle (except in the third person, which is left without suffix), or by adding a possessive suffix to a noun of action; thus, from *dogmak*, to strike: pres. part. *dogur*, striking; pres. *dogur-um*, striking-I, *i. e.*, I am striking, I strike; pret. *dogd-um*, striking-mine, *i. e.*, I have struck. The periphrastic tenses are formed by combining a participle or noun of action with an auxiliary verb; as *dogmish idum*, having struck was I, *i. e.*, I had struck. By these means, a great variety of more or less genuine verbal forms is produced, in the admission and classification of which, however, grammarians greatly differ; and the verbal paradigm is a very rich one as regards the number and nicety of its distinctions. What are prepositions in other languages are in Turkish postpositive affixes; but many proper prepositions are borrowed by it from the Arabic and Persian, and are placed and construed according to the usage of those languages. It is almost entirely destitute of any conjunctions except those of Arabic and Persian origin, some of which—as those for and, but, or, if, as, that—are in frequent and familiar use, although more in the formal and written style than in the conversational. The place of conjunctions is supplied by gerundives and possessive forms, through means of which the different members of a compound sentence are twined into one, with the principal verb always at the end. This position of the verb, together with the operation of the rule that the determining word must precede the determined, gives the Turkish construction an inverted form which often seems very strange.—LITERATURE. The earliest literature produced by any of the divisions of the Turkish race is that of the Uigurs, a remote eastern branch of the family, who originally occupied the country south of Lake Baikal, but later established themselves about the Tangnu Tagh, and played a conspicuous part in the contests and migrations of central Asia during several centuries, until their nationality was swallowed up in the Mongol empire, about A. D. 1200. Something of culture and Christianity was communicated to them from Syria, doubtless by Nestorian missionaries; and their scanty alphabet, of 14 characters, formed from the Syriac, became later the parent of the Mongol and Mantchoo alphabets. Most of the Uigur literature is lost, and of what remains only a few relics have found their way to Europe; little is known of it in detail, although it has been made to yield some information respecting the history of the people. They are said by the Chinese to have received and translated the Chinese classics and histories, and they are known also to have adopted to some extent the Buddhist doctrines and literature. The second era of Turkish culture dates from the conquest by Turkish tribes of the countries of Mohammedan Asia, beginning with the latter half of the 10th century. Overrunning first the N. E. provinces of Iran, and finding there the new Persian literature beginning its career, their wild chiefs became its admirers, patrons, and imitators, and the Turkish mind and language received that strong Persian impress which they have ever since borne. The eastern Turkish literature, or that produced beyond the Caspian, is usually called the Jagataian, from the name given to the country E. of the Oxus in the partition of the Mongol empire. It is much less abundant, and also much less known, than the literature of the western branch. Its most flourishing period was from the time of Tamerlane (1400) to that of Baber (died 1530). Its most admired author is Mir Ali Shir, the vizier of Sultan Hussein, and a munificent patron of Persian authors, particularly of the poet Jami; his most interesting work, perhaps, is his collection of biographies of earlier Jagataian poets, with specimens of their productions. The memoirs of his own life and times by Sultan Baber, the conqueror of Hindostan and founder of the Mongol dynasty, cover a period of nearly 40 years, and are written with entire simplicity and naturalness. The astronomical works prepared at Samarcand, under the patronage and direction of Ulugh Beg (died 1449), grandson of Tamerlane, deserve honorable notice.—The literature of the western or Osmanli Turks, to which alone we usually apply the name of Turkish literature, is exceedingly rich, but it is upon the whole of inferior interest, because it contains so little that is original and distinctively national in style and spirit. It is mainly an imitation, more or less successful, of Persian models, but in part also of Arabic. As the language of the Osmanlis is full of Persian words, compounds, phrases, and even forms of construction, so is their history, their philosophy, their poetry, a reworking of Persian material, an echo of Persian taste. The history of the Osmanli literature begins with that of Osmanli nationality; even before the power of the dynasty was established by the capture of Constantinople, works had been produced which the nation has never let perish, and has hardly excelled; prominent among the great names of this era are those of Sheikhi, the romantic poet, and also the ablest physician of his time, of Solyman Tchelebi, and of Nesimi the free-thinker. But the most flourishing period in the whole history of the literature was the 16th century, chiefly during the reigns of Solyman the Magnificent and his son Selim II. Meshihi, renowned as an elegiast, and Kemal Pasha Zadeh, a man of universal learning and an admired author in many different departments, especially in history and in Moslem jurisprudence, wrote early in the century. Both these branches are of great importance and prominence in the Turkish literature. The latter, of inferior interest to us, but of the highest consequence to the Turks themselves, in its double aspect, religious and legal, and indispensable to those who would fully understand the internal life of the nation, is illustrated by an unbroken series of great writers. In history, besides general and independent authors, such as Mohammed Effendi, Betchevi, and Hadji Khalfa, the line of official historiographers and annalists of the realm, commencing with Saad ed-Din, deserve especial notice. Among his successors were Naima, Reshid, Izzi, and Vasif. Notwithstanding the turgid and affected style of the official historians, they are most valuable authorities for the history of the Ottoman empire, in its internal and its external relations. Saad ed-Din wrote under Solyman, and has been excelled by none who came after him in dignity and philosophic spirit; he brought the story of the rise and growth of the Turkish power down to 1526. Of the same period is Lami'i, one of the most highly esteemed of Turkish authors, and in some departments quite unsurpassed; his works are both in prose and verse, and include many translations from the Persian. Fasli, distinguished by depth of thought and tenderness of sentiment, lived till 1563. But the chief ornament of the century is Baki, the acknowledged prince of Turkish lyric poets, and ranked by the orientals with the Persian Hafiz and the Arab Motanebbi in the trio of unrivalled masters of song. He died at a great age in 1600. A new period of literary activity and excellence, although decidedly inferior to that already referred to, followed in the 17th century, under the patronage of the great vizier Köprili, in the reign of Mohammed IV. Most worthy of note here are Nebi, the most admired poet of the century, Nefi, the first of Turkish satirists, Naima the historian, and Hadji Khalfa, the historian, geographer, biographer, and encyclopædist, a man of immense learning and industry, whose history of Arabic, Persian, and Turkish literature, in Arabic, is a chief authority upon its subject, for both the East and the West. In the 18th century, the distinguished vizier Raghib Pasha is eminent both as an author and as a patron of learning; but among the innumerable writers, in every department, of the last century or two, there are few who deserve to be particularly noticed; we may mention merely Said Rufet Effendi, Aini Effendi, and Pertev Effendi as the most esteemed poets. The Turks have done little for the grammatical and lexicographical illustration of their own language, but a great deal for that of the Arabic and Persian. The press was introduced into Constantinople early in the 18th century, by Ibrahim Effendi, and, both there and elsewhere, has been actively engaged in publishing the most important works in Arabic, Persian, and Turkish, especially the last (including the series of official histories), together with hosts of less valuable or altogether insignificant productions. Many translations have been made by the Turks of European as well as oriental works. Among original works are a history of the Turkish sultans by Hajruhah Effendi (1854 *et seq.*), the biographical works of Resnü Ahmed Effendi and Faik (1853), the works of travel by Mehemed Khurshid Effendi (1861), and Prince Subti's numismatical writings (1862). Several societies have been established in Constantinople for the promotion of various branches of scientific research, and besides the regular journals of these, several literary and scientific magazines of some merit are now published. The most accessible and useful grammars are those of Davids (London, 1832) and Redhouse (in French, Paris, 1846). Kazem-Beg's grammar (in Russian; German by Zenker, Leipsic, 1848) includes also the other dialects, and is valuable for the comparative study of the language. Böhtlingk's Yakut grammar (in German, St. Petersburg, 1851) is also important in this bearing. Of chrestomathies, we have one by Dieterici (in French, Berlin, 1854), and Barker's reading book, grammar, and vocabulary (London, 1854). The best dictionaries are those of Kieffer and Bianchi (2d ed., Paris, 1843–'6, Turkish-French), and Redhouse (London, 1856–'7). A new and more complete one, by Zenker, explained in French and German, and embracing the Turkish, Arabic, and Persian languages, is now (1876) nearly completed.

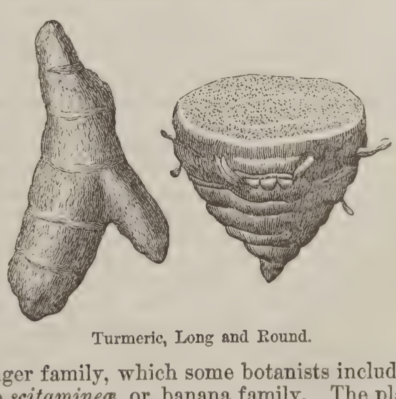
TURKISTAN, a region of central Asia, extending from the Caspian sea eastward half way across the desert of Gobi, mainly between the 36th and 46th parallels of N. latitude, bounded N. by the Russian dominions, and S. by Persia, Afghanistan, India, and Thibet. Its name is due to the fact that it is considered the earliest known abode of the Turks or Turkomans, and thus as a seat of the Tartar race it has also long been called Tartary. The region is separated into the two great natural divisions of East and West Turkistan by the junction of the Thian-shan mountains with the Hindoo Koosh in the lofty table land of Pamir, which is a ridged plateau, rising W. of Kashgar to an average altitude of 15,000 ft. above the sea. According to Humboldt, the two great ranges are united by a transverse chain, called the Belur or Bolor Tagh (Cloud mountains), bordering Pamir on the east, the separate existence of which, however, is rendered doubtful by recent explorations, although commonly assumed on maps of Asia.—West Turkistan, formerly known as Independent Tartary, comprises the khanates of Khiva and Bokhara, the former khanate of Khokan, annexed by Russia in March, 1876, the territories previously annexed by Russia from the three khanates, and in the south Wakhan, Badakhshan, Koondooz (including Khooloom), and Balkh, lately incorporated into Afghanistan. East Turkistan, also called Chinese Tartary, is the extensive region E. of the table land, in which Kashgar is now the paramount state.—The hydrographic systems of Turkistan originate in the lofty, lake-studded region of culmination which we have mentioned. On the southern edge of the Pamir steppe, in the Sir-i-kol (Lake Sir), according to the latest authorities 13,900 ft. above the ocean, rises the Oxus or Amoo Darya, flowing westward down the steep slope of the plateau through Bokhara and along the border of Khiva into the sea of Aral. The Sir Darya or Jaxartes, which under the name of the Naryn has its source in the Thian-shan range 300 m. N., and also empties into the Aral sea, waters Khokan and the N. part of Russian Turkistan. Between these two great rivers, and enclosed by parallel ranges stretching westward from the central table land, runs the smaller Zerafshan, in whose fertile valleys are the cities of Bokhara and Samarcand. Though naturally an affluent of the Oxus, its waters are exhausted for irrigation. Down the eastern and more gradual slope of Pamir into Chinese Tartary flow numerous streams, of which the most important are the Yarkand and Kashgar rivers, which are believed to coalesce with others to form the eastward-flowing Tarim, emptying into Lob-nor, the great lake or swampy expanse of the Gobi desert.—Of West Turkistan, Khiva, Bokhara, Khokan, Badakhshan, and Balkh have been described under their own titles. The territory is naturally divisible into three physical regions. The first comprises the more elevated mountainous districts among the outlying spurs of the Pamir steppe, which afford rich summer pasturage for the flocks of the hardy inhabitants. Thence flow innumerable torrents to the Oxus, the Sir Darya, and their tributaries, and enrich the alluvial soil of their upper valleys and plains, constituting the second distinctive region, which is populous, fertile, and well cultivated. Here are found the principal cities. Still further westward toward the sea of Aral, the area of cultivation ceases, and the rivers flow through the third region, comprising vast tracts of arid saline deserts, only relieved at the delta of the Oxus by the facilities there for irrigation. Almost the entire country stretching from the shores of the Caspian eastward to the valley of the Oxus, and from lat. 45° southward to the frontiers of Persia and Afghanistan, is occupied by the Turkoman steppes, including the Ust-Urt plateau between the Caspian and the sea of Aral, of which the Tchink mountains constitute the S. declivity, and the Khiva or Kara-Kum desert, S. of Khiva. Many parts of these sandy and trackless wastes are below the level of the sea. The ancient bed of the Oxus leading to the Caspian traverses the country, whose chief rivers now are the Murghab from Afghanistan, which loses itself in the sands N. of the town of Merv, and the Attrek, on the southern border. The wells of the desert yield only brackish or bitter water. Almost all is confined to their vicinity or that of the streams. The climate is always dry, exceedingly hot in summer, and very cold in winter, which however is short. Salt and sulphur are obtained on the steppes. The animals of the desert comprise gazelles, horses, asses, pigs, foxes, and hares.—Although preserving a nominal independence, Khiva and Bokhara are practically subject to Russia. The portions annexed by the Russians previous to the annexation of Khokan in 1876 have been united with a part of the Siberian province of Semipolatinsk to form the government general of Turkistan; area in 1875, about 400,000 sq. m.; pop. about 2,000,000. It comprises all that part of the country which is N. of the khanates and the Thian-shan range, from Kulja inclusive on the east (see KULJA) to the sea of Aral on the west, with the lower course of the Oxus for the S. W. frontier. But Kulja is usually regarded by geographers as belonging not to Turkistan, but to Dzungaria or Sungaria, a country inhabited by Kirghiz, Olots, the once powerful tribe of the Dzungarians, and others, the Chinese portion of which lies between the Thian-shan mountains, the Altai, and Mongolia. The western part of Russian Turkistan is overspread with steppes. The desert of Kizil Kum (red sand) occupies the region between the Oxus and the river which gives the province its name. The eastern part of the government general is mountainous. It is drained by the river Ili, flowing into the great Balkash lake, and the Tchu river, flowing N. W. from the vicinity of the more southerly lake Issik-kul. Lake Balkash is 780 ft. above the sea level, and has an area of 400 sq. m., while Issik-kul covers about 335 sq. m. of surface at an altitude of 4,540 ft. The most populous parts of Russian Turkistan (exclusive of Khokan) are in the vicinity of the principal towns, Tashkend, Samarcand, and Khojend. The plains are permanently habitable and capable of cultivation only in the neighborhood of the watercourses. The mineral wealth of Russian Turkistan, especially in gold and coal, is supposed to be large, but remains undeveloped. The government is divided into nine administrative districts, besides Khokan. The governor general, who is also the military commander-in-chief, has his headquarters at Tashkend.—The fundamental classification of the inhabitants of West Turkistan, according to Mr. R. B. Shaw, is into Turks or Tartars and Tajiks or Aryans. A cross classification is into the Kirghiz or nomads and the Sarts or settled population. In the towns of West Turkistan the Tajik element predominates in numbers, except in Khokan. In this race the features are handsome, the complexion fair, the face usually bearded, and there is a general resemblance to the Aryans of northern India. The language of the Tajiks is a variety of Persian. In the khanates the Uzbecks are the ruling class, whose nomadic kinsmen are the hordes of Kirghiz in the north and east, and the Turkomans of Khiva and the adjacent steppes. The Kirghiz are described as stunted in appearance, with prominent cheek bones, flattened noses, and scarcely any beard. The Uzbecks of the towns are handsomer, with some resemblance to the Tajiks in many cases. The Turkoman is generally above middle stature, powerfully developed, with a white skin, round head, small nose and chin, and scanty whiskers. A careful estimate of all the tribes indicates that their number is about 8,000,000 persons. They are fierce, haughty, and given to deeds of rapine and plunder, irascible and violent, but usually truthful and hospitable. All the tribes mentioned are Sunni Mohammedans.—The commerce of the country is considerable, and is conducted entirely by means of caravans. Native productions form but a small part of this commerce; but the towns are convenient places of exchange for the products of Russia, Persia, Afghanistan, India, and the Chinese empire. The manufactures consist chiefly of some silk and cotton stuffs, sabres, knives, and other weapons. The exports are cotton, mostly from China, wool from Thibet, fruits, hides, sheepskins, and silk. The imports are muslins, brocades, sugar, shawls, and white cloths from India; European manufactured goods from Russia; porcelain, musk, tea, rhubarb, and cotton from China; and wool from Thibet.—East Turkistan is bounded N. by the Thian-shan range, E. by the desert of Gobi, S. by Cashmere and Thibet, and W. by the Pamir plateau. Its area is estimated at about 500,000 sq. m., and its population at from 600,000 to 1,000,000. The country has long been denominated Alti-shahar or Alti-tchakan (the six cities), from the towns of Kashgar, Yarkand, Khoten, Yang-shahr, Ush-Turfan, and Aksu, which constitute its principal centres of population and trade. It is now divided into seven provincial governments under the ruler of Kashgar. The portion bordering Pamir is extremely mountainous, as are also the northern and southern frontiers; but the interior is an extensive plain with a general elevation of from 3,000 to 5,000 ft., described by Shaw as resembling an immense bay with its convex side toward the mountains and its concave side toward the desert. The chief rivers are affluents of the Tarim, the course of which extends about 500 m. from the 81st meridian eastward into the desert; among them are the Khoten from the south, the Yarkand from the southwest, and the Kashgar from the west, all named from the largest cities on their banks. The climate is extremely dry, and the land is therefore a desert except where there is natural or artificial irrigation. The temperature in the west ranges from 26° below zero in winter to 150° above in summer, but in the east and south is more equable. Along the streams are fertile belts of productive soil, where the vegetation is most abundant, and under the intense heats of summer many of the semi-tropical fruits and vegetables ripen. The field crops are cotton, rice, wheat, hemp, flax, barley, and maize, while the gardens produce tobacco and melons, and the orchards of the more favored districts yield an abundance of apples, pears, peaches, apricots, and other fruits. The herds of cattle are very large, and afford the principal article of export. The wild animals are generally the same as those of West Turkistan, with the addition of the tiger, the panther, and a peculiar species of stag found in the Lob-nor region of forest, jungle, and reed growth. The minerals are gold, found in the mountain streams and in the Thian-shan mountains, silver, iron, copper, nitre, sal ammoniac, sulphur, asbestus, agate, and the precious jasper, which was formerly a monopoly of the Chinese empire. The inhabitants are not so distinctly classified as the tribes of West Turkistan, all of which, however, are represented in those parts of the country to which modern exploration extends. The Turanian element is most prominent, although Shaw regards the Yarkandees as Tartarized Aryans. The inhabitants of the Lob region are a wild race of huntsmen, concerning whom little is known. The ruling class consists mainly of Uzbecks and Kiptchaks. Sunni Mohammedanism is the prevailing religion. The villages are made up of aggregated enclosures, each wall surrounding a house and a garden or fields.—The western part of Turkistan was known as Turania to the ancient writers on Persia. It was the theatre of repeated terrible conflicts between the Iranian or Persian and the Turanian races, in the early ages of Persian history, and the Persian hero Jemshid figures as largely in some of these as Achilles in those of the early Greeks. The Iranians finally remained masters of the southern part of the country, and at the beginning of the historic period it was comprised in the Persian satrapies of Bactria and Sogdiana, which were afterward conquered successively by Alexander the Great, the Parthians, the later Persians, the Arabs, and the Tartars or Mongols of Genghis Khan and Tamerlane, under whom the Tartar elements almost entirely replaced the Indo-European. The Mongols ruled over the southern portion till about the beginning of the 16th century, when their sultan Baber, the future founder of the Mogul empire in Hindostan, was driven out by the Turkish tribe of the Uzbecks. The Uzbecks established a powerful monarchy, which continued about 160 years, and then separated into numerous independent khanates, of which Bokhara, Khiva, and the late khanate of Khokan are the modern representatives. For the history of the advance and establishment of the Russian power in this region, see Bokhara, Khiva, and Russia. The Russian province of Turkistan, already described, was established in 1865, and the influence of Russia is paramount throughout all this part of Asia. The various forts and towns are garrisoned by a military force, numbering in 1874 about 30,000 enlisted men. In East Turkistan the chief state is now Kashgar, and the history of the country is given under that title.—See Vámbéry's "Travels in Central Asia" (London, 1865), "Sketches from Central Asia" (1867), and "Bokhara, its History and Conquest" (1873); *Die Russen in Centralasien*, by Friedrich von Hellwald (1874); "Khiva and Turkestan," translated from the Russian by Capt. H. Spalding (1874); "England and Russia in the East," by Sir Henry Rawlinson (1875); and, as to East Turkistan, Robert Shaw's "High Tartary, Yarkand, and Kashgar" (1871), and "Kashmir and Kashghar," by Dr. H. W. Bellew, C. S. I. (1875), being a narrative of Sir Douglas Forsyth's embassy from India to Kashgar in 1873–'4.

TURKOMANS. See Turkistan, and Turks.

TURKS, one of the most important branches of the Turanian family. (See Turanian Race and Languages, and Turkish Language and Literature.) In former ethnological classifications they were sometimes set down as a Caucasian race, and in physical characteristics some of their tribes are nearly or quite Caucasian; but more recent science shows that they have no connection with the Aryan or Indo-European family. They made their first appearance in northern and central Asia among the Hunnic and Tartaric hordes who for several centuries before and after our era were the terror of the Chinese. (See China, vol. iv., p. 459, Huns, and Tartars.) Turk is used in central Asia as synonymous with Tartar, or to designate the Mongolians generally. Before the commencement of the Christian era a tribe of Turks had wandered westward as far as the Don; they are mentioned by Pliny under the name of Turcæ, and by Pomponius Mela under that of Iurcæ; while other tribes had not long after penetrated into the mountainous regions of Asia Minor. In the 4th and 5th centuries of the Christian era a portion of the Turks who had remained in N. W. China conquered two provinces of that country, which they organized as independent kingdoms, to which the Chinese give the names of Chao and Northern Liang; but the greater part of those who were driven out in the 3d century rallied around Lake Balkash, and after the 5th century made no further separate appearance in history. In the early part of the 6th century a new Turkish empire, apparently having its nucleus in what is now East Turkistan, threatened the peace of Asia. These Turks renewed their conflicts with China at the east, and with Persia at the southwest, and in 569 formed an alliance with Justin II., then emperor of Constantinople, for the overthrow of the Sassanides. But this Turkish empire (which the Chinese called Tu-kiu), like all the attempts of the Turks at imperial domination, was an agglomeration of dissimilar peoples in one huge nation, with no common bond of union or citizenship, and its very vastness contributed to its weakness. In 744 the empire was overthrown by the attacks of the Hoei-he or Hoei-hu, as the Chinese named them (the Uigurs of western writers), another Turkish tribe who had previously been subjects of the Tu-kiu empire. There were at this time, and had been for some centuries, eight distinct Turkish tribes or nations in central Asia. The Uigurs never attained to the vast power of their predecessors, but they were the first of the Turkish tribes to adopt a written language. At first they were Buddhists; but about the 4th century they became very generally disciples of Zoroaster, and in the 9th or 10th century embraced Islamism. In the west their empire was overthrown in 848 by the Kirghiz Tartars; but they maintained an independent kingdom in the valleys of the Thian-shan range till about A. D. 1000, when the increasing power of the Khitans in China compelled their emigration westward. The invasion of Genghis Khan overthrew the last remains of the Turkish empire in central Asia; but the prominent officers of that conqueror and his successors were taken from this very tribe of Uigurs on account of their superior intelligence. But meanwhile the Turks had been acquiring new territories in the west. In the 6th and 7th centuries they were already in possession of an extensive region in what is now Asiatic Turkey, and were pressing forward toward S. E. Europe. In the 9th and 10th centuries the Tulunides and Ikshides, who founded short-lived dynasties in Egypt before the Fatimites, were Turks. In the 9th century a Turkish dynasty, the Taherides, ruled in Khorasan; and their successors, the Ghuznevides and the Ghorides, extended their sway from Persia to India between the 10th and 12th centuries. But a more famous Turkish dynasty than either of these was that of the Seljuks, whose dominion extended in the latter part of the 11th century from the frontiers of China to the vicinity of Constantinople. (See SELJUKS.) Like its predecessors, this vast empire crumbled to pieces from its want of homogeneity, and the Seljukian sultans submitted to be tributaries of the Mongol emperors. About the beginning of the 14th century the Ottoman empire was founded by Othman, a Turkish chief, and in the succeeding centuries spread over a vast territory in Asia and Europe. (See TURKEY.) The Turkish tribes which had submitted to the Mongol invasion in the 13th century, and still remained in the region of the Thian-shan mountains, the Aral, and the Caspian, sent out colonies N. of the Caspian into that portion of southern Russia lying on the borders of the Black sea, where, under the name of Tartars, several tribes of them still occupy extensive territories. While acknowledging the Russian sway, they are still zealous Mohammedans. The Mongol invaders of Turkistan, instead of impressing their own habits and language upon the Turks of that country, gradually became identified with the people they had conquered; and eventually, the Turkish element again predominating, in the age following the death of Tamerlane they had invaded and subdued Armenia and the countries bordering on the Tigris and Euphrates. From this region they were expelled in the 16th century by the Sufis. In the same century the Uzbecks, a Turkish tribe, primarily inhabiting the southern provinces of Chinese Turkistan below the Thian-shan mountains, and said to be descendants of the Uigurs and the Naimans, made their way westward, and overran not only East Turkistan but the countries adjacent as far as the Euphrates, and were, after maintaining their power for more than a century, reduced to subjection by still another Turkish tribe, the Turkomans. The Turkomans and Uzbecks are now, in the ancient seat of the Turks, the principal remaining tribes of that powerful race. The Calmucks between the lower Volga and Don, the Bashkirs between the Volga and Irtish, and the Yakuts on the banks of the Lena, are also Turkish tribes. The Yakuts are the only Turkish race professing Shamanism.

TURK'S ISLANDS, or **Turques,** a group of islets in the S. E. extremity of the Bahama archipelago, about 90 m. N. of Hayti; pop. about 2,500. The population fluctuates greatly at different times, as many people annually come from the Bermudas to work at salt raking, returning when the season is over. The islands are completely barren, and all kinds of supplies are imported. Grand Key or Turk's is the principal island. Since Jan. 1, 1874, the group with the Caicos group has been under the legislative control of Jamaica. The ports of entry are Grand Turk, Salt Cay, East Harbor, and West Caicos. The chief export is salt. For the year ending Sept. 30, 1874, the entries were 5 steamers of 3,555 tons, and 344 sailing vessels of 47,879 tons; total value of imports, $100,622; of exports, $115,682.

TURMERIC, a name of unknown origin, given to the rootstocks of several species of *curcuma* (Pers. *kurkum*, the name also for saffron, and applied to this because of its similarly yellow color), especially to *C. longa*, plants of the ginger family, which some botanists include in the *scitamineæ* or banana family. The plants are indigenous to southern Asia, and are culti-



Turmeric, Long and Round.

vated in various eastern countries. They have perennial, palmately divided, tuber-like rootstocks, and annual stems; the large lanceolate leaves are radical, and from among them rises a short stem, bearing a thick spike, from between the bracteal scales of which the flowers appear in succession, much as in the related ginger and arrowroot, figured under their titles. In commerce the rhizomes are called roots, and are distinguished as long and round, though both are produced by the same plant, and are also known by the names of the localities of export, each of which has its long and round kinds. Long turmeric is about the size of the little finger, 2 or 3 in. long, curved, and tuberculated from a tendency to branch; the round is more usually oval, an inch thick and 2 in. long; both kinds are marked by transverse scars or wrinkles, are yellowish externally, and internally orange-yellow or reddish brown; they have an odor like that of ginger, but peculiar, and a warm aromatic taste, and when chewed tinge the saliva yellow; they form an orange-yellow powder, the condition in which they are generally kept in the shops. The drug contains about one per cent. of an essential oil, and a peculiar coloring matter, curcumine, which is crystallizable, almost insoluble in water, but very soluble in alcohol and ether. Turmeric was formerly employed in medicine as an aromatic tonic, but its use is now solely to color ointments, tinctures, and other preparations. Though the color is fugitive, it is considerably used in dyeing; it gives a fine yellow upon silk, and is used as the basis of some greens, and upon woollens to produce some shades of brown. It forms an important ingredient in curry powder (see CURRY), and is much used to color varnishes (see LACQUER). The changes produced in curcumine by alkalies and other chemical agents make it available as a test; turmeric paper, made by staining paper with a tincture of the root, is often employed in the laboratory as a useful though not very accurate test, as one acid at least produces a reaction similar to that of the alkalies. Turmeric paper touched with an alkaline solution changes from yellow to brownish red, becoming violet on drying; boracic acid produces a similar change, but the tint is orange, and when an alkali is added it turns to blue.

TURNBULL, Robert, an American clergyman, born at Whiteburn, Linlithgowshire, Scotland, Sept. 10, 1809, died in Hartford, Conn., Nov. 20, 1877. He graduated at Glasgow university, studied theology, preached for a short time in Scotland and England, and in 1833 settled in Danbury, Conn. In 1835 he became pastor of the Baptist church in Detroit, in 1837 of the South Baptist church, Hartford, Conn., in 1839 of the Boylston street (now Harvard street) Baptist church in Boston, and in 1845 of the first Baptist church in Hartford. In 1851 he received the degree of D. D. from Madison university. He published "The Theatre" (Boston, 1840); "Olympia Morata" (1842); "Vinet's Vital Christianity," translated, with an introduction and notes (1846); "The Genius of Scotland" (New York, 1847); "The Genius of Italy" (1849); "Theophany, or the Manifestation of God in Christ" (Hartford, 1851); "Vinet's Miscellanies" (New York, 1852); "Pulpit Orators of France and Switzerland" (1853); "Christ in History, or the Central Power" (Boston, 1856); and "Life Pictures, or Sketches from a Pastor's Note Book" (New York, 1857). He edited Sir William Hamilton's "Discussions on Philosophy," and was for several years editor of the "Christian Review."

TURNER, a S. E. county of Dakota, recently formed, and not included in the census of 1870; area, 648 sq. m. It is intersected by Vermilion river, and consists of fertile prairies and bottom lands. Capital, Swan Lake.

TURNER, Joseph Mallord William, an English painter, born in London, April 23, 1775, died in Chelsea, Dec. 19, 1851. His father was a hairdresser in Maiden lane, Covent Garden, and in this neighborhood the painter passed his childhood. After a year or two of schooling, during which he occupied himself more with sketching from nature than with books, he was employed by the engraver John Raphael Smith to color prints, and afterward he put in skies, backgrounds, and other accessories for architectural designs. Dr. Munro gave him and Girtin access to his collection, and bought their water-color sketches. In 1789 he became a student at the royal academy, and in 1790 he exhibited a water-color "View of the Archbishop's Palace, Lambeth." Other works depicting scenes in the neighborhood of London followed, and with each year he showed increasing power and originality. In 1793 he was engaged to illustrate Walker's "Itinerant" and the "Pocket Magazine;" and during the next five or six years he made sketches in many parts of England, besides giving lessons in drawing and devoting much time to illustrating books. In 1799 he was elected an associate of the academy, and in 1802 an academician. He had hitherto been best known as a water-color painter, and had confined himself chiefly to representations of English or Welsh scenery. He now produced in oil such subjects as "The Fifth Plague of Egypt," "The Army of the Medes destroyed in the Desert by a Whirlwind," and "The Tenth Plague of Egypt;" but these were less popular than his "Dutch Boats in a Gale," "Fishermen upon a Lee Shore in Squally Weather," or "Falls of the Clyde," which afforded a field for the display of the surpassing excellence of his representations of marine scenery and of water under all conditions. In 1802 he visited France, and commemorated his arrival there by a picture of "Calais Pier;" and thenceforth at irregular periods he made extended tours through France, Switzerland, and the Rhine land, the fruits of which appeared in numerous sketches, drawings, and finished pictures. In 1807 he was elected professor of perspective to the royal academy. His works may be divided into three periods. The first extends to 1802, and covers the time employed chiefly in painting English scenes in water colors, and in studying the works and methods of his English predecessors. The second period, from 1802 to 1829, shows the effects of foreign travel and study of the great continental masters. His desire to rival and if possible to surpass Claude Lorraine led to the publication in 1808 of his *Liber Studiorum*, the superiority of which over the *Liber Veritatis* of Claude does not however afford a fair test of the comparative merits of the two painters; Turner's studies being elaborate and careful illustrations of all the principal forms of landscape composition, while Claude's are but incidental memoranda of pictures. In further competition with Claude he painted his "Sun rising through a Mist," "Crossing the Brook," "Apuleia in search of Apuleius," "Dido building Carthage," and some others of less note; but his individuality soon broke through the shackles of mere imitation, and from 1815 he worked according to his own ideas, indifferent to the examples of preceding masters. The variety of subjects he attempted during the 12 years previous to this time exhibits the originality and audacity of his genius. Not content with the production of works like "The Shipwreck," "The Wreck of the Minotaur," and "The Snow Storm—Hannibal crossing the Alps," which presented with incomparable power the elements in their wildest fury, or like the "Edinburgh from Calton Hill" and "Falls of Schaffhausen," he ransacked Lempriere's dictionary for subjects, painted humorous pieces, such as a "Country Blacksmith disputing upon the Price charged to the Butcher for Shoeing his Pony," and even attempted sacred history, having in 1803 exhibited a "Holy Family." From 1815 his conceptions expanded with his increasing observation; and after his first visit to Italy in 1819 his style underwent a material change, light instead of dark now predominating in his pictures. His return from his second visit to Italy in 1829 begins his third period, when he employed an entirely original style. His "Bay of Baiæ," "Ulysses deriding Polyphemus," "Caligula's Palace and Bridge," "Childe Harold, or Modern Italy," "Slavers throwing overboard the Dead and Dying—Typhoon coming on," "The Fighting Téméraire towed to her last Moorings," and other works produced within this period, represent the highest efforts of landscape painting in composition, in color, and in the general vein of poetic sentiment which pervades them. The change in his style of coloring, dating from this second visit to Italy, consists in an increased diffusion of light proceeding from the more illuminated parts of the landscape, and forming a bluish haze which contrasts too strongly with the surrounding portion in shadow. From 1833 this diffusion of light becomes more and more vertical, and from 1839 the vertical streaks are apparent in all his pictures. Every illuminated point is changed into a vertical line, the elongation being generally in exact proportion to the brightness of the light. Dr. R. Liebreich, ophthalmic surgeon of St. Thomas's hospital, London, in a lecture before the royal institution, March 8, 1872, attributes this change to a change in Turner's eyes, developed during the last 20 years of his life. After he reached the age of 55, Dr. Liebreich believes, the crystalline lenses of his eyes became dim, dispersed light more strongly, and consequently threw a bluish mist over illuminated objects. The aspect of nature gradually changed for him, and he reproduced what he saw. After his last visit to Italy in 1840, and during the last ten years of his life, the tendency toward brilliancy of light and color became the most marked feature of his style; and, disregarding individuality of form or local color, he made light with all its prismatic varieties the sole object of his studies. In one department of his art, that of designing from nature for illustrated works, Turner remained in the highest request until the close of his life; and in none of his productions does he appear more truly great than in his finished drawings and engraved designs. Among the most famous of these are his "Rivers of England," "Rivers of France," "England and Wales," "Scenery of the Southern Coast," and the exquisite illustrations of the poems of Rogers, Byron, Scott, and others, in all of which he shows a knowledge of landscape in its infinite variety of forms superior to that of any other artist. Fine line engravings of large size have also been executed from some of his most remarkable paintings; and, as if conscious that his reputation was destined to rest in a great measure upon this class of his works (an anticipation which has partially proved correct, as many of his pictures, owing to a careless use of pigments and varnishes, are rapidly losing their effects and crumbling to decay), he devoted much time to retouching the proofs, adding and altering the details down to the minutest twig; and all of his pictures engraved during his lifetime were executed under his own supervision. From 1790 until his death he contributed to every academy exhibition except three, sending altogether 259 pictures.—Turner never married, and exhibited an eccentricity which, whether real or assumed, subjected him to many injurious aspersions. One of his most prominent characteristics was a love of mystification, under the influence of which he worked and travelled alone, often concealed his abode for months from his most intimate friends, and died finally after a protracted absence from London in lodgings at Chelsea, where he was known under the name of Brooks, his legal adviser being the only friend acquainted with his abode. He bequeathed the bulk of his large fortune to found an asylum for decayed artists, to be called "Turner's

Gift," and such of his pictures as were in his possession to the nation. His intentions were partially thwarted by the unskilful manner in which the will was drawn; and while his pictures, drawings, and sketches have been secured to the nation, the remainder of his property, with the exception of £20,000 appropriated to the royal academy, was divided among his next of kin. The oil paintings, numbering upward of 100, and comprising specimens of his style from the outset to the termination of his career, are in the national gallery. Two of them, "The Building of Carthage," which he esteemed so highly that he is said to have announced his intention of being buried in it, and "Sun rising through a Mist," he directed should be hung next to prominent works by Claude. The drawings, studies, and sketches, numbering altogether upward of 19,000, have been cleaned, mounted, and arranged by Mr. Ruskin. Turner wrote a poem in blank verse entitled "The Fallacies of Hope," extracts from which, for the most part "destitute of rhyme, rhythm, or reason," were frequently appended to the titles of his pictures in the royal academy catalogues.—The prominent position which Turner occupies is largely due to John Ruskin, whose "Modern Painters" contains an exhaustive analysis of his works. His remains were buried in the crypt of St. Paul's, beside those of Reynolds, and his statue by McDowell was erected in the cathedral in 1863. The only extended biography of Turner is by Walter Thornbury (2 vols., London, 1862; new ed., 1874).

TURNER, Samuel Hulbeart, an American clergyman, born in Philadelphia, Jan. 23, 1790, died in New York, Dec. 21, 1861. He graduated at the university of Pennsylvania in 1807, studied theology, and was ordained deacon in the Protestant Episcopal church, Jan. 27, 1811. He became rector of the church at Chestertown, Md., in 1812, resigned in 1817, and officiated for a time in New York and Brooklyn. In 1818 he was elected professor of historic theology in the general theological seminary in New York, and in 1821 of Biblical learning and the interpretation of Scripture. From 1830 he was in addition professor of Hebrew in Columbia college. He published "Notes on the Epistle to the Romans" (1824); "Companion to the Book of Genesis" (1841); "Biographical Notices of Jewish Rabbis" (1847); "Parallel References of the New Testament" (1848); "Essay on our Lord's Discourse at Capernaum" (1851); "Thoughts on Scriptural Prophecy" (1852); commentaries on Romans, Hebrews, Ephesians, and Galatians (1852–'6); "Teachings of the Master" (1858); "Spiritual Things compared with Spiritual" (1859); "The Gospels according to the Ammonian Sections and the Tables of Eusebius" (1861); and, in conjunction with Bishop Whittingham, "Introduction to the Old Testament," from the Latin and German of Jahn (1827), and "Introduction to Sacred Philology and Interpretation," from the German of Planck (1834). His "Autobiography" was published in 1862.

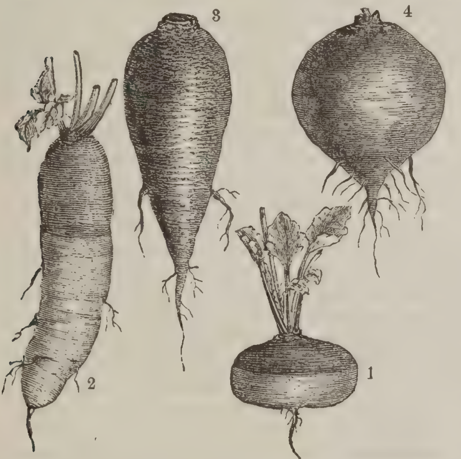
TURNER. I. Sharon, an English historian, born in London, Sept. 24, 1768, died there, Feb. 13, 1847. He was an attorney, but retired from business in 1829. His most important works are a "History of the Anglo-Saxons" (4 vols. 8vo, 1799–1805; 7th ed., revised by his son Sydney, 3 vols. 8vo, 1852), and a "History of England in the Middle Ages, with a Continuation to the Death of Elizabeth" (5 vols. 4to, 1814–'29). He also published "Inquiry concerning the Early Use of Rime" (1802); "Sacred Meditations by a Layman" (1810); "A Prolusion on the Recent Greatness of Britain, and other Subjects" (1819); "A Sacred History of the World, as displayed in the Creation and subsequent Events to the Deluge" (3 vols. 8vo, 1832 *et seq.*); and "Richard III., a Poem" (1845). **II. Sydney,** an English clergyman, son of the preceding, born April 2, 1814. He graduated at Trinity college, Cambridge, in 1836, and in 1838 became superintendent of the reformatory school of the philanthropic society in London, and effected its reorganization as the Red Hill reformatory near Reigate in 1846. In 1857 he became inspector of reformatories in England and Scotland. He has published "Reformatory Schools, a Letter to C. B. Adderley, Esq., M. P." (8vo, 1855), and an enlarged edition of his father's "Sacred History of the World."

TURNER, William, an English naturalist, born in Morpeth, Northumberland, about 1515, died July 7, 1568. He studied medicine and divinity at Cambridge, took part in the religious discussions of the time, and was imprisoned. After his release he studied natural history at Zürich and Bologna. Upon the death of Henry VIII. he returned home, and in the reign of Edward VI. became physician to the protector Somerset, and later prebendary of York, dean of Wells, and canon of Windsor. He again lived abroad during the reign of Mary. The work on which his reputation rests is his "Herball," the first book of which appeared in London (fol., 1551), and the second at Cologne (1562). He wrote also *Avium Præcipuarum, quarum apud Plinium et Aristotelem Mentio est, Historia* (8vo, Cologne, 1554), and the account of British fishes in Gesner's *Historia Animalium;* and published a collation of the English Bible with the Hebrew, Greek, and Latin copies.

TURNHOUT, a town of Belgium, in the province and 25 m. E. N. E. of the city of Antwerp; pop. about 15,000. It has a large church and extensive manufactories of linen, ticking, and lace. Leeches are reared here. In 1597 Maurice of Nassau routed the Spaniards here with the assistance of English troops, and compelled the fortress of Turnhout to surrender.

TURNING, the art of shaping wood, metal, or other hard substances into forms having usually curved, and most commonly circular outlines, and also of executing figures composed of curved lines upon plane or cylindrical surfaces, by means of appropriate tools and a machine called a lathe. Theodore of Samos, named by Pliny as the inventor of turning, may have originated the application of the process to the shaping of hard substances. The principle of turning is simple. A piece of wood or other hard substance being so fixed in a horizontal position by pivots or otherwise at its two ends as to be allowed to revolve freely about an axis in the direction of its length, and caused to turn rapidly in this manner, while a chisel or other cutting tool is approached to the piece so as to meet it as it advances on one side, and held firmly to it, the tool will cut away from the piece at that place all the material outside of a circle whose radius is the distance of its point from the axis of motion; thus it will give to the part a circular outline, and will reduce the diameter of this circle as its point is advanced further into the material. The tool being gradually moved along the length of the turning piece, it can thus be made to reduce successively the entire length to the circular outline, and, by cutting to different depths in different parts, to produce a turned piece marked with circular grooves, or other forms of curved surface. Outside circular turning is the most common, and is known as "centre work." With lathes of peculiar construction the work may be turned hollow, or bored or reamed, or turned both inside and out.—The most simple lathe for wood turning is called the pole lathe, made of two horizontal and parallel planks or beams, having a narrow space between them in which there are two uprights or puppets, one stationary, at the end of the bed, the other having a tenon passing through the space and secured by a wedge beneath, so as to be movable along the bed, to accommodate it to the length of the work. Near the upper end of each puppet, on the sides facing each other, is a conical iron or steel point, the two being in the same line. The piece is placed between the points, and the movable puppet brought up so that both points are pressed slightly into its ends; the line between these is the axis about which the piece will revolve. The fixed rest is placed conveniently for steadying the tool; while to turn the work, a groove being cut about it, usually at the left end, a stout cord or catgut is passed twice or oftener about the piece, then drawn straight and attached below to a treadle to which the workman's foot is applied, and above to an elastic pole or lath fixed at one end to the ceiling overhead, whence, probably, the name pole lath, or simply lath, or lathe. The workman holds the gouge or chisel to the work, and pressing down the treadle with his foot, the work is caused to spin rapidly round toward the point of the tool; and so long the latter takes effect. When the treadle, having come quite down, is released by the foot, the recoil of the lath carries back the cord and work in the reverse direction, and the tool does not cut. If it is required to turn the entire length of the piece, the cord must be shifted after a time to the finished part. This contrivance serves for ordinary wood turning; but on account of its imperfections, and especially the loss of time during the return or rising of the treadle, it is now little used. For light or fine work, the pole is often replaced by an elastic bow and string overhead, the cord giving the revolution being attached to the middle of the string. But the forms now more usual, and especially for heavy work, are: 1, the foot lathe, in which the treadle is by a link made to give motion to a crank, from a larger grooved wheel upon which a cord crosses in form of an 8 to a smaller grooved wheel or pulley fixed upon an axis at one end of the work, and giving motion to it; 2, the hand-wheel lathe, in which the power is applied by the action of one or two persons in turning a wheel, from which a band communicates movement to the axis and work; and 3, the power lathe for the heaviest work, moved by horses, water, or steam. Any wooden lathe, such as is used by turners in wood, is also distinguished as a bed lathe; while those of iron, for the best work in metals, are called bar lathes. In any form of lathe such as those now considered, the turning axis at one end of the work, to receive the power and give motion to the piece, in place of the simple point which can be used in the pole lathe, becomes indispensable. This axis is called the mandrel, and sometimes the "live spindle." The chucks, or contrivances fixed upon the end of the mandrel, are of various forms and construction, according to the kind of work they are intended to secure; the most common being the screw chuck, the hollow, drill, universal, concentric or die, and ring chuck, and the carrier and driver. The crowning improvement in the adaptation of the lathe to accuracy of work, and to that of all varieties, is attained through the invention of the slide rest, a carriage upon which the tool is supported, and by the construction of which it can be moved along the work by the machine or by hand, and at the same time advanced toward it, or set at any angle, as the character of the work may require.—In the cases thus far considered, there is but one axis or centre line of the work, that is, the centre line is a fixed direction throughout the process of cutting. But it is desirable to execute work in which the cutting in different parts or moments shall be in reference to two or more different axes through the solid or surface acted upon. A simple mode of effecting this is that of fixing the work successively with the different axes, and turning it at two or more operations. But practically, a far more complete and satisfactory result is attained, the forms executed being variable at the pleasure of the workman, by incorporating into the lathe devices which shift the place or direction of the single axis of motion, and in a defined manner and degree, while the work is rotated and the tool continually acting upon it. This species of turning, with a variable centre of the work at different moments, takes several names according to the devices employed or the particular results secured, as eccentric, geometric, oval, and rose-engine turning. Such work is said to be figure-turned; and the general principle is that of employing some form of chuck which shall give an oscillation or lateral movement to the axis or the work during its revolutions, so as to insure those deviations from a simple circular application of the cutter required for the intended form or figure. The chucks employed are designated as the eccentric, the geometric, the oval, or more properly elliptical, and as rosettes; while a straight line chuck can also be employed to cut plane surfaces or square work. In all work of this character, the amateur turner prides himself not only on the delicacy and elegance of his results, but quite as much on the difficulty of execution; and the value of turned work is often estimated by the degree in which it departs from the circular figure. For eccentric turning, a single eccentric chuck is one fixed upon a strong plate that can slide laterally within straight guides screwed upon the face of the mandrel, and which, having upon it a toothed wheel and click, is called the click plate; the slide, and the nose upon it for carrying the work, can be shifted into various positions out of centre, before applying the cutter. In the double eccentric chuck, a second plate or slide at the back of the first, and at right angles to it, can further vary the position of the axis. By aid of such a chuck, any required part of a disk can be brought in line with the centre of the mandrel, and holes bored in any part of it, or the edges hollowed out in curves of like or different radii, or polygons with curvilinear sides accurately produced. Ornamental work with these chucks consists mostly in the execution of variously curved figures on surfaces, without cutting away or changing the general outline, as in ornamenting ivory or fine work in wood. The ivory turner often employs a small instrument called an eccentric cutter, in which the tool revolves rapidly, being moved by a bow, and with which, by means of a single eccentric chuck and a separate adjustment of the cutter, involved figures like those ordinarily requiring the double eccentric chuck are produced. For geometric turning, a chuck of similar name is employed. In this, a wheel concentric with the mandrel, while the latter and the chuck revolve, gives, by means of a train of smaller wheels, an independent movement to the click plate and axis of the work. By varying the relative sizes of the wheels, by introducing an added wheel to cause the work to turn at the same time in a direction the reverse of that of the mandrel, and by changing the position of the tool, or giving movement at the same time to it, an almost infinite variety of curiously involved curved figures may be engraved or marked upon a plane surface to which motion is thus imparted under the point of the tool. By this machine some of the most perfect rosettes and other lathe work of bank notes, in the United States largely relied on as a means for the prevention of successful counterfeiting, are executed. The figures will vary with the construction of the machine; of which, save by actual inspection or model, no duplicate can be constructed. The geometric lathe of the American bank-note company of New York, the single one of its kind, is a foot lathe of highly complicated and perfect workmanship, the construction of which is said to have occupied three years' time, at a cost of $10,000. Elliptical turning is accomplished by means of the elliptical or oval chuck, in which the pressure of an eccentric ring, moving within and clasped by rubbers, is made to draw the slide out of centre alternately in the opposite directions, so that a stationary tool, held to a plate to which this movement is imparted during a revolution of the mandrel, will describe an ellipse instead of a circle; while the size, direction, and form of the ellipses can also be varied; and, as in the other forms of lathe here described, the micrometer screw may be introduced for determining the accuracy of proportions in the work.—Of the few machines which have been invented for turning irregular forms, in heavy or ordinary work, that of Blanchard is perhaps the best known and most successful. The principle of this machine is, that forms are turned by a pattern the exact shape of the object to be produced, which in every part of it is successively brought in contact with a small friction wheel; this wheel precisely regulates the motion of chisels arranged upon a cutting wheel acting on the rough block, so that as the friction wheel successively traverses every portion of the rotating pattern, the cutting wheel pares off the superabundant wood from end to end of the block, leaving a precise resemblance of the model. This remarkable machine, with modifications and improvements, is in use in the national armories as well as in England, and in various forms is applied to many operations in making musket stocks, such as cutting in the cavity for the lock, barrel, ramrod, butt plates, and mountings, comprising, together with the turning of the stock and barrel, 13 different machines. Besides gun stocks, it is also applied to a great variety of objects, such as busts, shoe lasts, handles, spokes, &c.—For further information respecting the tools and materials used in turning, see Holtzapffel's "Turning and Mechanical Manipulations" (3 vols., London, 1847–'52); and for the general subject, see the article "Lathe" in "Appletons' Dictionary of Machines," &c. (New York, 1857), and Valicourt's *Nouveau manuel complet du tourneur* (3 vols., Paris, 1848–'53).

TURNIP, a variety of *brassica campestris*, having two very marked forms: one with small root, but abundant stems and leaves, cultivated for its foliage and its oleiferous seeds, as rape; the other with a large, fleshy root, and comparatively little foliage, which is important in agriculture, and presents numerous subvarieties, all included under turnip. The genus *brassica*, of the family *cruciferæ*, is described and figured under another species (see MUSTARD), and the characters of *B. campestris* are given under RAPE. Both forms of the species, rape and turnip, are recognized in the wild state, though there the root of the turnip is comparatively small; when the two are sown together, they cross very freely and produce a great number of intermediate forms; the turnip form is spontaneous in Armenia, Russia, and Scandinavia, and is a weed of cultivation in various countries. There are two very distinct classes of turnips: 1, those with the root rounded and often broader than long, and usually lobed, hairy, and rough radical leaves; these are called common, round, and English turnips, and when turnip is used by cultivators without a prefix, this kind is intended; 2, those with larger, elongated, and more solid roots, and with the radical leaves smooth and covered with a bloom, like those of the cabbage; these are known as Swedish or Russian turnips (by English farmers as "Swedes"), and more generally as ruta-bagas (Sw. *rota-baggar*, root rams). There are yellow- and white-fleshed varieties in both classes, and the exterior is often more or less colored, from rose-purple to dark violet. All are biennials, at least in cultivation, and as their roots are not perfectly hardy, they must be stored for the winter. Turnips are cultivated as a garden and as a field crop. The early garden crop is of some of the quick-growing round kinds, such as the flat Dutch; the seeds must be sown as early as the soil can be worked, as hot weather soon makes the roots spongy. The main crop in garden or field is sown later; the ruta-baga sorts require a longer season, and are sown late in June or early in July, and other varieties, according to their requirements, until early in September, and in the southern states much later. In field culture, the ruta-bagas and other large kinds are sown in drills, and kept well cultivated, while the quicker growing, smaller sorts are often sown broadcast; good crops of these are frequently obtained by sowing the seed broadcast among Indian corn, just before that crop is cultivated for the last time. Turnips, when just germinated, suffer much from the attacks of the small flea beetle (*haltica*), which are often very disastrous (see TURNIP FLY); the only remedy is to use an abundance of seed, and to sprinkle the young plants copiously with slaked lime or ashes. These, with other roots, do not occupy the important place in our agriculture that they do in that of England, our abundance of Indian corn rendering them less a necessity as winter food for animals; still their value as affording a variety is becoming more appreciated, and their culture is rapidly increasing. The ruta-baga sorts, though costing more labor to raise, are the most nutritious and the best keepers; they are preserved in cool cellars or in heaps in the open ground, the roots being stacked in pyramidal piles and covered with sufficient straw and earth to prevent severe freezing. Turnips are most valued as food for cattle and sheep; they are sliced and sometimes pulped in a machine for the purpose. In England, and in some parts of this country, turnips are fed to sheep in the field; a space is enclosed with hurdles or movable fences, and when the sheep have cleared off the turnips from this portion, the hurdles are removed to enclose another section; for swine and horses they are less valued than other roots. The amount of nutritive matter in turnips is very small; the common kinds have from 90 to 92 and the ruta-bagas about 87 per cent. of water; the albuminoids are from 1 to 1·6 per cent., and the carbohydrates vary from 5 per cent. in the common to 9 per cent. in the ruta-bagas. The leading garden sorts, besides the white Dutch already mentioned as the earliest, are: the red-top strap-leaved, the best of the flat kinds; the cow-horn, a foot long and 3 in. through, the half which grows above ground being green—also grown as a field crop; and yellow Aberdeen, purplish above and yellow below, with a yellow flesh. The white French, one of the ruta-baga kinds, has the root all below ground, is twice as long as thick, of medium size, and keeps well; though called French, its origin is unknown; it is superior to all others for the table, unless it be the sweet German, which differs only in being broader than long; both are probably strains of the same variety, differing in the shape of the root. The Teltow is a great favorite with the Germans; the root is about 3 in. long and an inch thick, with a very piquant flavor which resides in the rind;



Varieties of the Turnip. 1. Red-top Strap Leaf. 2. Cow-horn. 3. Long White French. 4. Ruta-baga.

it is valued for flavoring soups and stews. In England the list of ruta-bagas or Swedes for field culture is long, and each year adds new varieties; in this country varieties known as the improved American, Skirving's purple-top, Carter's, and Laing's ruta-bagas are the principal sorts cultivated.

TURNIP FLY, a name given to several insects of different orders, but especially to the small chrysomelian beetles of the genus *haltica* (Illig.), which attack the turnip in its various parts and stages of growth. In the genus *haltica* (Gr. ἁλτικός, skilled in leaping) the body is very convex above, oval, with short thorax and wide head; antennæ slender; hind thighs very thick and formed for leaping; surface of the body generally smooth and shining, and often prettily colored; claws notched and hooked, enabling them to keep firm hold of the leaves of plants on which they feed, especially the cruciferous vegetables, to which they are often very injurious. They are all very small, the largest not more than two lines long and one line wide; most are shining green, tinged with brown or yellowish. The turnip fly of England is the *H. nemorum* (Illig.); it devours the seed leaves of the turnip as they appear above the ground, continuing its ravages all summer; in winter it conceals itself in some dry and sheltered place, laying its eggs in spring on the leaves; the larvæ eat the soft pulpy substance, making little galleries in which they undergo their changes, and in this way are as injurious as the full-grown beetles; they are slender grubs, tapering at each end, with six legs, and become perfect insects in a few weeks, a constant succession occurring through the summer. The loss to the turnip crop from their ravages is sometimes very large. (See Turnip.) The *H. striolata* (Fabr.), the wavy-striped flea beetle of the United States, much resembles the preceding; it is less than $\frac{1}{10}$ of an inch long, shining black, with a broad, wavy, buff stripe on each wing cover, and the knees and feet reddish yellow; it is abundant on the seed leaves of the turnip and other plants early in May, in some seasons threatening to be almost as injurious as the European insect. —Among the lepidoptera, the *pontia oleracea* (Harris), potherb or white butterfly, is often called turnip fly. The wings are white or yellowish, dusky near the body; back black, and antennæ blackish with narrow white rings; the expanse of wings about 2 in. Toward the beginning of June it may be seen fluttering over turnip and cabbage beds for the purpose of attaching three or four of its eggs to the under side of the leaves; the eggs are yellowish, pear-shaped, ribbed longitudinally, and $\frac{1}{15}$ of an inch long; they are hatched in about 10 days, attain their full size of $1\frac{1}{4}$ in. in three weeks, when they are pale green, and eat irregular holes in any part of the leaf; they pass a chrysalis state of 11 days, suspended by silken threads attached to the hind feet and fore part of the body in some protected place. They are again abundant toward the beginning of August, laying eggs for a second brood, the chrysalids from which survive the winter, coming out perfect insects in May or June; the chrysalis is four fifths of an inch long. The larvæ are eaten by titmice and other insectivorous birds; the chrysalids can be collected on boards placed for them near the ground, and the butterflies are easily caught in bag nets, as they fly low and lazily. This species is rarely found S. of the latitude of New Hampshire.—Some dipterous insects, as the flower flies (*anthomyiadæ*), in the larva state infest the roots of turnips, &c., eating also the pulpy parts of the leaves and stems.

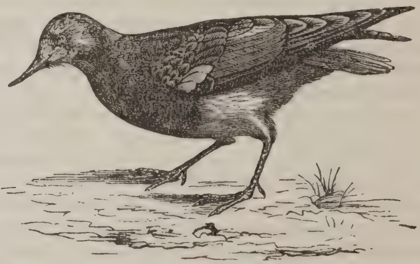
TURNSOLE. See Heliotrope.

TURNSPIT. See Terrier.

TURNSTONE, a wading bird of the oyster-catcher family (*hæmatopodidæ*) and genus *strepsilas* (Illig.), so named from its turning over by its strong bill the stones and weeds along the margins of the sea and of lakes and rivers in search of insects, mollusks, and crustaceans. The only well characterized species, *S. interpres* (Illig.), is about 9 in. long and 18 in. in alar extent; above it is irregularly variegated with black, dark rufous, and white; head and



Turnstone (Strepsilas interpres).

neck white above, with numerous spots and stripes of brownish black; in front of eyes and on throat white, usually bordered with black; lower parts, back, rump, and under wing coverts, white; quills brownish black, with white shafts; tail white at base and tip, with terminal half brownish black; conspicuous white bar on wings, bill black, and legs orange. The bill is shorter than the head, compressed, obtusely pointed, and slightly bent upward at tip; legs moderate and stout, with tarsi scaled in front; toes short and not webbed, the hind one touching the ground; wings long, the first quill longest; tail moderate and rounded. It is generally seen in small flocks of five or six, sometimes in company with various sandpipers; it is not at all shy, and emits a loud whistling note during flight; in its spring and summer dress it is very handsome; the eggs are four, 1⅓ by 1¼ in., pale yellowish green with a few black lines and irregular patches of brownish red. It is found all over the world.

TURNVEREIN. See GYMNASTICS.

TURÓCZ, a N. W. county of Hungary, bordering on the counties of Trentschin, Árva, Liptó, Zólyom, Bars, and Neutra; area, 444 sq. m.; pop. in 1870, 45,346, almost all Slovaks. It is traversed by the Carpathian mountains, and drained by the Waag and its affluent the Turócz. It abounds in rich pastures, meadows, and forests. Capital, Szent-Márton.

TURPENTINE, a term applied to several oleoresins which exude from coniferous trees, and also from the *pistacia terebinthus*, the tree called by the Greeks τερέβινθος, which furnished the principal variety known to the ancients. Of commercial turpentine there are several varieties, which consist of a resin more or less dissolved in a volatile oil, called oil of turpentine. American turpentine is chiefly obtained from the *pinus australis* or "long-leaved" pine, which is abundant on the coast of the Carolinas and Georgia; it is also obtained from "old field" pine or *pinus tæda;* the largest quantity is produced in North Carolina. Canada turpentine, called also Canada balsam and balsam of fir, is the product of *abies balsamea* or balm of Gilead fir, a small tree which grows in Canada and the state of Maine. The German turpentine is principally derived from the Scotch fir, *pinus sylvestris;* French or Bordeaux turpentine is obtained from *pinus maritima*, which grows in southern Europe and along the Mediterranean coast; Strasburg turpentine from the silver fir, *abies pectinata*, and from spruce fir, *A. excelsa.* That from silver fir is quite liquid, having the odor of lemons and a sharp, bitter taste; that from spruce fir has a strong balsamic odor and a sweetish, aromatic taste. Venice turpentine is obtained from the larch, *larix Europæa;* it is a ropy liquid, of a transparent brownish or greenish color and a bitter taste. Hungarian and Carpathian turpentines are from *pinus pumilio* and *pinus cembra.* Cyprian, Syrian, or Scio turpentine is obtained in Scio from *pistacia terebinthus*, and in Syria from *pistacia vera*, which is also the tree that furnishes pistachio nuts; it has the odor of fennel and an aromatic taste like mastic.—When exposed to the air, turpentine slowly hardens, partly from evaporation of the oil, and partly from oxidation. It softens and liquefies by heating, takes fire readily, and burns with a dense smoky flame. It is completely soluble in alcohol and ether. On boiling with water the volatile oil passes off with the steam, while the resin remains intimately mixed with a small quantity of oil and water, forming a dingy, turbid mass called "boiled turpentine." At a stronger heat the water and remaining portion of oil are expelled, and colophony remains, as a transparent resin, more or less colored. Colophony was formerly regarded as a mixture of two isomeric acid resins, pinic and sylvic acids; but recent investigations of Maly have shown it to consist mainly of abietic anhydride, $C_{14}H_{62}O_4$, which when treated with aqueous alcohol takes up water and is converted into abietic acid, $C_{14}H_{64}O_5$.—The turpentines are the sources of the oil of turpentine of commerce, which constitutes from 10 to 25 per cent. of crude turpentine. The remainder is principally rosin, from which the turpentine is distilled. (See ROSIN, and TURPENTINE, OIL OF.)

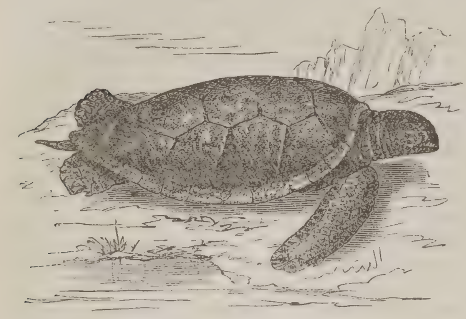
TURPENTINE, Oil of, called also spirits of turpentine, the volatile oil distilled from turpentine, and naturally contained in the wood, bark, and leaves of the trees from which it is obtained. It is prepared by distilling the crude turpentine either alone or with water. It was formerly supposed that all the oils thus obtained, which have the formula $C_{10}H_{16}$, had the same properties; but recent investigations, particularly by Berthelot, show that the oils obtained from different sources possess different physical (particularly optical) properties, and that they are generally mixtures of two or more isomeric or polymeric hydrocarbons; and furthermore, that the modifications are often produced by heat and chemical reagents during the distillation or purification of the oil. But they all belong to the class of terpenes, of which the volatile oils of aurantiaceous plants, as the orange and lemon, are members, as well as the oils of caraway, juniper, and lavender, which are isomeric; also the oils of copaiba and cubebs, which are polymeric ($C_{20}H_{32}$). These terpenes are members of a large group, designated by Berthelot as camphenes, which also have the formula $C_{10}H_{16}$. The several varieties of turpentine oil, when purified by repeated rectification with water, are colorless mobile liquids having a peculiar aromatic odor. They are insoluble in water, slightly soluble in aqueous alcohol, but dissolve in all proportions in absolute alcohol, ether, and bisulphide of carbon. They dissolve iodine, sulphur, and phosphorus, and also fixed oils and resins, on which account they are used for mixing with paints and for making varnishes. The oils of different origin vary slightly as to specific gravity and boiling point, but more particularly in regard to their optical rotatory power; but many of them are derived from several sources, and as before remarked vary when of the same origin on account of different modes of preparation. French turpentine oil, obtained from French or Bordeaux turpentine, consists of a hydrocarbon, $C_{10}H_{16}$, called by Berthelot terebenthene. It cannot be readily obtained from the commercial oil, which is too much contaminated with products of transformation, but may be obtained pure by treating French turpentine with an alkaline carbonate, and distilling it first over a water bath and then in a vacuum, by which transformation by heat or reagents is avoided. Terebenthene obtained in this way has a constant specific gravity of 0·864, a boiling point of 321·8° F., and a rotatory power of —43·3°. (See LIGHT, OPTICS, and saccharimetry in the article SUGAR.) This oil also contains an isomeric hydrocarbon, terepentilene, boiling below 356° F., and also a polymeric oil, parterebenthene, which boils at about 482°. The principal oil contained in English turpentine is australene, or austraterebenthene, having the same specific gravity and boiling point as the French oil terebenthene, but an optical rotatory power of +21·5°. The English oil also contains, according to Berthelot, an isomeric body called australene. Both the English and French oils, before their constituents are separated, possess rather less rotatory power. Venetian oil of turpentine has a rotatory power of —5·2°. All these oils possess the common property of absorbing oxygen from the air and ultimately becoming resinous, at the same time producing carbonic, acetic, and formic acids. In this gradual oxidation ozone is produced, as it is more rapidly by dipping a warm glass rod in a jar filled with vapor of turpentine; and turpentine oil exposed for some time to the sun's rays contains oxygen and ozone in solution. A paper soaked in oil of turpentine and immersed in a jar of chlorine takes fire, producing a dense black smoke and white fumes of hydrochloric acid. When treated with excess of iodine the combination takes place explosively. Turpentine oil is violently acted upon by nitric acid, often taking fire, producing nitro-benzene.—Oil of turpentine, besides being used in making varnishes, is, on account of its solvent action generally on oils and resins insoluble in water, used for discharging such substances from cloth, rags, &c. It is one of the most energetic of volatile oils. Its vapor is quickly destructive to plants and to many insects. It acts more powerfully on the lower animals than on man, easily blistering the skin of the horse. It is used in medicine as a diuretic and anthelmintic, and as a stimulant to the mucous membranes of the bowels and genito-urinary organs. It is often of great benefit in the ulcerated condition of the small intestines consequent upon typhoid fever, and also in diarrhœas. It also possesses many interesting chemical characteristics, the study of which has been of great advantage to the progress of theoretical chemistry.

TURPIN, Tulpin, or Tilpin, archbishop of Rheims, a friend and companion of Charlemagne, died Sept. 2, 800. He was originally a Benedictine monk of the convent of St. Denis, and was made archbishop about 753. His name is prefixed to a Latin chronicle, which relates the expedition of Charlemagne against the Saracens of Spain and the fight of Roncesvalles. Turpin's authorship of the chronicle is disputed, though Pope Calixtus II. in 1122 declared it to be authentic. The work is among the earliest productions relating to the events of Charlemagne's reign, and from it the tales of chivalry of the middle ages were largely taken. It was translated from Latin into French in 1206 by a clerk of Renaud, count of Boulogne. The original was first printed in the collection of Schardius (fol., Frankfort, 1566). The best editions are by Ciampi (Florence, 1822) and by Reiffenberg in *Chronique de Philippe Mouskes* (2 vols., Brussels, 1836).—See Gaston Paris, *De Pseudo-Turpino* (Paris, 1865).

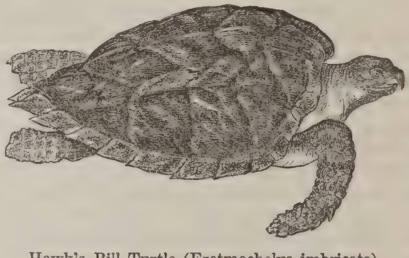
TURQUOISE, a native hydrated phosphate of aluminum, found in the mountains near Nishapur, in Khorasan, Persia, and much valued as a gem. It is called by the Persians *birusa*, and is probably the *callais* of Pliny. An inferior variety is also found at Jordansmühle in Silesia, and at Oelsnitz in Saxony. Major Macdonald discovered in Arabia Petræa, near Mt. Sinai, a variety of turquoise in a layer of red sandstone; it is darker and said to be of a finer blue than the Persian turquoise, but unfortunately it changes color, especially under the wheel of the lapidary. Persian turquoise has the chemical composition represented by the formula $2Al_2O_3,P_2O_5,5H_2O$; it is uniform and stalactitic in structure, of hardness 6 on a scale of 10; sp. gr. 2·6 to 2·8; color a peculiar bluish green to azure-blue and white, slightly translucent to opaque, with small conchoidal fracture. Specimens of a fine blue are much the most highly prized. When heated, the turquoise decrepitates strongly, gives off water, and, if colored, turns black. It tinges the blowpipe flame green, and with fluxes gives reactions of iron and copper. An analysis by Hermann of a blue oriental turquoise gave 28·9 of phosphoric anhydride, 47·45 alumina, 2·02 cupric oxide, 1·1 ferric oxide, 0·5 manganic oxide, 1·85 lime, and 18·18 water. The turquoise is much used in oriental countries for ornamenting harness, girdles, swords, amulets, and charms, and is believed to have the power of protecting its wearer against contagion, or, when he is affected with disease, of changing color and becoming pale. Several antique cameos and intaglios cut in turquoise are in the Vatican at Rome. Fragments of the gem, which appear to have been parts of amulets, are often met with in Egyptian ruins. The shah of Persia is supposed to have in his possession all the finest gems in existence, as only those of inferior quality are allowed to be taken away.

TURRETIN, or **Turretini. I. François,** a Swiss theologian, born in Geneva, Oct. 17, 1623, died there, Sept. 28, 1687. He visited Holland and France in his youth, studied under Spanheim, Morus, and Diodati, and on his return in 1647 was ordained pastor at Geneva. In 1650 he removed to Leyden, but in 1653 was recalled to Geneva to become professor of theology. His *Institutiones Theologiæ Elenchticæ* (Geneva, 1679–'85) is one of the clearest statements of Calvinistic doctrines. His complete works were published at Geneva in 1688, in 4 vols. 4to. **II. Jean Alphonse,** son of the preceding, born in Geneva, Aug. 13, 1671, died there, May 1, 1737. He was professor of ecclesiastical history at Geneva, and published *Écrits sur la vérité de la religion judaïque et de la religion chrétienne* (5 vols. 8vo), an abridgment of ecclesiastical history, &c.

TURTLE, the name popularly applied to the marine chelonian reptiles, equivalent to the suborder *chelonii* (Oppel), including the families *sphargididæ* and *chelonioidæ;* in these the dermal ossification is imperfect, and the limbs preserve through life the fingers undivided, as in the embryos of the higher families of the suborder *amydæ* or tortoises. For the characters of the order see TESTUDINATA. The word turtle in Saxon meant turtle dove, a bird and not a reptile; and the English word had the same signification until the discovery of America, when sailors gave the name of turtle or turkle to the marine chelonians of the West Indies. As distinguished from the *amydæ* (see TORTOISE), the turtles have the limbs converted into large, flattened, fin-like organs, the toes completely concealed by a common skin, the anterior pair always considerably longer than the posterior, and both frequently furnished with one or two nails on the outer margin, sometimes disappearing with age; the body is flattened to facilitate their progress through the water; swimming is performed almost entirely by the anterior limbs, the posterior moving independently and used chiefly to balance the body and guide it; the anterior are raised and depressed together very much like wings, and have a free sweep up and down and forward and backward; on land they move slowly and awkwardly by means of the front limbs, projecting them forward and dragging the body up to them, assisted greatly by the nails; the bulk of the body is forward, where are the principal muscular masses. The head and limbs cannot be retracted under the shield as in the tortoises, and the plastron is less perfectly ossified and connected with the carapace; the ribs are narrowed toward the end, and the spaces between them at this point and the bony plates of the plastron are separated by intervals filled up by cartilage; the head is flattened above, protected by large plates; the jaws are strong and firmly articulated, horny, very sharp and beak-like, and the eyes large and prominent; the head is so placed on the neck as to allow the nostrils to be easily raised above the surface, their openings being closed by a fleshy valve. Much sea water is swallowed with their food, and when the former is of necessity regurgitated the latter is retained by the numerous horny processes, pointing backward, in the œsophagus. The very young are longer in proportion to their width, and grow broader. Though lower than the tortoises, the turtles exhibit features resembling those of birds in the form of the anterior limbs, the mode of locomotion, the preponderance of the fore part of the body, bill-like jaws, and overlapping epidermic appendages. All are marine, excellent swimmers, and rarely approach the shore except to deposit their eggs; some feed entirely on sea weeds, but a few eat mollusks, crustaceans, and other aquatic animals; they are generally timid, and make but little resistance, though they are more bold and regardless of danger in the pairing season. The flesh of the herbivorous species is a wholesome food, and much sought after by epicures, while that of the carnivorous is disagreeable if not positively injurious; the callipee, or under part of the breast and abdomen, is considered the choicest part; the liver and fat are also much esteemed. They come on shore toward the end of spring to lay their eggs on the sandy beaches above high-water mark; they generally select desert islands or keys, and a still moonlight night; they dig a trench in the sand with their hind feet about 1½ ft. deep, and deposit therein about 100 eggs at each of three layings, with an interval of two or three weeks between them; the eggs are lightly covered with sand, and left to be hatched by the heat of the sun; if undisturbed, they return to the same shore year after year. They are caught on the shore, and turned on their backs, a position from which they cannot escape, owing to the flatness and width of the shell; they are harpooned and taken in nets in the water, and in the Indian seas are captured by means of the *remora.* (See SUCKING FISH.)—In the *chelonioidæ* the body is widest about midway, and the vertebral column descends continuously and gently to the tail; the shoulders and hind limbs are better protected than in the other family; the shield is more or less heart-shaped, with the posterior angle not prolonged into a point extending far over the tail; all the genera are represented on the coast of the United States, and are far less rapid swimmers than the *sphargididæ.* The latter family has only the single genus *sphargis* (Merrem), showing well the inequality of the natural groups called families; the body is more conical than in the other turtles, the carapace leaving the hind legs as well as the shoulders and neck much exposed from its great contraction behind and in front; the lower parts are equally unprotected by the plastron, this with the carapace forming little more than a wide girdle around the thorax and abdomen; the skeleton is light, the paddles large and free, and everything seems arranged for rapid and long continued voyages.—The green turtle (*chelonia midas*, Schw.), sometimes attaining a length of 5 or 6 ft. and a weight of 5 or 6 cwt., received its name from the color of the delicate fat which enriches the soup and other dishes of a course of turtle. It has a short and rounded snout, and jaws acting like straight-edged shears cutting from behind forward, the upper slightly notched, the lower with a deeply serrated margin and a hook in front; shell smooth, with 13 plates, 5 vertebral and 8 lateral, not imbricated, slightly notched and serrated behind, and with 25 marginal plates; anterior limbs rounded at shoulder, covered with a tough skin and a few small plates; forearm and hand with large plates on the anterior border, smaller ones elsewhere, and an extensile fold of skin along the posterior margin; hind limbs short and flattened, covered with small plates and a larger fold of skin on the margin; a single nail to each limb; the shell is light brown, with darker lines and blotches, and sometimes with a greenish tinge; below pale yellowish white. It is abundant in the tropical waters of America, whence great numbers are carried alive to the northern states and to Europe; the West Indies are its headquarters, whence it wanders to the gulf of Mexico and the coasts of Guiana and Brazil; it is rarely found above lat. 34° N. on the Atlantic coast, and never on the shores of Europe; the Tortugas islands are a favorite resort. It browses on the turtle grass (*zostera marina*), eating the succulent part nearest the root, the rest rising to the surface and disclosing the feeding grounds to the practised eye; in confinement it will eat and grow fat upon purslane (*portulaca oleracea*); numbers are kept for a long time in pens or crawls filled at every tide. It is often seen many hundred miles from land, and is easily taken when asleep on the surface; its capture gives employment to many and food to thousands in the West Indies. (For an account of other methods of taking them, and of the manner in which the eggs are laid, see Audubon's "Ornithological Biography," vol. ii., pp. 370–'76, Boston, 1835.) During the actual laying of the eggs nothing can disturb their labors; they are hatched in eight or nine weeks. The flesh is exceedingly delicate, and wholesome in moderate quantities; the eggs of this and of all the species are also considered a delicacy. In the young the carapace is relatively narrower, and the colors of the adults vary much. As in all the species, the eggs are dropped one by one, and disposed in regular layers, during a period of about 20 minutes; they are round, 2 to 3 in. in diameter, with the external membrane flexible, very white, and containing a considerable quantity of calcareous matter; the shell of the young is soft, and affords but little protection.—The loggerhead turtle (*thalassochelys caouana*, Fitz.) has the body very wide across the shoulders; the head very large and flat, with wide mouth, the upper jaw nearly straight, and the lower hooked; shell smooth, with a keel along the median line, and a crescentic notch in the posterior border; the plates are thin and flexible, 5 vertebral and 10 lateral, not imbricated, and the marginal plates 25; each limb has two nails, corresponding to the first two fingers; the color above is light brown, sometimes with an olive tinge and often bordered with dirty yellowish; and the shield, as in the other turtles, is frequently more or less covered with barnacles, serpulæ, and other parasites. It has an extensive range on the American coast of the Atlantic, from Virginia to Brazil, and probably on the shores of Europe and in the Mediterranean; it is more common than the green turtle, and grows to 15 or 16 cwt.; it is voracious, feeding principally on mollusks, being able to crush with its powerful jaws the strongest shells; the flesh of the young is sometimes eaten, but that of the old is rank and tough; the scales are of little value, and even the eggs have a musky flavor; it is taken only for the considerable quantity of excellent burning oil which it furnishes.—The hawk's bill or imbricated turtle (*eretmochelys imbricata*, Fitz.) has a low and rather wide head, a long and narrow mouth, the upper jaw prolonged and hooked like the beak of a hawk, the lower jaw with a smaller hook, and both with serrated margins; the shell is slightly keeled, flattened and serrated behind, with five vertebral and eight lateral plates strongly imbricated or overlapping like the scales of a fish; the plastron has

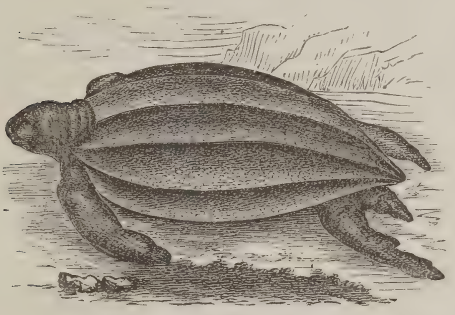


Green Turtle (Chelonia midas).



Hawk's Bill Turtle (Eretmochelys imbricata).

two keels, more or less worn off by age; there are two nails to each limb; anterior limbs very long and wing-like; the head is protected by 14 scales; the tail is conical, not extending beyond the shell. The color is yellowish above, marbled with rich chestnut brown, and yellowish white below; in the young there is a black spot on the four posterior pairs of plates. It is found in the West Indies, the gulf of Mexico, on the coasts of Guiana and Brazil, and has even strayed to the Mediterranean; the *E. squamata* (Ag.) is found in the Pacific and Indian oceans, the best being taken about the Moluccas and Papua. The food consists of sea weeds, crabs, mollusks, and fishes; in confinement it is fiercer than the preceding two; it rarely grows more than 3 ft. in length; its flesh is indifferent, and it is said unwholesome, though the eggs are good, and the species is sought after only for its beautiful horny plates, which constitute the tortoise shell of commerce. These are not considered of value unless from an animal weighing at least 160 lbs., as otherwise they are too thin; 15 lbs. of shell from a single one is a large amount, and yet in animals of the same size the imbricated would be worth 10 times as much as the green turtle. Singapore and Canton are the great marts for tortoise shell. It was consumed in large quantities in ancient Rome, even the door posts of the rich being inlaid with it; the carapace was used as a cradle and a bath tub for children, and as a shield for warriors.—The leathery or trunk turtle (*sphargis coriacea*, Merr.) is so named from having the carapace overlaid by a leathery skin instead of horny plates, smooth in the adult, but tuberculated in the young, and with seven longitudinal ridges; the head is large, narrowed in front of eyes, with small and circular nostrils, and large eyes with lids opening nearly vertically; jaws very strong and sharp-edged, the upper with three notches, the hook of the lower shutting into the central one; neck short and very thick; anterior limbs twice as long as the hind ones, the former falcate, the latter the widest; tail sharp, compressed on the sides, and not extending beyond the shell; the color is dark brown above, with lighter spots along the ridges. It is the largest of the turtles, attaining a length of 8 ft. and a weight of nearly a ton; its food consists of mollusks, crustaceans, fish, sea urchins, and marine plants; its flesh is of no value, but its shell has been used along the Mediterranean for making small boats, drinking troughs for animals, and children's bath tubs. It is found on both sides of the Atlantic, especially in the tropics, coming north as far as Massachusetts bay, and following the Gulf stream across the Atlantic to the coasts of Europe and the Mediterranean; those of E. Asia and S. Africa may perhaps be a different species; none of this genus have nails on the limbs. It was known to the ancients.—The marine species have great tenacity of life under mutilation and deprivation of food. Turtles are found as far back as the Jurassic period, continued through the cretaceous, becoming more abundant and advancing further north than at the present day, though they were not so large as the existing species; in the limited strata of the eocene clay of the island of Sheppey more species have been discovered than now exist; large species have been found in the tertiary of South Carolina and the greensand of New Jersey, of several genera.



Trunk Turtle (Sphargis coriacea).

TURTLE DOVE, the common name of several small pigeons, especially of the genera *turtur* and *œna*, characterized by a smaller size than the domestic pigeon, weaker bill, longer toes (the inner exceeding the outer), and a longer and wedge-shaped tail; they are both arboreal and terrestrial, feeding on the ground, but roosting and nesting in trees. The word turtle signified a dove until the discovery of America, when it was applied to the marine tortoises. In the genus *turtur* (Selby) the bill is slender and straight, with the tip slightly arched and acute; wings long, the second and third quills the longest; tail moderate, rounded or even; tarsi almost as long as the middle toe, for the most part naked, and the toes long and slender. There are more than a dozen species, found in various parts of Europe, India, and Africa, in woods and jungles, making their presence known by their pleasant cooing; from Europe they migrate to the south in winter; they are generally seen in flocks of about 20, in open cultivated districts, feeding on grain, seeds of grass, &c.; the nest is made in thick woods, of small twigs loosely put together, and the eggs are two. The common European turtle dove (*T. auritus*, Selby) is 11 in. long; the head, neck, breast, and back are wood-brown tinged with pearl-gray; a patch of black feathers margined with white on each side of the neck; scapulars and wing coverts black, shading into grayish, and edged with buff; lower parts white, as are the tips of the tail feathers except the two middle ones. It arrives in temperate Europe in May, leaving at the end of summer; it is found also in Asia and Africa, and is only a rare visitor to Great Britain; it has been supposed to be the origin of some of the smaller partly domestic varieties which are kept only in aviaries. The collared turtle dove (*T.*

Collared Turtle Dove (Turtur risorius).

Carolina Turtle Dove (Zenaidura Carolinensis).

risorius, Selby) is 10 in. long; the general colors are different shades of pale wood-brown, with even paler edgings, tinged with vinaceous on the under parts, and with a half collar of black on the hind neck. It is found wild in most parts of Africa, but is now widely distributed as a cage bird. If left at liberty, it flies away, and does not seem capable of domestication like the common pigeon; in warm climates seven or eight broods are raised in a season. It is doubtless the turtle of the Scriptures, and is still numerous in Egypt and Asia Minor, deriving its specific name from a fancied resemblance of its cooing to a human laugh.—In the genus *œna* (Selby) the bill is moderate and very slender, the wings long with the first three quills nearly equal and longest, and the tail of 12 feathers, very long and wedge-shaped, with the two middle feathers narrowed. The Cape turtle dove (*Œ. Capensis*, Selby) is 10 in. long, of which the tail is more than half, the closed wings reaching to about one third the length of the tail; in the male the forehead, chin, throat, and upper breast are intense black; crown, sides of neck and body, and lesser wing coverts pale French gray; middle of abdomen white; back pale brown; wings deeper brown, with a few metallic purple spots; two black bars on the rump; middle tail feathers grayish brown, with terminal half black, and the rest bluish gray with a broad black band near the tip; bill and feet yellow. It is seen on trees bordering the rivers of S. Africa, making its nest in low bushes.—In North America is found the Carolina turtle dove (*zenaidura Carolinensis*, Bonap.), about 12¾ in. long and 17½ in. in alar extent; the bill is weak and black; the wings pointed, with the second quill the longest, and the first and third nearly equal; tail longer than the wings, much graduated and wedge-shaped, and of 14 feathers; though much smaller, it resembles the passenger or wild pigeon in its lengthened tail. It is bluish above, mixed with light brownish olive, the former purest on the crown, wings, and upper surface of tail; the rest of head, sides of neck, and under parts generally light brownish red, purplish on breast, becoming brownish yellow behind; patch of metallic purplish on the sides of neck; sides of body and under surface of wings light blue; black spots on wings, and patch of same below ears; tail above with a subterminal black bar and light tip; feet yellow; the female is smaller and less reddish below. It is found all over the United States and in Cuba, and from ocean to ocean; it is rare in the British Atlantic provinces, though common on the Columbia river. The flight is extremely rapid and long continued, but not at a great height, and accompanied by a whistling noise; it walks with ease and grace, and runs swiftly; it seldom bathes, but drinks by swallowing water in long draughts, with the bill deeply immersed; it is rather shy, and difficult to shoot from the rapid flight; 200 or 300 constitute a large flock, which scatter over so large a space that it is not easy to kill more than one at a shot, except in winter when they come near farm houses; the flesh is excellent, and great numbers are killed in the southern states in winter. In Louisiana they begin to lay by the last of March, but in New England not before the middle of May; the nest is made in any kind of tree, and is very loosely constructed; it breeds in aviaries, raising several broods in a season. The eggs are two, 1⅛ by ¾ in., equally rounded at both ends, and pure white.—None of the turtle doves commit serious depredations in the fields of grain, as they are rather gleaners than reapers. The family characters have been given under Pigeon.

TUSCALOOSA, a W. county of Alabama, intersected by the Black Warrior and Sipsey rivers; area, 1,450 sq. m.; pop. in 1870, 20,081, of whom 8,294 were colored. The surface is hilly and the soil highly fertile. Iron ore, bituminous coal, and carboniferous limestone are found. The Alabama and Chattanooga railroad traverses it. The chief productions in 1870 were 7,551 bushels of wheat, 343,569 of Indian corn, 7,718 of oats, 6,951 of peas and beans, 41,262 of sweet potatoes, 120,010 lbs. of butter, and 6,458 bales of cotton. There were 1,245 horses, 1,378 mules and asses, 2,768 milch cows, 5,418 other cattle, 6,139 sheep, and 11,046 swine; 2 manufactories of cotton goods, 1 of iron castings, 2 of stone and earthen ware, 2 flour mills, 2 tanneries, 2 currying establishments, and 1 saw mill. Capital, Tuscaloosa.

TUSCALOOSA, a city of Alabama, capital of Tuscaloosa co., and of the state from 1826 to 1846, on the left bank of the Black Warrior river, at the head of steamboat navigation, 90 m. N. W. of Montgomery; pop. in 1870, 1,689, of whom 787 were colored; in 1875, about 2,500. The Alabama and Chattanooga railroad passes within a mile. The streets are wide and well shaded. A mile above the town are the grounds of the university of Alabama. The buildings, with their contents, were burned in 1865, and have been only partially restored. In 1874–'5 the university had eight professors, besides other officers, 74 students, and a library of 4,000 volumes. The Alabama insane hospital, about a mile beyond the university, has a front of 780 ft., with extensive outbuildings and grounds. It was opened in 1860, and now has about 360 inmates. Situated at the head of the cotton-planting and at the foot of the mineral region of Alabama, Tuscaloosa is the centre of trade for a district containing rich resources, as yet but imperfectly developed. It has a considerable trade in cotton, wheat, coal, &c. There are flour mills, a shoe and leather manufactory, and an extensive cotton factory in the vicinity. It has a national bank with a capital of $56,000, two weekly newspapers, and one male and four female seminaries, one of the latter being in the old state capitol. There are five churches: Baptist, Episcopal, Methodist, Presbyterian, and Roman Catholic. The city, county, and river take their name from the Indian chief Tuscaloosa ("black warrior"), who was defeated by De Soto in the bloody battle of Mavilla, Oct. 18, 1540.

TUSCANY (It. *Toscana*), a division of central Italy, bordering on the Mediterranean, and including the provinces of Arezzo, Florence, Grosseto, Leghorn with the island of Elba, Lucca, Massa e Carrara, Pisa, and Siena; area, 9,287 sq. m.; pop. in 1872, 2,142,525. It is divided from Piacenza, Parma, and Reggio by the Ligurian Apennines, and from Modena and the Romagna by the Tuscan Apennines, beginning with Monte Cimone and extending S. E. about 80 m. (See APENNINES.) The principal rivers, besides the Tiber, the head waters of which are in the province of Arezzo, are the Arno, Cecina, and Ombrone, all flowing into the Mediterranean. The coast from the mouth of the Arno to the border of Latium is occasionally bold, but generally low and swampy, and on the south are several bays. The climate is severe in the mountains, but in the valleys vegetation is hardly interrupted; and excepting in the marshy regions, which in autumn are deserted (see MAREMME), the country is very salubrious. Grain, wine, silk, olives and olive oil, and cheese are produced in great abundance; sheep and pigs and large asses abound; woollen and silk goods and many other articles are made. The purest Italian is spoken in Tuscany, and education is advanced. The principal seaport is Leghorn. Capital, Florence.—The ancient Etruria or Tuscia comprised the present division of Tuscany and adjoining territories to the east and southeast. (See ETRURIA.) After the fall of the Roman empire it passed from the Goths to the Lombards, and Charlemagne governed it through local counts or marquises, who continued to rule, under the Carlovingians or the German emperors, and occasionally almost independently, till the latter part of the 12th century. The most celebrated of these Tuscan rulers was the countess Matilda (died 1115), who figured so conspicuously on the papal side in the struggle of Gregory VII. and his successors against the emperor Henry IV., and whose sway extended beyond the limits of Tuscany. She bequeathed her dominions to the papal see, but this bequest was disregarded by the emperors, of whom Frederick I. finally acquired Tuscany by purchase from the last marquis. Pope Innocent III. subsequently renewed the claims of Rome to the heritage of Matilda, and Tuscany, distracted by Guelph and Ghibelline feuds, was split up into numerous states, among which the republics of Florence, Pisa, Siena, and Lucca, which had long been rising into power, became the most important. After a bitter contest with Pisa and other cities, the republic of Florence became the ruling power. (See FLORENCE, and MEDICI.) Despite civil and foreign wars, the republic flourished and became celebrated in letters and art, especially under Cosmo and Lorenzo de' Medici. In 1532 Alessandro de' Medici was made duke by Pope Clement VII., with the assistance of the emperor of Germany and the king of France. After his assassination in 1537, Cosmo the Great was first appointed chief of the republic, and then assumed the title of grand duke of Tuscany (1569). His line becoming extinct in 1737, Francis, duke of Lorraine, consort of Maria Theresa of Austria, became by treaty grand duke of Tuscany as Francis II., and was subsequently elected emperor of Germany as Francis I. After his death the grand duchy was ruled by Leopold I. (afterward the emperor Leopold II.) and his son Ferdinand III. In 1799 it was invaded by the French. Napoleon created in 1801 the kingdom of Etruria, which he gave to Louis, crown prince of Parma, whose wife, Maria Louisa of Spain, succeeded him as regent. In 1808 Napoleon made his sister Elisa Bacciochi grand duchess of Tuscany. In 1814 it was occupied by the allies on behalf of Ferdinand III., who was restored in 1815, Elba and other territories being added to his dominions; and Lucca, comprised in the possessions of Napoleon's widow Maria Louisa, grand duchess of Parma, reverted to Tuscany in 1847. The grand duke Leopold II., son of Ferdinand III., was compelled to abdicate in 1859; his son and nominal successor, Ferdinand IV., was dispossessed in 1860 by Victor Emanuel, and Tuscany became part of the kingdom of Italy. (See ITALY.)—See *Storia civile della Toscana dal* 1738 *al* 1848, by Zobi (5 vols., Florence, 1853); "Tuscany in 1849 and 1859," by Mrs. Trollope (London, 1859); and *La Toscane au moyen âge*, by G. R. de Fleury (Paris, 1870).

TUSCARAWAS, an E. county of Ohio, intersected by the Tuscarawas river, one of the head streams of the Muskingum; area, 520 sq. m.; pop. in 1870, 33,840. The surface is undulating and the soil fertile. Iron ore and bituminous coal abound. It is traversed by the Ohio canal, the Tuscarawas branch of the Cleveland and Pittsburgh railroad, and the Lake Shore and Tuscarawas Valley and the Pittsburgh, Cincinnati, and St. Louis railroads. The chief productions in 1870 were 509,295 bushels of wheat, 20,520 of rye, 723,659 of Indian corn, 683,594 of oats, 18,192 of barley, 133,705 of potatoes, 496,414 lbs. of wool, 917,708 of butter, 97,112 of cheese, and 41,459 tons of hay. There were 9,188 horses, 10,077 milch cows, 11,369 other cattle, 128,301 sheep, and 20,361 swine; 3 manufactories of agricultural implements, 3 of brick, 24 of carriages and wagons, 13 of clothing, 1 of pig iron, 4 of iron castings, 13 of saddlery and harness, 3 of salt, 5 of woollen goods, 16 flour mills, 16 tanneries, 13 currying establishments, 3 breweries, 3 planing mills, and 8 saw mills. Capital, New Philadelphia.

TUSCARORAS, one of the Six Nations of Iroquois, which separated from the others at an early period, and according to tradition went southwest and then southeast to North Carolina. They were divided into seven clans, and about the year 1700 occupied 15 villages and had 1,200 warriors. In 1711 they attempted to massacre the whites, but troops were called from South Carolina, and Barnwell routed them in the battle of the Neuse, Jan. 28, 1712, killing and wounding 400. They made peace, but hostilities were soon resumed. Col. Moore marched against Nahucke, a Tuscarora fort near Snowhill, and took it March 20, 1713, capturing 800 prisoners, who were given to his Indian allies. The remaining Tuscaroras fled, most of them making their way to New York. The Tuscaroras under Tom Blunt had taken no part in the hostilities. A treaty had been made with them, Nov. 25, 1712, and Blunt was made king of all the tribe in Carolina. They were placed first on Pamlico river, and were afterward removed to the Roanoke in the present Bertie co. Those who removed to New York were well received by the Five Nations and allowed to settle at the S. E. end of Oneida lake, and were formally admitted as a sixth nation in the league. During the wars with the French the Tuscaroras served under the English. In 1766 the Carolina band leased part of their lands for 150 years, and 160 removed to New York. During the revolution they sided with congress, and some of their chiefs were commissioned as captains and lieutenants; and in 1794 the United States indemnified the tribe for losses during the war. The whole tribe in time removed from North Carolina, continuing to receive rents for their lands; but as this caused difficulties, an arrangement was made by which North Carolina in 1829 sold the reversion and paid the money to the tribe. The tribe in New York occupied a reservation on Niagara ridge given them by the Senecas and confirmed by the state of New York, and an adjoining tract purchased by them from the Holland land company. A Baptist mission and school were established among them about 1800, and they have since advanced in agriculture and the arts of civilized life. In 1874 there were 388 Tuscaroras on the reservation, and there are a number in Canada with the bands of the Six Nations who emigrated thither. The name Tuscarora means shirt wearer, and must be of comparatively recent adoption.

TUSCOLA, an E. county of the S. peninsula of Michigan, bounded N. W. by Saginaw bay and intersected by the Cass river; area, about 850 sq. m.; pop. in 1870, 13,714; in 1874, 16,998. The surface is level, the soil productive, and timber is abundant. The Detroit and Bay City railroad traverses it. The chief productions in 1870 were 116,480 bushels of wheat, 82,880 of Indian corn, 84,475 of oats, 12,610 of peas and beans, 122,102 of potatoes, 40,635 lbs. of wool, 359,136 of butter, and 14,996 tons of hay. There were 2,163 horses, 3,333 milch cows, 4,861 other cattle, 9,428 sheep, and 3,713 swine; 2 flour mills, 1 tannery, 25 saw mills, and 1 woollen factory. Capital, Vassar.

TUSCULUM. See Frascati.

TUSCUMBIA, a city and the capital of Colbert co., Alabama, on the Memphis and Charleston railroad, 2 m. S. of the Tennessee river, and about 180 m. N. N. W. of Montgomery; pop. in 1870, 1,214, of whom 450 were colored; in 1875, about 1,500. Steam navigation is interrupted at this point by Muscle shoals, around which a canal is in process of construction. Tuscumbia has a healthful and agreeable climate, and is situated in a very fertile region, with coal and iron near at hand. About the centre of the city is a large spring of pure water, giving rise to Spring creek, which flows into the Tennessee. There are two large flouring mills, to one of which a cotton gin is attached, a female seminary, a small academy, a weekly newspaper, and eight churches (five for white and three for colored people). Tuscumbia was first settled in 1816, and was incorporated under its present name in 1822. It suffered much during the civil war, but is beginning to recover.

TUSSER, Thomas, an English poet, born at Rivenhall, near Witham, Essex, about 1515, died in London about 1580. He became a chorister, and finally served as a retainer in the family of William Lord Paget. Afterward he became a farmer at Katwade (now Cattiwade) in Suffolk, where he wrote "A Hundreth Good Pointes of Husbandrie" (1557). This was the first didactic poem in the language, and in 1573 appeared as "Fiue Hundreth Points of Good Husbandry vnited to as many of Good Huswiferie" (reprinted by Dr. Mavor in 1812). Fuller says Tusser was "successively a musician, schoolmaster, serving man, husbandman, grazier, poet, more skilful in all than thriving in any vocation."

TUTUILA. See Samoan Islands.

TUXPAN, a town of Mexico, in the state and 145 m. N. W. of the city of Vera Cruz, on the river Tuxpan, 5 m. from the gulf of Mexico; pop. about 5,000. It is situated at the foot of several verdure-covered hills, with groves of mangoes, oranges, and palms in the vicinity. A surrounding tract of 400,000 acres, suitable for sugar, tobacco, and fruit plantations, belongs to a stock company. The commerce of Tuxpan is annually increasing; its most important trade is in cedar logs. In the year ending Sept. 30, 1874, 105 vessels arrived, and 109 cleared. The total imports were $71,876; exports, $175,329. A bar at the mouth of the river cannot be crossed by large vessels, but the river is navigable for small craft 60 m.

TVER. I. A central government of Russia, bordering on Novgorod, Yaroslav, Vladimir, Moscow, Smolensk, and Pskov; area, 25,223 sq. m.; pop. in 1870, 1,528,881. The surface is elevated in the south, and slopes toward the north, where it terminates in an extensive plain. The Volga rises in this goverment, and is connected with the Neva by canal. Among the numerous other rivers is the Düna. There are several lakes, the largest of which, Lake Seliger, covers 76 sq. m. The soil is inferior, and the quantity of grain raised is scarcely sufficient for home consumption. A large portion of the surface is covered with forests, principally birch, beech, and pine. The railway connecting Moscow with St. Petersburg passes through the government, and, together with its water communication with the Baltic, Black, and Caspian seas, gives it an important transit trade. **II.** A city, capital of the government, at the junction of the Tvertza with the Volga, 98 m. N. W. of Moscow; pop. about 30,000. It has a fortress, a suburb on the opposite bank of the Volga, streets and squares beautifully rebuilt after the fire of 1763, fine promenades, a female gymnasium and one for boys, a large Gothic cathedral and 30 other churches, and many private and public palaces. Tver is the chief emporium of the upper Volga, with an extensive trade. In former times it was the capital of the grand duchy of Tver, and now it is the seat of an archbishop and a governor general.

TWEED, a river of Scotland and England, which rises at Tweedshaws, at the S. extremity of Peeblesshire, 1,500 ft. above sea level, among the Lowther hills, whence it runs about 20 m. N. E., and then turning E. crosses the counties of Selkirk and Roxburgh, separates Berwickshire from the English county of Northumberland, and for the last 4½ m. of its course lies wholly within English territory. It enters the North sea at the town of Berwick. Its length is 95 m., and it drains an area of 1,870 m., more than any other Scottish river except the Tay. Its principal affluents from the north are the Biggar, Gala, Leader, and Adder, and from the south the Yarrow, Ettrick, Teviot, and Till. It is navigable only a few miles from its mouth, but is remarkable for its salmon fisheries (once worth £15,000 a year, but now much reduced) and its scenery.

TWEED, William Marcy, an American politician, born in New York, April 3, 1823, died April 12, 1878. He was a chair maker, and later in life was admitted to the bar. In 1852–'3 he was an alderman, in 1853–'5 a member of congress, in 1856 a supervisor of the city and chairman of the board, in 1856–'7 a school commissioner, from 1861 to 1870 deputy street commissioner, and from 1867 to 1871 a state senator. In April, 1870, he was appointed commissioner of the department of public works, and while he held this office he and his "ring," especially in connection with the building and furnishing of the new city court house, appropriated vast sums of public money to private use. On Oct. 28, 1871, he was arrested in a civil suit on charges of malfeasance, brought by Charles O'Conor on behalf of the people, and gave bail in $1,000,000. In November of the same year he was reëlected to the state senate, but did not take his seat. On Dec. 16 he was arrested on a criminal charge of fraud, but was released on $5,000 bail. On Jan. 30, 1873, the first of the suits was tried, and the jury disagreed. On Nov. 19 he was found guilty of fraud, and was sentenced to 12 years' imprisonment on as many different counts, and to pay a fine of $12,550. He was sent to the penitentiary on Blackwell's island, and subsequently was disbarred. On April 7, 1875, a suit was begun in the supreme court of New York on behalf of the people to recover $6,000,000 from him. These were the principal of several suits both civil and criminal brought against him. On June 15 the court of appeals decided that his further imprisonment was illegal, on the ground that the court below had exceeded its powers in its cumulative sentence, and ordered his discharge. He was then ordered to find bail to the amount of $3,000,000 in the pending civil suits, and in default of the same was sent to Ludlow street jail. He escaped on Dec. 4, 1875, but was recaptured in Spain, and remained in the Ludlow street jail till his death.

TWEEDDALE. See Peeblesshire.

TWESTEN. I. August Detlev Christian, a German theologian, born in Glückstadt, April 11, 1789, died in Berlin, Jan. 8, 1876. He studied at Kiel, and taught at Berlin, where he adopted the views of Schleiermacher. In 1814 he became professor of theology at Kiel, and soon ranked next to Claus Harms in the Lutheran church of Holstein. In 1835 he succeeded Schleiermacher at Berlin, and in 1850 became a member of the new supreme ecclesiastical council of the United Evangelical church. He was one of the chief representatives of those who strive to reconcile the views of Schleiermacher with orthodox Lutheranism. His works include *Vorlesungen über die Dogmatik der evangelisch-lutherischen Kirche* (2 vols., Hamburg, 1826-'37), and *Grundriss der analytischen Logik* (Kiel, 1834). **II. Karl**, a German author, son of the preceding, born in Kiel, April 22, 1820, died in Berlin, Oct. 14, 1870. He became connected with the judicial service, and was one of the founders of the progressive party, which in 1861 involved him in a duel with Gen. Manteuffel, in which he lost his right arm. In the same year he was elected to the Prussian chamber of deputies, and he was one of the founders of the national-liberty party and an early member of the North German Reichstag. Persecuted for advocating the fullest parliamentary freedom, he retired in 1868 after being fined. His works include *Schiller in seinem Verhältniss zur Wissenschaft* (Berlin, 1863), *Machiavelli* (1868), and the posthumous *Die religiösen, politischen und socialen Ideen der asiatischen Culturvölker und der Aegypter in ihrer historischen Entwickelung* (edited by M. Lazarus, 1873).

TWICKENHAM, a village and parish of Middlesex, England, on the left bank of the Thames, opposite Richmond, with which it is connected by a handsome bridge, about 10 m. W. S. W. of St. Paul's, London; pop. in 1871, 10,533. It is celebrated as the residence of Pope, whose villa has been destroyed; but his grotto is still standing, and his monument is in the parish church, where he was buried. Walpole's seat, called Strawberry Hill, is about 1 m. distant. At Twickenham is also Orleans house, occupied by Louis Philippe while a refugee in England before his accession to the throne, and still belonging to his family. In 1874 the large church of St. Stephen was completed, and a new quarter between the old village and Richmond bridge was added to the parish.

TWIGGS, a central county of Georgia, bounded W. by the Ocmulgee river; area, 400 sq. m.; pop. in 1870, 8,545, of whom 5,632 were colored. The surface is moderately hilly and the soil fertile. The Georgia Central railroad crosses the N. border, and the Macon and Brunswick railroad intersects the W. part. The chief productions in 1870 were 164,145 bushels of Indian corn, 18,163 of sweet potatoes, and 6,189 bales of cotton. There were 473 horses, 1,046 mules and asses, 1,172 milch cows, 2,583 other cattle, 794 sheep, and 6,991 swine; 5 flour mills, and 1 saw mill. Capital, Marion.

TWILIGHT, the faint light which appears in the sky a little before sunrise, and again for some time after sunset, the amount and duration of the light varying materially in different latitudes and at different seasons. The light is caused by the reflection of the sun's rays, when below the horizon, from the vapors and minute solid particles floating in it, and perhaps from the material atoms of the air itself. To this property of reflection possessed by the atmosphere its illumination is due beyond the direct reach of the rays proceeding from the sun, as under the shadow of clouds and behind opaque objects upon the surface, where, unless the light were directed upon some principle of general diffusion, intense darkness would prevail. So also a sudden illumination would attend the rising of the sun and instantaneous darkness accompany his setting. As the sun sets to any point upon the surface of the earth, the atmosphere above this point all around the horizon is illuminated by direct rays, and the reflection from so broad an illuminated surface brings to the earth a large amount of light; but as the dark shadow of the earth, in consequence of the continued sinking of the sun, rises higher and higher into the atmosphere at this locality, the reflected light steadily diminishes, and finally disappears when no direct rays from the sun reach the higher regions of the atmosphere above the horizontal line extended toward the sunset. By observing the time after the setting of the sun to the disappearance of the reflected rays, data are afforded upon which an approximate estimate may be made of the height of the atmosphere, or at least of that portion of the atmosphere which is capable of being illuminated in the manner above described; and it is on this method chiefly that this calculation is based. On the equator, when the sun is in the equinoctial, and apparently descending vertically, and occupying as much time below as above the horizon, the duration of the twilight is an hour and 12 minutes, or one tenth of the semicircumference, equal to 18°; whence it is concluded that such must be its depression below the horizon at any place before the twilight can end; and it is reckoned from this that the height of the atmosphere is a little over 52 m. But this cannot be otherwise than a rude approximation, the calculation proceeding on the supposition of there being but one direct reflection, whereas the rays may be reflected again and again, and no account being made of the refraction the rays must experience in their direct passage through the dense stratum of air near the surface, and entering it again when turned back from the upper strata. By a different calculation, founded on observations of the progress of the edge of the dark shadow (known till it reaches the zenith as the anticrepuscular, and afterward as the crepuscular curve), made in the pure and transparent air at the summit of high mountains, the height of the atmosphere has been found by French astronomers (whose observations are recorded in the *Annuaire météorologique de France*, 1850) to be 71·46 m. This curve they found set when the sun was 17° below the horizon. The variable length of the twilight at the same place in different seasons results from the varying declination of the sun and the consequent difference of time required to sink 17° or 18° below the horizon, as his course is vertical or more or less approaching it. Near the poles, where the sun attains at noon no great height above the horizon, it also keeps near it after disappearing each night; and if its depression does not exceed 18°, the twilight is continuous into the dawn. This is the case in some portion of the summer in all places for which the least polar distance of the sun is only 18° greater than the latitude, that is, all places in higher N. or S. latitude than 48½° (the complement of 18° + 23½°, or 41½°). At a place in 48½° N. or S. latitude, the midnight depression of the sun at midsummer amounts to 41½°, the complement of the latitude, diminished by 23½°, the obliquity of the ecliptic, that is, to 18°; and there is therefore no twilight at midnight at this the most favorable season of the year. At lower latitudes there is of course no twilight at midnight. In higher and higher latitudes, as the sun is less and less depressed below the horizon at midnight in summer, the twilight increases in brilliancy, and is finally lost during the period that the circuit of the sun is above the horizon.—A beautiful feature attending the twilight is the rich coloring of the clouds upon which the direct rays of the sun strike, and from which they are reflected in gorgeous tints, which slowly change their hues as the angle of reflection varies. This phenomenon is seen in greatest perfection in mountainous regions and over wide districts, where the air remains in a uniform condition unaffected by local causes. The presence of much moisture is also favorable for the display of the finest colors. Thus at sea, especially in the warm atmosphere of the Gulf stream, these exhibitions are of the finest character, as also over the waters of inland seas. Even when no clouds are formed, brilliantly colored bands are produced along the horizon, which change in a somewhat regular order with the continued rising or declining of the sun. These tints are due to the different powers of penetration possessed by the different rays of which white light is composed. In the same manner as the solar rays are decomposed and present different colors in passing through a piece of glass covered with smoke in layers of different thickness, these rays are also decomposed in penetrating the dense and humid lower strata of the atmosphere. A slight obstruction of this kind extinguishes the blue rays, and causes those which pass through to appear yellowish red; next to this the yellow is arrested, and the light is orange; till with further obstruction the yellow entirely disappears, and the red rays alone reach the surface.

TWISS, Sir Travers, an English jurist, born in London in 1810. He graduated at Oxford in 1840, and was professor of political economy there from 1842 to 1852, afterward of international law at King's college, London, and from 1855 to 1870 regius professor of civil law at Oxford. During the same time, after his admission to the bar, he held various offices, and in 1867 was knighted on becoming queen's advocate general, from which office he retired in 1872. His works include "Epitome of Niebuhr's History of Rome" (1837); "The Law of Nations, considered as independent Political Communities" (1861), in a revised and enlarged edition of which (1876) he maintains that the three points of the Geneva court of arbitration served only to settle a passing dispute, and are now a dead letter; "The Black Book of the Admiralty," relating to ancient maritime customs and laws (1874 *et seq.*); and *Monumenta Juridica* (3 vols., 1875 *et seq.*). The last two were published under the auspices of the master of the rolls. He has also published an annotated edition of Livy (4 vols., 1840–'41).

TWITE. See LINNET.

TWO MOUNTAINS (Fr. *Deux Montagnes*), a S. W. county of Quebec, Canada, on the N. bank of the Ottawa river, at its entrance into the St. Lawrence; area, 258 sq. m.; pop. in 1871, 15,615, of whom 13,972 were of French, 770 of Irish, 348 of Scotch origin or descent, and 416 Indians. It is watered by the rivière du Nord and rivière du Chêne, affluents of the Ottawa. Capital, Ste. Scholastique.

TYBEE, an island and sound at the mouth of the Savannah river, Georgia. The sound is more properly a bay of the Atlantic; it extends from Tybee island on the south to Hilton Head island on the north. The island is about 6 m. long and 3 m. broad. In the civil war it was occupied by the federal forces, under Brig. Gen. T. W. Sherman, Nov. 28, 1861, and Fort Pulaski was reduced by their batteries on April 10–11, 1862.

TYCHO BRAHE. See BRAHE.

TYCHSEN, Olaus Gerhard, a German orientalist, born in Tondern, Schleswig, Dec. 14, 1734, died in Rostock, Dec. 30, 1815. He was educated at Göttingen, and in 1760 became professor of oriental literature at Bützow. When the university was removed to Rostock in 1789 he was appointed chief librarian and keeper of the museum. His most important work is a journal called *Bützow'sche Nebenstunden* ("Leisure Hours at Bützow," 6 vols., 1766–'9). He is noted for his dissertations upon the rabbinical language, oriental numismatics, and epigraphy. His life has been written by Hartmann (4 vols., Bremen, 1818–'20).

TYCOON, or Shogun. See JAPAN, vol. ix., pp. 542, 543.

TYLER. I. A N. W. county of West Virginia, bordering on the Ohio river, and intersected by Middle Island creek; area, 390 sq. m.; pop. in 1870, 7,832, of whom 10 were colored. The surface is undulating or rolling, and the soil in the valleys productive. Iron ore, bituminous coal, and excellent building stone and limestone are found in great abundance. The chief productions in 1870 were 157,302 bushels of Indian corn, 41,262 of wheat, 42,480 of oats, 21,386 of potatoes, 47,969 lbs. of tobacco, 26,704 of wool, 108,080 of butter, and 4,365 tons of hay. There were 1,897 horses, 1,566 milch cows, 3,615 other cattle, 12,115 sheep, and 5,402 swine; 2 saw mills, and 2 woollen factories. Capital, Middlebourne. **II.** An E. county of Texas, bounded N. and E. by the Neches river; area, 1,130 sq. m.; pop. in 1870, 5,010, of whom 1,472 were colored.

The surface is level and the soil fertile, and timber is abundant. The chief productions in 1870 were 121,723 bushels of Indian corn, 41,580 of sweet potatoes, 13,666 lbs. of rice, and 2,236 bales of cotton. There were 1,303 horses, 10,350 cattle, 3,175 sheep, and 16,781 swine. Capital, Woodville.

TYLER, Bennet, an American clergyman, born in Middlebury, Conn., July 10, 1783, died in South Windsor, May 14, 1858. He graduated at Yale college in 1804, was pastor of the Congregational church in South Britain, Conn., from 1808 to 1822, president of Dartmouth college from 1822 to 1828, and pastor of the second Congregational church in Portland, Me., from 1828 to 1833. The controversy on the "new divinity" awakened by the writings of Dr. Taylor (see TAYLOR, NATHANIEL WILLIAM), of which he was the principal opponent, resulted in the formation of a pastoral union in September, 1833, by the Connecticut clergymen who held to Dr. Tyler's opinions, and the resolution to found a theological seminary at East Windsor, of which he was president and professor of Christian theology till his death. His principal works are: "History of the New Haven Theology, in Letters to a Clergyman" (1837); "A Review of Day on the Will" (1837); "Memoir of Rev. Asahel Nettleton, D. D." (Hartford, 1844); "Nettleton's Remains" (1845); "A Treatise on the Sufferings of Christ" (New York, 1845); "A Treatise on New England Revivals" (1846); and two series of "Letters to Dr. Horace Bushnell on Christian Nurture" (1847–'8). After his death appeared his "Lectures on Theology," with a memoir by his son-in-law, the Rev. Nahum Gale, D. D. (1859).

TYLER, John, tenth president of the United States, born in Charles City co., Va., March 29, 1790, died in Richmond, Jan. 17, 1862. He was the second son of John Tyler, who was a prominent revolutionary patriot, governor of the state from 1808 to 1811, afterward judge of the federal court of admiralty, and died in 1813. He graduated at William and Mary college in 1807, and in 1809 was admitted to the bar. Two years later he was elected a member of the legislature, and he was reëlected for five successive years. In 1816 he was elected to congress to fill a vacancy, and was twice reëlected. He voted for the resolutions of censure on Gen. Jackson's conduct during the Seminole war, and opposed internal improvements by the general government, the United States bank, the protective policy, and all restrictions on slavery. Ill health compelled him to resign before the expiration of his term. In 1823 and the two following years he was a leading member of the state legislature. In December, 1825, he was chosen governor by the legislature, and at the next session was reëlected by a unanimous vote. He succeeded John Randolph as United States senator in March, 1827, and was reëlected in 1833. In the presidential election of 1824 he had supported Mr. Crawford, who received the vote of Virginia. He however approved the choice of Mr. Adams in preference to Gen. Jackson by the house of representatives; but seeing in Adams's first message "an almost total disregard of the federative principle," he sided in the senate with the opposition to him, consisting of the combined followers of Jackson, Crawford, and Calhoun. He voted against the tariff bill of 1828, and against all projects of internal improvement. During the debate on Mr. Clay's tariff resolutions in 1831–'2, he made a three days' speech against a tariff for direct protection, but advocating one for revenue with incidental protection to home industry. In 1832 he avowed his sympathy with the nullification movement in South Carolina, and made a speech against the force bill, which passed the senate with no vote but his in the negative, Mr. Calhoun and the other opponents of the bill having retired from the chamber; but he voted for Mr. Clay's compromise bill. In the session of 1833–'4 he supported Mr. Clay's resolutions of censure upon President Jackson for the removal of the deposits, which he regarded as an unwarrantable assumption of power, although he considered the bank unconstitutional. The legislature of Virginia having in February, 1836, adopted resolutions instructing the senators from that state to vote for expunging those resolutions from the journal of the senate, Mr. Tyler resigned and returned to his home, which about this time he had removed to Williamsburg. In 1836, as a whig candidate for vice president, he obtained the votes of Maryland, Georgia, South Carolina, and Tennessee. In 1838 he was elected to the legislature by the whigs of James City co., and during the subsequent session of that body he acted entirely with the whig party. He was a delegate from Virginia to the whig national presidential convention which met at Harrisburg, Dec. 4, 1839, and was nominated for vice president with Gen. Harrison as president, and elected in November, 1840. President Harrison died just one month after his inauguration, and the administration devolved on the vice president. Mr. Tyler requested the members of the cabinet to remain in the places they held under President Harrison. Three days later he published an inaugural address, which in its indications of political principle was satisfactory to the whigs, and he at once began to remove from office the democrats appointed by previous administrations, and to fill their places with whigs. In his message to the congress which convened in extra session, May 31, 1841, he discussed at considerable length the question of a national bank, at that period a leading feature of whig policy; and he intimated to several members his desire that congress should request a plan for a bank from the secretary of the treasury. Resolutions for this purpose were adopted by both houses, and Mr. Ewing sent in a bill for the incorporation of the

"Fiscal Bank of the United States," the essential features of which were framed in accordance with the president's suggestions and in deference to his peculiar views of the institution. The bill was finally passed by congress on Aug. 6, with a clause concerning branch banks differing from Mr. Ewing's, and sent to the president, who returned it with a veto message, in which he declared the act unconstitutional in several particulars. This veto created great excitement and anger among the whigs throughout the country. The whig leaders in congress, however, made yet another effort to conciliate the president and secure his assent to their favorite measure. A bill was prepared embracing certain features supposed to be acceptable to the president, and was privately submitted to and approved by him and his cabinet, and finally without any alteration passed by the house, Aug. 23, and by the senate two weeks later; but the president, who by some communications was made to believe that the bill was framed with the object of entrapping him into an act of inconsistency, vetoed it. Very soon after the promulgation of the veto, the cabinet, with the exception of Mr. Webster, the secretary of state, sent in their resignations, and published statements of their reasons for this step, reflecting severely on the conduct of President Tyler. The president filled their places by appointing Walter Forward of Pennsylvania secretary of the treasury; John C. Spencer of New York, secretary of war; Abel P. Upshur of Virginia, secretary of the navy; Charles A. Wickliffe of Kentucky, postmaster general; and Hugh S. Legaré of South Carolina, attorney general—all of them whigs, or at least opponents of the democratic party. Before the adjournment of congress, Sept. 13, the whig members published a manifesto proclaiming that all political relations between them and the president were at an end. The course taken by Mr. Webster, though condemned by some of the whigs, was justified by the greater portion of the people on the ground of the critical condition of our relations with Great Britain on the subject of the northeastern boundary, in regard to which he was at the time engaged in negotiations with the British ministry. After a satisfactory treaty was arranged and ratified (August, 1842), Mr. Webster resigned, and was succeeded by Mr. Legaré, who died soon after. In July, 1843, President Tyler reorganized his cabinet as follows: Mr. Upshur, secretary of state; Mr. Spencer, secretary of the treasury; Mr. Wickliffe, postmaster general; James M. Porter of Pennsylvania, secretary of war; David Henshaw of Massachusetts, secretary of the navy; John Nelson of Maryland, attorney general. Messrs. Porter, Henshaw, and Nelson were democrats, and the first two were rejected by the senate when their nominations came before it. In their places the president appointed William Wilkins of Pennsylvania, secretary of war, and Thomas W. Gilmer of Virginia, of the navy, who were confirmed, Feb. 15, 1844. On Feb. 28 Mr. Gilmer and Mr. Upshur, while inspecting the steamer Princeton, were killed by the bursting of a gun, and Mr. Calhoun of South Carolina was appointed secretary of state, and John Y. Mason of Virginia secretary of the navy. Under the management of Mr. Calhoun a treaty of annexation was concluded between the United States and Texas, April 12, 1844, which was rejected by the senate. But the scheme of annexation was vigorously prosecuted by the president, and at the very close of his administration brought to a successful issue by the passage of joint resolutions by congress, approved March 1, 1845. The other most important measures of his administration were the act establishing a uniform system of proceedings in bankruptcy, passed in August, 1841, and the protective tariff law of 1842. Toward the close of Mr. Tyler's term it became evident that he had lost the confidence of the whigs without having secured that of the democrats. In May, 1844, a convention composed chiefly of officeholders assembled at Baltimore and tendered him a nomination for the presidency, which he accepted; but in August, perceiving that he had really no popular support, he withdrew from the canvass. In 1861 he was a member of the peace convention, composed of delegates from the "border states," which met at Washington to endeavor to arrange terms of compromise between the seceded states of the south and the federal government. Of this convention he was elected president, but nothing resulted from its deliberations. He subsequently renounced his allegiance to the United States, and gave his support to the confederate cause. At the time of his death he was a member of the confederate congress.

TYLER, Royall, an American author, born in Boston, July 18, 1757, died in Brattleboro, Vt., Aug. 16, 1826. He graduated at Harvard college in 1776, and studied law under John Adams. He was for a short time aide to Gen. Lincoln. In 1790 he commenced the practice of law in Guilford, Vt. From 1800 to 1806 he was chief justice of the state supreme court, and he published "Reports of Cases in the Supreme Court of Vermont" (2 vols., 1809). He was also known as a dramatist, his play "The Contrast," produced in New York in 1786, being the first American play acted by a regular company, and the first also in which an attempt was made to portray the conventional Yankee character. It was followed by "May Day, or New York in an Uproar" (1787), and "The Georgia Spec, or Land in the Moon" (1797). He also published "The Algerine Captive," a novel (2 vols., 1799).

TYLER, Samuel, an American author, born in Prince George's co., Md., Oct. 22, 1809. He was admitted to the Maryland bar in 1831, and settled in Frederick City, where he has since resided. In 1836 he contributed to the

"Princeton Review" an article on "Balfour's Inquiry," which was followed by several philosophical articles, and a volume entitled "A Discourse of the Baconian Philosophy" (1844). He has also published "Burns as a Poet and as a Man" (New York, 1848); "The Progress of Philosophy in the Past and in the Future" (1859; 2d ed., 1868); and a biography of Chief Justice Taney (1872).

TYLER, William Seymour, an American linguist, born at Harford, Pa., Sept. 2, 1810. He graduated at Amherst college in 1830, and in 1831 became a classical teacher in Amherst academy. He afterward studied at Andover theological seminary, and was licensed to preach by the third presbytery of New York city in 1836; but, being elected professor of the Latin and Greek languages and literature in Amherst college about the same time, he was not ordained till 22 years later. In 1847 the professorship of ancient languages was divided, Prof. Tyler retaining that of Greek. In 1855 he visited Europe and the East, and in 1869 Greece and Egypt. He has published "The Germania and Agricola of Tacitus" (New York, 1847); "The Histories of Tacitus" (1848); "Prize Essay on Prayer for Colleges" (1854); "Plato's Apology and Crito" (1859); a "Life of Dr. Henry Lobdell, Missionary at Mosul" (Boston, 1859); "Theology of the Greek Poets" (1867); "History of Amherst College" (Springfield, Mass., 1873); "Demosthenes De Corona" (Boston, 1874); and "The Olynthiacs and Philippics of Demosthenes" (1875); besides papers in the "Transactions of the American Philological Association," and contributions to the "Biblical Repository," "Bibliotheca Sacra," "American Theological Review," &c.

TYLOR, Edward Burnett, an English author, born in London, Oct. 2, 1832. He was educated at the school of the society of Friends, Grove house, Tottenham, and in 1871 was elected a member of the royal society. He has published "Anahuac, or Mexico and the Mexicans, Ancient and Modern" (London, 1861); "Researches into the Early History of Mankind, and Development of Civilization" (1865); and "Primitive Culture: Researches into the Development of Mythology, Philosophy, Religion, Art, and Custom" (2 vols., 1871).

TYMPANUM. See EAR.

TYNDALE, William, an English reformer, born at North Nibley, Gloucestershire, about 1484, executed at Vilvoorden, in Brabant, Oct. 6, 1536. He was educated at Oxford and Cambridge, took orders, and was tutor and chaplain in the house of Sir John Welch near Bristol. He sympathized with the reformation, and while in this family he translated the *Enchiridion Militis*, or "Soldier's Manual," of Erasmus into English. His boldness of speech induced suspicion, and he went to London, where he began his translation of the New Testament. He was soon compelled to flee again, and with the promise of an annuity of £10 from Alderman Munmouth, on condition of praying for the souls of the alderman's parents, he went to Hamburg, where for a year he gave himself to his work; thence to Cologne, where the first ten sheets of his translation were put to press; and thence to Worms, where in 1525 two editions were published anonymously. They had speedy and wide circulation. The edict of the bishop of London, forbidding under heavy penalties their use or their possession, only increased the demand. Tyndale was lampooned by Sir Thomas More in seven books of elaborate abuse, and plots were laid to arrest him, which he foiled by removing in 1528 to Marburg, where he published his work on "The Obedience of a Christian Man." In 1529 a fifth edition of the New Testament was printed; and in 1530 appeared Tyndale's translation of the Pentateuch. A new edition of the New Testament, revised and corrected, was issued at Antwerp in 1534, in which Tyndale avowed his responsibility for the work. At the instance of the English government he was arrested at Antwerp, and after 18 months' imprisonment at Vilvoorden was strangled and then burned at the stake. The works of Tyndale and Frith his assistant, collected and published after the reformation was established, were issued in London in 3 vols. 8vo in 1831, and by the "Parker Society" in 1848-'50. The translation of the New Testament was the principal model and basis of the King James version, and its diction is but little more obsolete. An edition of it was published in London in 1836, edited by George Offor (reprinted, Andover, Mass., 1837). A memorial was erected to Tyndale at Nibley Knoll, Gloucestershire, in November, 1866.

TYNDALL, John, a British natural philosopher, born at Leighlin Bridge, county Carlow, Ireland, Aug. 21, 1820. Under the guidance of his father, he received a strict religious training, and early became thoroughly conversant with the Bible. Having mastered Euclid, conic sections, and plane trigonometry, he was employed in the Irish and English ordnance surveys from 1839 to 1844. During the three succeeding years he was a railway engineer, and in 1847 he accepted a post in Queenwood college, Hampshire, which he resigned in the following year to attend the lectures of Bunsen at the university of Marburg. Here, in conjunction with Prof. Knoblauch, he undertook a series of experiments in magnetism and diamagnetism, proving the existence of a relation between the molecular constitution of matter and magnetic force, and demonstrating that the direction of greatest magnetic energy will fall in the line of greatest molecular condensation. The results of their combined investigations were embodied in a paper "On the Magneto-optic Properties of Crystals, and the Relation of Magnetism and Diamagnetism to Molecular Arrangement," published in the "Philosophical Magazine" for 1850. On graduating in 1851, he prepared a mathematical dissertation on screw surfaces (*Die Schrauben-*

fläche mit geneigter Erzeugungslinie, und die Bedingungen des Gleichgewichts auf solchen Schrauben). In the same year he removed to Berlin, where for some time he was engaged in the laboratory of Prof. Magnus. Shortly after his return to England he was elected a fellow of the royal society, and in 1852 one of the secretaries of the physical section of the British association. In June, 1853, he was appointed professor of natural philosophy at the royal institution, which office he still retains (1876). Tyndall first visited Switzerland in 1849, and in company with Prof. Huxley made a second journey in 1856, since which time he has visited the Alps every year. In the winter of 1859 he succeeded in establishing himself on the Montanvert, and determined the rate of winter motion of the Mer de Glace. With the coöperation of Dr. Frankland, he planted several thermometric stations on the slopes and summit of Mont Blanc, and made numerous observations relating to combustion at great altitudes. In 1861 he scaled the hitherto inaccessible peak of the Weisshorn, and in 1868 reached the summit of the Matterhorn, crossing it from Breuil to Zermatt. The results of his glacial investigations were published in the "Philosophical Transactions" (jointly with Prof. Huxley's) for 1858, and subsequently in "Glaciers of the Alps" (London, 1860), and "Hours of Exercise in the Alps" (1871). He opposed the views of Agassiz respecting the occurrence of laminæ in glaciers, definitely ascribing the true cause of their formation to mechanical pressure. Through the direct application of the doctrine of regelation, he arrived at a satisfactory understanding of the nature of glacial motion, proving, by carefully repeated observations on the structure and properties of ice, the inefficacy of the generally admitted plastic theory to account for that phenomenon. This discovery led to a protracted controversy with Professor (afterward Principal) Forbes of Edinburgh. (See Glacier, Ice, and Forbes, James David.) In 1863 he published "Heat considered as a Mode of Motion," which placed him in the front rank of scientific expounders. In 1866 he relieved Faraday in his duties at the Trinity house, and on the death of that philosopher in 1867 became superintendent of the royal institution. To observe the solar eclipse of December, 1870, he accompanied the British expedition to Algeria, and on his return voyage instituted a number of simple inquiries in relation to the color of the ocean. He demonstrated that the change of color frequently observed at different portions of the sea is due to the reflection of certain rays of light from the surfaces of innumerable particles of matter held in mechanical suspension at varying depths of the water's mass. Prof. Tyndall visited the United States in 1872, and delivered a course of lectures in some of the principal cities of the east, the proceeds of which, $13,000, were given to the establishment of a fund designed for promoting the study of the natural sciences in America. In the "Contemporary Review" for July, 1872, Prof. Tyndall published with commendation a letter addressed to himself, wherein the writer proposed that the efficacy of prayer should be tested by making one ward of a hospital the special object of the prayers of the faithful for a term of years, and then comparing its rate of mortality with that of other wards during the same time. This gave rise to a widespread controversy, and was popularly denominated "Tyndall's prayer test." In August, 1874, while presiding over the annual meeting of the British association, he delivered the famous inaugural known as the "Belfast Address," which was denounced as a declaration of materialism.—The labors of Prof. Tyndall, though more particularly directed toward the examination of the molecular constitution of matter, have not been confined to any special branch of physics. Between 1849 and 1856 he was mainly occupied with the prosecution of his experiments in magnetism and electricity, in the course of which he conclusively settled the question of diamagnetic or reversed polarity, the existence of which, originally asserted by Faraday, and reaffirmed by Weber in 1848, had been subsequently denied by the former. In 1859 he initiated a remarkable series of researches in radiant heat, which were extended over a period of more than ten years. The diathermancy of simple and compound gases, as well as of various vapors and liquids, was experimentally tested, and the degrees of their opacity to radiant heat determined with great precision. Dry atmospheric air, which had hitherto afforded but negative results to Melloni, was ascertained to have an absorptive power about equal to that of its main elementary components, and but a mere fraction of that of aqueous vapor; a discovery which, in its bearings on terrestrial and solar radiation, has exerted a marked influence on the progress of meteorology. The principle of the physical connection of the emission and absorption of undulations (first enunciated by Euler), which formed the basis of Angström's experiments on the radiation and absorption of incandescent solids, and which laid the foundation for the science of spectrum analysis, was applied by Tyndall to gases and vapors some time previous to the publication of Kirchhoff's more specialized generalizations respecting refrangibility. Tyndall's investigations on obscure and luminous radiations, and on the nature of calorescence, or the transmutation of heat rays, form some of the most noteworthy of his contributions to molecular physics. By means of a filter composed of a solution of iodine and the bisulphide of carbon, so constituted as to intercept all but the ultra-red rays of any luminous source of heat, he has ascertained that the visible thermal rays emanating from any particular body bear but a small ratio to the total number of thermal rays emitted by that body. He has also shown, by experiments made on his own eyes, that the calorific energy of a concentrated electric beam, capable of raising platinized platinum foil to vivid redness, and of instantaneously exploding gunpowder at an absolute dark focus, is incompetent to excite the sense of vision in the human retina. The subject of gaseous conductivity (which led to views antagonistic to those entertained by Magnus), the action of odors and colors on radiant heat, and the various laws governing acoustic and optical phenomena, have also engaged his attention. To him is due the beautiful interpretation of the azure color of the firmament, as well as of the changing tints accompanying the morning and evening twilight. (See Light.) Since 1873 his labors have been more generally related to those of the Trinity house, in connection with inquiries made into the causes which affect the acoustic transparency of the atmosphere. Prof. Tyndall is a strenuous advocate of the doctrine of evolution. His vigorous language and felicitous method of exposition have given him the highest position among scientific lecturers. Besides the works already mentioned, he has published "Mountaineering in 1861" (1862); "On Radiation" (1865); "Sound, a Course of eight Lectures" (1867; 3d ed., embracing his important observations on acoustic opacity, 1875); "Faraday as a Discoverer" (1868); "Natural Philosophy in Easy Lessons" (1869); "Notes of a Course of nine Lectures on Light" (1870); "Researches on Diamagnetism and Magne-crystallic Action" (1870); "Notes of a Course of seven Lectures on Electrical Phenomena and Theories" (1870); "Essays on the Use and Limit of the Imagination in Science" (1870); "Fragments of Science for Unscientific People" (1871); "The Forms of Water in Clouds and Rivers, Ice and Glaciers" (1872); and "Contributions to Molecular Physics in the Domain of Radiant Heat" (1872). Some of these have been translated into various European languages. His work on "Sound" has been published in Chinese at the expense of the Chinese government.

TYNE, a river of Northumberland, England, formed by the junction of the North and South Tyne, the former of which rises in the Cheviot hills, on the border between England and Scotland, and the latter in the E. part of Cumberland. These two streams unite near Hexham in the S. part of Northumberland, and the Tyne thence has a course of 35 m., generally E., to the North sea. It is navigable by vessels of 300 or 400 tons as far as Newcastle-upon-Tyne. Its principal affluent is the Derwent. The Tyne is the great outlet of the seaborne coal trade, and once possessed valuable salmon fisheries.

TYNEMOUTH, a town of Northumberland, England, on a promontory at the mouth of the Tyne, and adjoining North Shields, 8 m. N. E. of Newcastle; pop. in 1871, 38,941. It has a fine harbor in the form of a basin enclosed by rocky walls, and in the season is much resorted to for sea bathing. It has many handsome houses, and extensive rope manufactories, and holds four cattle fairs annually. There is a chalybeate spring; and in the vicinity are traces of a Roman fort, and the ruins of Tynemouth priory, founded in 625 and repeatedly rebuilt.

TYNG. I. Stephen Higginson, an American clergyman, born in Newburyport, Mass., March 1, 1800. He graduated at Harvard college in 1817, for two years was engaged in mercantile pursuits, then studied theology, and was ordained to the ministry of the Episcopal church, March 4, 1821. He preached for two years in Georgetown, D. C., and for six years in Queen Anne's parish, Prince George's co., Md. In 1829 he became rector of St. Paul's church, Philadelphia, in 1833 of the church of the Epiphany, and in 1845 of St. George's church, New York, which office he still occupies (1876). He has received the degree of D. D. from Jefferson and Harvard colleges. Dr. Tyng has published "Lectures on the Law and the Gospel" (1832); "Sermons preached in the Church of the Epiphany" (1839); "Recollections of England" (1847); "Christ is All" (1849; 4th ed., 1864); "The Captive Orphan: Esther, Queen of Persia" (1859); "Forty Years' Experience in Sunday Schools" (1860); "The Prayer Book Illustrated by Scripture" (3 series, 1863-'7); and "The Feast Enjoyed" (1868). For several years he edited the "Episcopal Recorder" and the "Protestant Churchman." **II. Stephen Higginson,** jr., an American clergyman, son of the preceding, born in Philadelphia, June 28, 1839. He graduated at Williams college in 1858, studied at the Virginia Episcopal theological seminary, was ordained on May 8, 1861, and was assistant to his father in St. George's church for two years. In 1863 he became rector of the church of the Mediator, New York, and two years later he organized a new parish in the same city, that of the Holy Trinity, which erected a new and enlarged church in 1873-'4, and of which he is still pastor (1876). He is editor of the "Working Church," a weekly journal. He received the degree of D. D. from Williams college in 1872.

TYPE (Gr. τύπτειν, to stamp), a piece of metal or wood having the form of a letter or other character in relief upon one end, used in printing. The various forms of type have been described in the article Printing, which also contains the history of their invention, the methods of their use, &c. The material of which book and newspaper types are made is an alloy known as type metal, composed of lead, antimony, tin, and sometimes copper and other metals. The metals of this alloy are combined in different proportions, to meet the different requirements of hardness, softness, tenacity, or cheapness. Lead is the chief constituent; antimony is added to compensate for the softness of the lead, tin to give toughness, and sometimes copper to give a still greater degree of tenacity. Copper is sparingly used; one per cent. of it gives to type metal a perceptible reddish tint. Type metal, although melting at a comparatively low heat, fills the mould with great solidity, and shrinks very slightly in cooling. It does not oxidize seriously when exposed to the action of air, water, ley, or ink. The durability of types has been greatly improved by the process of copper-facing, invented and patented in 1850 by Dr. L. V. Newton of New York. Through the agency of the electrotype battery (see GALVANISM, vol. vii., p. 601) a thin film of copper is deposited on the face of the type, making an efficient protection against abrasion and rapid wear.—The success of typography depends on the accuracy of the types. They must be made so that they can be combined and recombined and interchanged with the greatest facility. The page of a daily newspaper, which may contain 150,000 pieces of metal, must be truly square, as if made of one piece. The first step is the making of punches, which consists in cutting on the end of a short bar of soft steel a model for each character which will be used in the font or assortment of types. When the steel has been hardened, the punch is struck on the side of a thin bar of rolled copper, producing a reversed duplicate of the model type, which when truly squared and fitted to a mould constitutes the matrix. All the matrices of a font are made to fit one mould. The type mould consists of two firmly screwed combinations of several pieces of steel, making right and left halves, each of which is almost the counterpart of the other. These halves are immovable in the direction which determines the height or depth of the body, but are readily adjustable in the direction which determines the width of the letters, so that they can produce either l or W with no further delay than that caused by the change of matrix. At one end of the mould the matrix is fitted; at the other end is an opening through which the melted metal is injected. The founding of book and newspaper types is now done by a type-casting machine, which contains in the centre of the framework a pot of type metal kept fluid by a fire beneath. The mould is connected with the melted metal through a channel. In the pot is fitted a piston or plunger, which, receiving motion from a cam, forces the fluid metal through the channel into the mould and matrix. The metal injected, fused at low heat, and cooled by a blast of cold air, solidifies almost instantaneously. As soon as the mould receives the metal, it opens, the matrix springs backward, and a little hook throws out the type. The mould closes, the matrix falls into its seat, and the plunger injects a new supply of metal, which is again thrown out as a type. The speed of the machine is governed by the time required for cooling the metal in the mould, varying from 70 types of pica to 150 types of nonpareil in a minute. The type thrown out of the mould is usually perfect as to face, but imperfect as to body. A long piece of metal, called the jet, is attached to the foot, and must be broken off; the fracture made by this breaking must be grooved out; the corners of the body are sharp or wiry, and must be rubbed down on a grindstone. The types are then set up in rows and carefully examined, one by one, under a magnifying glass. The defective letters are thrown into the melting pot, and those approved are packed in paper, ready for the printer.—For the large displayed letters of posters, types are made of wood, usually maple or bay mahogany, and rarely of smaller size than one square inch. As these types are used only in single lines, and are kept in true line by straight strips of wood called reglet, they do not require the accuracy of body which is indispensable in metal types. Wood types are made by an ingenious application of the pantagraph, the invention of William Leavenworth of Allentown, N. J., who introduced it in 1834. A tracing point at one end of the pantagraph follows the outline of a large model letter; this tracing motion is accurately repeated at the opposite end by a rapidly revolving cutter or router, which cuts a letter of similar shape out of a block of wood. The routing tool does nearly all the work; only a few cuts of the graver are required to finish the type.—The types of all American type founderies are made to the standard height of $\frac{92}{100}$ of an inch. British types are usually of the same height, but those of founderies on the European continent are variable; some German types are nearly an inch, and Russian types are more than an inch in height. In all countries the graduations of sizes or of bodies of types has been very irregular. Pierre Simon Fournier of Paris, in 1764, proposed the first practicable system. He divided a selected body of type, then known as "Cicero," into 12 equal parts, and made one such part, which he called a typographic point, the unitary basis for determining the dimensions of every larger size. All sizes were to be even multiples of the typographic point. Fournier's system, which was adopted in France, had the serious defect of an undetermined size for the body Cicero. To remedy this defect, Didot fixed the body Cicero at $\frac{1}{72}$ part of the royal French foot, and gave all the bodies made therefrom standard numerical names, which defined the number of points belonging to each body. Didot's system is now used in nearly all type founderies on the continent, but it has the disadvantage of being based on a disused measure, the royal foot, and of being in entire disagreement with the French metrical system. It has not been adopted by any English or American type founder. In 1822 George Bruce of New York introduced in his own type foundery a new system, in which the dimensions of the bodies were determined by the rule of geometrical progression, doubling every seventh size in any part of the series of sizes, and making each size 12·2462 per cent.

smaller than the size following it. The distances between the sizes are irregular, but the dimensions of the bodies are in proper correlation. (See PRINTING, vol. xiii., p. 847.)—The matrices and moulds of the first printers were always made by goldsmiths and mechanicians, but the printers cast the types. As early as 1550 type founding was made a business entirely distinct from printing. Although types are now cast by machinery, and with improved appliances, the more important tools used in making them (the punch, matrix, and mould) are substantially the same as those used in the 15th century. Attempts have been made repeatedly to cast many types by one operation in multiple moulds, or to cut them like nails out of cold metal, but they have failed chiefly through the inability to secure accuracy of body. As the required accuracy can be produced only by casting types in an adjustable mould, it may be assumed that the inventor of the type mould was the inventor of typography. The literal translation of a tablet put up at Mentz in 1507 says that John Gutenberg was the first to make printing letters in brass. Engravings made by Amman at Frankfort in 1564, and by Moxon at London in 1683, prove that the old method of casting types by hand was that used by all type founders at the beginning of this century. The first important improvement in hand casting was made in 1811 by Archibald Binney of Philadelphia, who attached a spring lever to the matrix of the hand mould, giving it an automatic return movement which enabled the type caster to double his old performance. In 1834 David Bruce of New York attached a hand force pump to the mould, which was of great value in the casting of large types, and gave a new impetus to the making of ornamental letters. William M. Johnson of Hempstead, Long Island, invented in 1828 a type-casting machine, which was used for some years by Elihu White of New York; but it was finally abandoned on account of the porousness of the types made by it. In 1838 David Bruce, jr., patented the machine which is the basis of most of those now used in America and Europe. The making of matrices by the electrotype process instead of by punching (a process of some value in the reproduction of matrices from types, or engravings in wood or soft metal) is the only recent improvement which has been generally adopted.—Types were first made in the United States by Christopher Sower of Germantown, Pa., about 1735. He cast several fonts in German and English for himself, and perhaps for others, and the anvil on which he forged his matrices of copper is still to be seen at Germantown. Sower, a publisher of books, was prevented from printing the Bible in English by the patent then held by the university of Oxford. As there was no patent on the Bible in German, he undertook this enterprise, making types, ink, and paper for the purpose, and published the first German edition of the book in America (4to, 1743). Christopher Sower, jr., continued the business, but neither he nor his father can fairly be considered as type founders to the trade. Their type-founding material was bought by Binney and Ronaldson of Philadelphia in 1798, who were materially aided by a grant of $5,000 from the state of Pennsylvania, and by the use of type-founding implements bought by Franklin when he was minister at Paris. Mitchelson, a Scotchman, made types in Boston in 1768, but soon abandoned the business. In 1769 Abel Buell of Killingworth, a silversmith, petitioned the assembly of Connecticut for money to establish a type foundery. He made types at the Sandemanian meeting house in New Haven, but with no benefit to himself or to the printers. William Wing of Hartford, in 1805, made unsuccessful attempts to cast types in conjoined moulds. His partner, Elihu White, established a type foundery at New York in 1810, and afterward at Buffalo and Cincinnati. Robert Lothian, from Scotland, began to make types at New York in 1806. He failed, but many years afterward was succeeded by his son George. John Baine, a type founder of Edinburgh, at the close of the revolutionary war established a foundery at Philadelphia. In 1813 the printers David and George Bruce, who then had the first stereotype foundery in the United States, began business as type founders. George Bruce won a high reputation as a punch cutter and as a scientific type founder.

TYPES, Chemical, a term used to designate the characteristics of chemical substances which are supposed to have an analogous molecular architecture, or are built up of elements which, although unlike, bear a certain relation to each other, by reason of which the materials of one part of the chemical fabric may be replaced by others without altering the general structure. Thus, hydrochloric acid, HCl, may be taken as a type of the chlorides in general, which may be regarded as derived from it by substitution; as for example, chloride of potassium, KCl, when the constituents are both monatomic elements; $BaCl_2$, in which barium is diatomic, and demands two atoms of chlorine; and $SbCl_3$, in which antimony (*stibium*) is triatomic, and requires three atoms of chlorine. The history of the development of the theory of types may be briefly stated as follows: Gay-Lussac observed that wax bleached by chlorine gave up oxygen and absorbed an equal volume of chlorine. Dumas observed the same action with regard to oil of turpentine, and from other observations he was led to the conclusion that a body containing hydrogen, subjected to the action of chlorine, bromine, iodine, or oxygen, takes up an atom of such element for every atom of hydrogen removed. In 1839 he arrived at a "theory of types," which may be enunciated as follows: 1. The elements of a compound may, in numerous cases, be replaced in equivalent proportions by other elements, and by compound bodies which play the part of elements. 2. When this substitution takes place in equal numbers of equivalents, the body in which the substitution occurs retains its chemical type, and the elements which have entered into it play therein the same part as the element which has been abstracted. The chemical type included bodies containing the same number of atoms of their elements, and resembling each other in their principal chemical properties, such as chloroform, bromoform, and iodoform. But when the number of elements varied while the number of atoms of the substance remained the same, they were regarded as belonging to the same molecular type, as marsh gas, CH_4, formic acid, CH_2O_2, chloroform, $CHCl_3$, and chloride of carbon, CCl_4. Berzelius opposed this theory, holding that acetic acid and trichloroacetic acid, which Dumas regarded as belonging to the same type, did not so belong, but that acetic acid is an oxide of a radical, while trichloroacetic acid consists of oxalic acid copulated with chloride of carbon; and so of other substitution compounds. But to maintain this position it was necessary to invent many radicals for compounds which were evidently analogous; and therefore when Melsens showed that acetic can be produced from trichloroacetic acid by the action of sodium amalgam, the idea that these two bodies were not built upon the same type could no longer be maintained. Gerhardt, by the introduction of his "theory of residues," reconciled the radical and substitution or type theories by supposing that a radical can be substituted for an element in a compound without altering the type; not, however, by direct substitution, but by the formation of a body of elements from each of the bodies brought together, by which residues are formed that subsequently unite. The discovery of the alcoholic ammonia bases by Wurtz and Hofmann in 1850, by which it was shown that the hydrogen in ammonia, NH_3, may be replaced by equivalents of the radicals ethyle and methyle, favored the union of the two theories. This conclusion was still further strengthened in the same year by Williamson's explanation of the general relations of the ethers and alcohols by referring them to the type of water, H_2O. Four principal types are now recognized, which are illustrated by the union of one, two, three, and four molecules of a monatomic element respectively with another monad, dyad, triad, or tetrad, as HH, OH_2, NH_3, CH_4; and nearly all organic compounds may be regarded as formed by a combination of two or more of these types. The same compound may often be referred to different types. Thus, trichloride of phosphorus, PCl_3, may be formed from three molecules of hydrochloric acid, 3HCl, by the substitution of one molecule of the triad phosphorus for three hydrogen monads; or from one molecule of ammonia, NH_3, by the equivalent substitution of phosphorus for hydrogen.

TYPE-SETTING MACHINE. See PRINTING.

TYPE WRITERS, mechanical contrivances for writing or printing with a system of movable types instead of a pen. They involve: 1, a position movement, for bringing type to a printing point; 2, an inking device; 3, an impression movement; and 4, a device for letter and line spacing. These elements have been combined in a variety of ways. The most primitive is that in which the types are engraved on a cylindrical bar, which bar is revolved on its axis and also moved backward or forward by the hand of the operator, to present the desired type to the common printing point. This bar is then depressed, thereby delivering the impression through a saturated ribbon upon a sheet of paper wrapped around a cylinder placed at right angles with the type-carrying impression bar. To the paper cylinder a rotary and a longitudinal movement are imparted for the purpose of accomplishing the letter and line space. Nearly the reverse of this is the machine in which the types are arranged on a sliding rod or a narrow bed, and the impression is given by a bar or lever, the impression point of which is equal in size to the face of a letter. This machine was designed to form wax matrices for stereotype moulds, but can be used for printing by interposing paper and inking ribbon between the type and the impression bar. A combination of the essential elements of these two machines was patented in the United States in 1868, the types being arranged on a plate in parallel rows, and the impression given by a plunger or striker. All necessary movements in this machine are accomplished by mechanical means, the operator being simply required to move or depress a key corresponding to the letter desired to be printed. Another class of type writers may be generally described as consisting of a letter wheel or disk, on the periphery of which the types are engraved, which type wheel is revolved on its axis for the purpose of presenting the desired letter to the printing point, after which either paper or wheel is moved to give the impression. Another method of type writing is by means of a section of a globe or hemisphere, having a series of perforations from circumference to centre, in which are placed sliding plungers. On the inner end of each plunger is engraved a type, and on the outer end, upon a button or knob, the corresponding letter. These plungers are directed toward a common centre or printing point, and the paper is fed past this point to produce the letter and line space. The principal mechanical device of another type-writing machine consists of an arrangement of key levers of varying lengths, which levers are made to pass each other and present their type-bearing ends at a common printing point.—The Sholes and Glidden type writer consists of a series of swinging type bars of equal length, pivoted on the circumference of a circle, in such manner that their type-bearing ends, when brought to the printing point, will strike at the centre of the circle. By this means a series of type bars of uniform length are caused to present their type at a common printing point. The paper is fed past this point, to accomplish the letter and word spacing, by the longitudinal movement of a paper car, bearing a cylindrical platen, which platen is moved upon its axis a certain distance to accomplish the line spacing. The movement of the paper car past the printing point is effected by a spring escapement, and governed by a bale or lever which is moved by the depression of any key. Fig. 1 represents a front view of the Sholes and Glidden type writer, with working parts exposed. A saturated inking ribbon is interposed between the type and paper, and is moved automatically through the slots shown on each side of the disk.—A type writer recently invented by L. S. Crandall of New York consists mainly of a vibrating platen and paper feed arranged in connection with a series of type bars, which are provided with more than one type and operated by oscillating finger levers in such manner that, according to the backward or forward motion of the same, two adjoining types are printed on a common centre. The number of centres may be increased, in proportion to the number of types on the bars, by definite vibrations of the platen. For example, if there are six types on a bar, two of them are brought to the printing point in the manner above stated, and to utilize the remaining four one forward and one backward vibration of the platen is required. The types are placed on eight bars, arranged in the segment of a circle, and connected with eight finger cups by oscillating levers. Two thumb keys, with connecting mechanism, effect the transverse movements of the platen. The longitudinal movement of platen, for accomplishing the letter space, is by common means. This machine, being operated by the fingers without changing position of hands, may be used by the blind with facility, but the reading requires sight. In fig. 2, 1 represents a side elevation, showing the arrangement of its principal elements; 2 and 3 are detail side views of the finger lever and type bar, showing their duplex motion. The type bars A are so connected with the finger levers B, and stationary supporting arms C, that a double action may be imparted to them simultaneously with their swinging motion toward the printing points. The double action throws the lever a fixed distance in a forward or backward direction, and thereby admits the use of two types on each type bar for each printing point or centre. The double action of the type bar is produced by projecting cams or shoulders, D, which, by the forward or backward oscillation of the finger levers, are thrown into contact with corresponding projections or recesses, E F, of the fixed arm C, so as to define the extent of movement required for the coupled pair of types to strike their printing point on the platen, G.—In the "Zachos steno-phonotype reporter" the types are placed on twelve shuttle bars, according to a definite scheme, and two or more of the bars may be placed in position simultaneously. The impression is given by a plunger or platen common to all the shuttle bars. By his scheme any monosyllabic word of the English language may be produced at one impression.

TYPHA (Gr. τῖφος, a fen), a genus of monocotyledonous plants, growing in fenny or marshy places, in this country popularly called cat-tail, and in England bulrush (a name here given exclusively to *scirpus*) and also reed-mace. With one other genus (*sparganium*) this makes up the small family *typhaceæ*, which in a systematic arrangement is grouped with the aroids. Typhas are found in most parts of the globe. They have perennial creeping rootstocks, sessile, linear, and nerved leaves, and monœcious flowers, crowded in a spike at the end of the stem; the flowers have neither calyx nor corolla, their place being supplied by numerous long hairs; the upper part of the spike consists of stamens only, intermingled with hairs, and the lower and more dense portion is made up of minute pistils, surrounded by and closely packed in numerous brown hairs; the ovary ripens into a small one-seeded nut, upon a stalk, surrounded by the copious down of the enlarged hairs. The best known species is the common or broad-leaved cat-tail (*typha latifolia*), found all over this and nearly all other countries; it is often 8 or 10 ft. high, and in some localities occupies the marsh to the exclusion of all other vegetation. The leaves are flat, and the spike is a foot or more long, with no interval between the staminate and pistillate portions; the stamens, when they have performed their office, fall away, leaving the upper portion of the stem bare. Our only other species is the small or narrow-leaved cat-tail (*T. angustifolia*), which is much smaller; the leaves are narrower, and channelled at the base; the spikes are more slender, with usually a space, often an inch long, between the pistillate and staminate portions; the two grow together, though this is much the less common, and all the characters which distinguish them are variable. In autumn the spikes disintegrate, and in localities where the plants abound the air is annoyingly filled with the copious down. The dried down has been used in beds as a substitute for feathers; but unless the ticking is very tight, or waxed on the inside, the hairs will work through and annoy the sleeper. At present it is largely manufactured into a non-conducting covering for steam pipes and boilers. The quantity of foliage produced by these plants in favorable localities is immense, and it now nearly all goes to waste; unsuccessful attempts have been made to utilize it as paper stock. In France, where it is called *massette*, the leaves of cat-tail are used in the nurseries as a ligature in budding.

Cat-tail (Typha latifolia).

TYPHOID FEVER. See FEVERS, vol. vii., p. 167.

TYPHON, in Greek mythology, the personification of volcanic phenomena and violent winds. The common account made Typhon the son of Tartarus and Gæa, destined to revenge the defeat of the Titans by the Olympian gods. According to Pindar, his head reached to the stars, his eyes darted fire, his hands extended from the east to the west, terrible serpents were twined about the middle of his body, and 100 snakes took the place of fingers on his hands. Between him and the gods there was a dreadful war. Jupiter finally killed him with a flash of lightning, and buried him under Mt. Ætna.—For Typhon (or Set) in Egyptian mythology, see DEMONOLOGY, vol. v., p. 794, and OSIRIS.

TYPHOON. See HURRICANE.

TYPHUS. See FEVERS, vol. vii., p. 166.

TYRANT, in ornithology. See KING BIRD.

TYRE (in classical writers, *Tyrus;* in the Hebrew Scriptures, *Tzor*, rock), the wealthiest and most powerful city of Phœnicia, founded by the Sidonians, in a naturally strong position on the coast of the Mediterranean, 23 m. S. of Sidon. In later times it extended over a small adjacent island, the new part gradually becoming the more important, and the old receiving the name of Palætyrus or Old Tyre, now called Ras el-Ain. The latter is designated in the historical books of the Old Testament as the "stronghold" or "fortress" (*mibtzar*) Tzor, while, no doubt in allusion to its insular part, the city is called by Isaiah the "stronghold of the sea," and described by Ezekiel, in his glowing picture of its wealth, splendor, and maritime power, as situated "in the heart of the seas." On its site now stands a poor village called Sur. The island on which the town stood was originally severed from another small island bearing the temple of Melkart; but when the latter was rebuilt by Hiram, the little arm of the sea between the two islands was filled up, and by means of embankments toward the south the extent of the island was more than doubled. On the land thus obtained was built a new quarter of the city, which the Greeks called Eurychoron. Tyre was protected on all sides by dikes, and surrounded by fortified enclosures. Hiram built a palace in this insular town, which constantly grew in importance, while Palætyrus was neglected and became comparatively insignificant. Both parts withstood a long siege by the Assyrians (under Shalmaneser according to Josephus, but more probably under Sargon), but only that built on the island is believed to have successfully resisted a longer one by Nebuchadnezzar; while Alexander the

Great, by the construction of a mole from the mainland to the island, succeeded in reducing the whole of Tyre. This mole, gradually enlarged and strengthened by ruins and alluvial deposits, has since permanently connected the two sites of the ancient city, converting the island into a promontory. Even the ruins of the "daughter of Sidon" and mother of Carthage have mostly been covered by the sea. The burial places still testify to the existence of the ancient city. Most of the tombs are rock-cut and subterranean. They contain generally more than one chamber, in the walls of which are recesses holding embalmed corpses in coffins. There are also the ruins of a Christian cathedral, which Eusebius dedicated in 324 and describes in his ecclesiastical history. It was restored by the crusaders, and in it were placed the remains of the emperor Frederick Barbarossa. An earthquake destroyed the rebuilt town in the beginning of the 13th century. In 1874 the tract of land on which the cathedral was situated was purchased by the German government for the purpose of excavating it, and the edifice has been partly unearthed. (For the history of Tyre, see PHŒNICIA.)

Ruins of Tyre.

TYROL (Ger. also *Tirol*), a crownland or province of Cisleithan Austria, bounded N. by Bavaria, E. by Salzburg and Carinthia, S. by Italy, and W. by Switzerland; area, including Vorarlberg, 11,325 sq. m.; pop. in 1870, 885,789, nearly two thirds of German and the rest of Italian descent, and all Roman Catholics. The principal towns are Innspruck, the capital, Brixen, Trent, Bregenz (in Vorarlberg), and Botzen, the first four respectively the capitals of the four circles into which the province is divided. It is as mountainous and picturesque as Switzerland, being traversed by several chains of the Alps. The northern chain is known as the Tyrolese or German, and the southern as the Trent Alps, the latter joining on the east the Carnic Alps. The Rhætian Alps, which occupy the centre, and are the loftiest mountains in Austria, embrace the Ortlerspitze (12,800 ft.), on the confines of Tyrol, Italy, and Switzerland, terminate in the N. E. part of Tyrol; and the Gross-Glockner (about 12,500 ft. according to the latest measurements), the highest point of the Noric Alps, rises on the confines of Tyrol, Carinthia, and Salzburg. Many of the summits are above the line of perpetual snow, and more than 150 sq. m. is covered with glaciers. These chains are crossed by some of the lowest Alpine passes, the best known being the Brenner pass, traversed by the railway from Innspruck to Botzen. The Inn and Adige are the largest rivers besides the Rhine, which separates Vorarlberg from Switzerland. Lakes Constance and Garda are partly in the province, on the N. W. and S. W. borders respectively. The climate is generally severe except in the south. About one third of the whole surface is covered by perpetual snows, glaciers, and barren rocks, and an equal space by forests; the rest consists of pasture and arable land. The total value of landed property in 1870 was estimated at about 300,000,000 florins, and of cattle at 23,500,000 florins. Maize and other grain, fruit, wine, and silk are produced. Goats and sheep abound, as well as the chamois, hares, marmots, and eagles. The minerals include gold, iron, copper, lead, and coal. Lace, embroidery, gloves, hardware, and toys are made, and there is an active transit trade and general commerce. About 30,000 Tyrolese annually migrate in summer and return in autumn. The country is rich in schools, including a university at Innspruck. The Tyrolese are a fine-looking race, wearing picturesque costumes, and are noted for their national songs, piety, patriotism, and industry.—In early times the country was inhabited by Rhætian and Celtic tribes. Under the reign of Augustus it became part of Rhætia. (See RHÆTIA.) Subsequently it was occupied successively by various races, and was ultimately divided into petty states or lordships, tributary to the dukes of Bavaria, among which the duchy of Meran was the most important. These were finally united, and in 1364 were annexed to the duchy of Austria by Duke Rudolph IV., to whom Margaret, surnamed Maultasch, the heiress of Tyrol, had ceded her rights. After various changes Tyrol was inherited in 1490 by Maximilian, the future emperor of Germany, and after new changes finally reunited with the main line of the house of Austria in 1665. By virtue of the treaty of Presburg (Dec. 26, 1805), the country passed into the possession of Bavaria. This gave rise to the insurrection under Andreas Hofer in 1809, during which the women fought by the side of the men, and hundreds of them were slain. (See HOFER.) Austria recovered Tyrol in 1814. The local constitution dates from 1861. The diet consists of 68 members, including the prince-archbishop of Salzburg, whose jurisdiction extends over part of Tyrol, the two prince-bishops of Trent and Brixen, the rector of the university, 4 clerical delegates, 10 of the landholding aristocracy, 13 of large cities, 3 of chambers of commerce and industry, and 34 of rural communities. They are elected for six years. The president of the diet is appointed by the emperor. Vorarlberg has its own constitution and diet. The Tyrol diet elects 10 members to the Reichstag. The Italian or Welsh Tyrolese, who inhabit the southern districts, favor a union with Italy, but Garibaldi's attempt in 1866 to wrest these districts from Austria proved abortive. The ultramontane party preponderates excepting in some of the larger cities, and recent attempts to diminish the influence of the clergy encountered a violent opposition.—See Hormayr, *Geschichte der gefürsteten Grafschaft Tirol* (2 vols., Tübingen, 1806–'8), and *Das Land Tirol und der Tirolerkrieg von* 1809 (2 vols., Leipsic, 1845); Egger, *Geschichte Tirols von den ältesten Zeiten bis in die Neuzeit* (2 vols., Innspruck, 1872–'4); Miss R. H. Busk, "The Valleys of Tyrol" (London, 1874); H. Baden Pritchard, "Tramps in the Tyrol" (London, 1874); Steub, *Drei Sommer in Tyrol* (3 vols., enlarged ed., Stuttgart, 1875); and W. A. Baillie Grohman, "Tyrol and the Tyrolese" (London, 1876).

TYRONE, a N. county of Ireland, in the province of Ulster, bordering on Lough Neagh, which separates it from Antrim, and the counties of Armagh, Monaghan, Fermanagh, Donegal, and Londonderry; area, 1,260 sq. m.; pop. in 1871, 215,668. The chief towns are Strabane, Dungannon, and Omagh, the capital. The surface is greatly diversified, and has many fertile plains and valleys. The only considerable rivers are the Foyle and Blackwater. Coal is found, but turf is the usual fuel. The Londonderry and Enniskillen railway passes through Tyrone near Strabane.

TYRRELL, an E. county of North Carolina, bordering on Albemarle sound, and bounded E. by Alligator river; area, about 350 sq. m.; pop. in 1870, 4,173, of whom 1,302 were colored. The surface is level and the soil sandy. A large portion of the county is covered with swamps and heavy forests of pine, cypress, and red cedar; and shingles, staves, tar, and turpentine are extensively exported. The chief productions in 1870 were 105,308 bushels of Indian corn, 22,544 of sweet potatoes, 507 bales of cotton, and 17,894 lbs. of rice. There were 306 horses, 2,478 cattle, 1,539 sheep, and 4,664 swine. Capital, Columbia.

TYRTÆUS, a Greek poet of the 7th century B. C., a native of Attica or of Lacedæmon. An ancient tradition recounts that, in the second Messenian war, the Spartans were commanded by an oracle to apply to the Athenians for a leader. In answer the Athenians sent Tyrtæus, a schoolmaster of low family and reputation, and deformed, as the most unfit person they could select for the purpose; but he so inspired the Spartans with his war songs, that the Messenians were subdued. His poems were of two kinds: marching songs in anapæstic measures, to be sung with the music of the flute, and elegiac exhortations to constancy and courage. The fragments of them are in Gaisford's *Poetæ Minores Græci* (translated into English verse by Polwhele, 1786–'92), and in Bergh's *Poetæ Lyrici Græci* (3d ed., Leipsic, 1866). They have been newly collected and annotated by A. Lami (Leghorn, 1874).

TYRWHITT, Thomas, an English author, born in London, March 29, 1730, died there, Aug. 15, 1786. He graduated at Oxford in 1750, and in 1756 was appointed under secretary of war, and in 1762 clerk of the house of commons. He resigned office in 1768. Two years previous to his death he was appointed a curator of the British museum. His principal works in English are "Observations on some Passages in Shakespeare" (8vo, Oxford, 1766), and an edition of Chaucer's "Canterbury Tales," with an "Essay on his Language and Versification, an Introductory Discourse, and Notes" (5 vols. 8vo, London, 1773–'8). He aided in the publication of Chatterton's "Poems by Rowley," and supported the authorship of them by Chatterton. He also published in Latin notes, animadversions, and conjectures on writings by Plutarch, Babrius (the supposed author of Æsop's fables), Æschylus, Euripides, Aristophanes, Strabo, and others. His principal work in this department of literature was an edition of Aristotle's "Poetics," published posthumously in 1794.

TYTLER. I. William, a Scottish author, born in Edinburgh, Oct. 12, 1711, died Sept. 12, 1792. He was a writer to the signet, but his reputation rests chiefly upon his "Historical and Critical Enquiry into the Evidence produced by the Lords of Murray and Morton against Mary Queen of Scots" (Edinburgh, 1760; enlarged ed., 2 vols. 8vo, London, 1790); and he edited the "Poetical Remains of James I." (Edinburgh, 1783). **II. Alexander Fraser,** a Scottish jurist, son of the preceding, born in Edinburgh, Oct. 15, 1747, died there, Jan. 5, 1813. He was called to the bar in 1770, and became professor of universal history in the university of Edinburgh in 1786, judge advocate of Scotland in 1790, and judge of the court of session, with the title of Lord Woodhouselee, in 1802. He published a "Supplement to Lord Kames's Dictionary of Decisions to 1778" (Edinburgh, 1778; 2d ed., to 1796, 1797); "Plans and Outlines of a Course of Lectures on Universal History, Ancient and Modern" (1782); "Essay on the Principles of Translation" (1791); "England Profiting by Example" (1799); "Essay on the Military Law and the Practice of Courts Martial" (1800); "Elements of General History" (1801); "Memoirs of the Life and Writings of Henry Home of Kames" (2 vols. 4to, 1807); and "Historical and Critical Essay on the Life and Writings of Petrarch" (1810). His lectures were posthumously published under the title "Universal History, from the Creation of the World to the Beginning of the Eighteenth Century" (6 vols. 18mo, London, 1834–'5). **III. Patrick Fraser,** a Scottish author, son of the preceding, born in Edinburgh, Aug. 30, 1791, died in Malvern, England, Dec. 24, 1849. He was admitted to the faculty of advocates in 1813, and after practising law for several years devoted himself to literature. In 1844 he received a government pension of £200 a year for literary services. He published "Life of James Crichton of Cluny, commonly called the Admirable Crichton" (Edinburgh, 1819); "Life and Writings of Sir Thomas Craig of Riccarton" (1823); "Life of John Wicklyff" (1826); "History of Scotland, 1149–1603" (9 vols., 1828–'43); "Lives of Scottish Worthies" (3 vols., 1831–'3); "Historical View of the Progress of Discovery on the more Northern Coasts of America" (1832); "Life of Sir Walter Raleigh" (1833); "Life of King Henry VIII." (1837); and "England under the Reigns of Edward VI. and Mary, with the Contemporary History of Europe" (2 vols., 1839).

TZANA, or **Dembea,** a lake of Abyssinia, in lat. 12° N., lon. 37° 15′ E., in a fertile grain-producing region, 6,110 ft. above the sea. It is 50 m. long, 25 m. wide, has a depth in some places of 600 ft., and contains several islands, some of which are inhabited. It receives numerous streams, and is traversed in the S. part by the Abai, the Nile of Bruce.

TZAR. See Czar.

TZARSKOYE SELO (Rus., "the czar's village"), or **Sofia,** a town of Russia and the imperial summer residence, in the government and 15 m. S. of the city of St. Petersburg; pop. about 12,000. It grew out of a country house and park of Peter the Great. The present palace was built in 1744 by the empress Elizabeth, and embellished by Catharine II. The main façade, besides the side wings, is nearly 800 ft. long. The high walls of the banquet hall and other rooms are resplendent with gold and other precious metals. The ball rooms are among the largest and most gorgeous of the kind anywhere. One room is entirely panelled in amber; another is fitted up in Chinese fashion. The marble gallery communicating with the palace is a stupendous and brilliant structure. The palace grounds extend over a circumference of 18 m., employ 600 persons, and contain some of the most wonderful artificial and natural attractions in the world. They include a Gothic castle with Dannecker's "Christ," monuments of distinguished Russians, a pretty pavilion near the lake, and the arsenal in an English-Gothic red brick building erected by the emperor Nicholas for collections of armor and curious relics. A new and less costly palace was built by Alexander I., and is inhabited in summer by the imperial family. Conspicuous among the many churches is that connected with the palace, with gilded dome and cupolas. On the way to the neighboring Pavlovsk is a triumphal arch which Alexander I. erected to his comrades in the Napoleonic wars. In the same vicinity are imperial villas at Gatchina, Tchesme, and Krasnoye Selo, all, like Tzarskoye Selo, connected by rail with St. Petersburg.

TZSCHIRNER, Heinrich Gottlieb, a German theologian, born at Mittweida, Saxony, Nov. 14, 1778, died Feb. 17, 1828. He studied theology at Leipsic, entered holy orders in 1801, and became professor of theology at Wittenberg in 1805, and at Leipsic in 1809, superintendent at Leipsic in 1815, and prebendary of Meissen in 1818. He was one of the most effective opponents of the Catholic reaction in Germany. His works include a continuation of the church history of Schrökh (2 vols., Leipsic, 1810); *Protestantismus und Katholicismus aus dem Standpunkte der Politik betrachtet* (1822; translated into English, French, and Dutch); *Das Reactionssystem* (1824); *Briefe eines Deutschen an die Herren Chateaubriand, De Lamennais,* &c. (edited by Krug, 1828); *Vorlesungen über die christliche Glaubenslehre* (edited by Hase, 1829); and *Der Fall des Heidenthums* (unfinished; edited by Niedner, 1829).

U

U, THE 21st letter and 5th vowel of the English alphabet. It is not found in the Semitic languages, which have no distinct letters for vowels proper, and was probably originally wanting in the Greek, in which its modern equivalent is *ου*; in the Hebrew its place is supplied by the letter *vav* and in the Armenian by *hiun*, both of which are pronounced sometimes as vowels and sometimes as consonants. In the Latin also it frequently had the force of a consonant, as in the words *uaco*, *uelox*, *silua*, now written *vaco*, *velox*, *silva*. It was in fact constantly confounded with V, and for some time a distinction was made between U vowel and U consonant, the latter name being applied to the character V; and till near the close of the 16th century they were used interchangeably in printing, V sometimes only as the capital and sometimes as the initial letter in all cases, and *u* as the small letter in all cases or only in the interior of words. In the Gothic alphabets the distinction was made much earlier than in the Latin. In the so-called long sound peculiar to the English *u*, as in *dupe*, there is an intimate junction of the sounds of *e* and *oo*, exactly represented by *ew* in *few;* it is expressed in Italian and Spanish by *iu*, as in *fiume* and *ciudad*, and in French by *iou*, as in *Sioux.* In *u* initial, as in *unite*, the *e* is replaced by its liquid equivalent *y*, the pronunciation becoming *yoonite.* In an unaccented syllable, the union of a preceding *d*, *s*, *z*, or *t* with the *y* element of *u* produces the sound of *j*, *sh*, *zh*, or *ch*, as in *verdure*, *tonsure*, *measure*, *azure*, *virtue.* This effect also appears under accentuation in *sure* and its derivatives and *sugar*, and vulgarly in *sumach.* The short sound of *u* in *sup* is peculiar to the English and Dutch, being nearly equivalent to short *o* in most other languages, and to *eu* in French and *ö* in German. The normal sound of *u* in Italian, German, and most other European languages is *oo*, long and short. The latter is heard in the English *bull*, *full*, *pulpit*, &c. The former (as in *boot*) is commonly said to be the sound of *u* after *r*, as in *rule;* but the great majority of educated speakers, at least in the United States, seem to make this nearly identical with the *u* in *dupe.* In French the letter has a sound of its own (that of *e* modified in the direction of *oo*), which cannot be represented in our tongue, and resembling the German *ü.* In some cases in English, and in many more in other languages, *u* when followed by another vowel has the sound of English *w*, as after *q.* In English and French it is silent between *g* and a vowel, while in Spanish it is pronounced before *a;* in the latter again (as usually also in French) it is silent after *q*, for which *c* is substituted when the *u* is to be pronounced, as in *cuestion.* In Italian and German *u* is never silent.—U is interchangeable with *a*, as in the Arabic definite article, which is rendered *ul* and *al*, or in Ger. *Hut*, Eng. *hat;* with *i*, as Lat. *maxumus* and *maximus;* with *o*, as Lat. *dulcis*, It. *dolce;* with the diphthongs *æ* and *oi*, as Lat. *cura*, old form *coira* or *cœra;* with *au*, as Lat. *mus*, Ger. *Maus;* with *e*, as Lat. *Siculus*, Gr. Σικελός, Lat. *tabula*, Ger. *Tafel*, Ger. *Ulme*, Eng. *elm;* with *l*, as Eng. *stout*, Ger. *stolz*, Fr. *autel*, Eng. *altar.* U never occurs in ancient Latin inscriptions, V being used instead.

UBICINI, Jean Henri Abdolonyme, a French author, born in Issoudun, Oct. 20, 1818. He early explored the East, and in 1848 participated in the revolution at Bucharest, and became secretary of the provisional government. Subsequently he settled in Paris. His works include *Lettres sur la Turquie* (2 vols., 1849–'51; English, London, 1856); *La Turquie actuelle* (1855); and *La question des principautés danubiennes devant l'Europe* (1858). He has also translated the *Saturnalia* of Macrobius (1845) and edited the works of Voiture (1856), and for several years the *Revue de l'Orient.*

UCAYALI. See AMAZON, and PERU.

UCCELLO (PAOLO DI DONO), an Italian painter, born in Florence about 1390, died about 1472. He was called Uccello from his predilection for birds. He was the first painter to develop the principles of perspective. He painted principally in fresco. Few of his works remain.

UCHEES, a small tribe of American Indians, first found on both sides of the Savannah river as far down as the Ogeechee. They were civil, orderly, and industrious, and their women were noted for chastity. In the troubles about the time of the Yemassee war they moved to the Chattahoochee, and finally were merged in the Creek confederacy, emigrating with them to the Indian territory. Though long identified with the Creeks, they retain their own language and customs. The former is peculiarly harsh and guttural.

UDALL, Nicholas, an English author, born in Hampshire in 1506, died in 1564. He was educated at Oxford, was master successively of Eton and Westminster schools, and in the early part of the reign of Edward VI. was appointed to a canonry at Windsor. He published "Flovres for Latyne Spekynge" (London, 1533), a series of selections from Terence; some translations from the Latin works of Erasmus; and a Latin tragedy, *De Papatu* (1540). He was probably the first writer of regular English comedies, divided into acts and scenes. Wood says he wrote several, but only one is extant, "Ralph Roister Doister" (reprinted by the Shakespeare society, London, 1847).

UDINE. I. A N. E. province of Italy, in Venetia, embracing the larger portion of the former duchy of Friuli, and bordering on Austria and the Adriatic; area, 2,515 sq. m.; pop. in 1872, 481,586. The chief river is the Tagliamento. The N. part is covered with offshoots of the Alps, and the S. part is marshy; about one half of it is level. Agriculture has made considerable progress during the last 50 years, and the cereals produced in the level districts now suffice for the whole province. In the production of silk Udine occupies the first rank in Italy. It has also marble caves and sulphur springs. The province is divided into 17 districts. **II.** A town, capital of the province, in an extensive plain on the canal of La Roja, 60 m. N. E. of Venice, and 38 m. N. W. of Trieste; pop. about 26,700. It is walled and fortified, and has a fine cathedral, several hospitals, and a monumental pillar by Camalli, erected to commemorate the peace of 1797 concluded at the neighboring village of Campo Formio. The *campo santo* is one of the finest cemeteries in Europe.

UEBERWEG, Friedrich, a German historian of philosophy, born near Solingen, Rhenish Prussia, Jan. 22, 1826, died in Königsberg, June 7, 1871. He completed his studies at Göttingen and Berlin, and was a tutor at the university of Bonn from 1852 to 1862, and subsequently professor of philosophy at Königsberg. His works include *System der Logik und Geschichte der logischen Lehren* (Bonn, 1857; 3d ed., 1868; English translation by Thomas Lindsay, London, 1871), in which he agreed with Trendelenburg in the renewed founding of logic on Aristotelian principles; *Grundriss der Geschichte der Philosophie von Thales bis auf die Gegenwart* (3 vols., Berlin, 1862–'6; English translation from the 4th German ed., "History of Philosophy," by George S. Morris, with additions by President Porter of Yale college, a preface by Professors Henry B. Smith and Philip Schaff, and an appendix on Italian philosophy by Vincenzo Botta, New York, 1872–'4); and a translation of Berkeley's "Principles of Human Knowledge" (in Kirchmann's *Philosophische Bibliothek*, 1869), which gave rise to a controversy.—See *Friedrich Ueberweg*, by Prof. Fr. A. Lange of Zürich (Berlin, 1871).

UFA. I. An E. government of European Russia, bordering on Perm, Orenburg (of which till 1865 it formed the N. W. part), Samara, Kazan, and Viatka; area, 47,031 sq. m.; pop. in 1870, 1,364,925. The Ural mountains constitute the E. frontier; the rest of the surface is hilly or level. It is watered by the Bielaya river, a tributary of the Kama, and its numerous affluents, the most important of which is the Ufa. The region of the Bielaya is the most fertile in the Ural mountains. **II.** A city, capital of the government, at the confluence of the Ufa and Bielaya, built on rocks and surrounded by mountains, 200 m. N. by E. of Orenburg; pop. in 1867, 20,166. It is the seat of a Greek bishop and of a Mohammedan mufti, and has an ecclesiastical seminary, a gymnasium, 12 Greek churches, and a mosque. In January a large fair is held, lasting ten days. Ufa was laid out as a fortress toward the close of the 16th century, and was improved after a conflagration in 1816.

UGGIONE, Marco da. See OGGIONE.

UGOCSA, a N. E. county of Hungary, in the Trans-Tibiscan circle, bordering on the counties of Bereg, Mármaros, and Szatmár; area, 460 sq. m.; pop. in 1870, 67,498, chiefly Ruthenians and Magyars. The N. and E. parts are mountainous. It is intersected by the Theiss. Pastures, forests, and mines abound, and the principal pursuits are cattle raising and fishing. Capital, Nagy-Szöllös.

UGOLINO. See GHERARDESCA.

UGRIANS. See FINNS.

UHLAND, Johann Ludwig, a German poet, born in Tübingen, April 26, 1787, died there, Nov. 13, 1862. He graduated in law at Tübingen in 1810, and from 1812 to 1814 practised at Stuttgart in connection with the ministry of justice. He wrote poetry for periodicals as early as 1806. The war of independence against Napoleon roused his patriotic feelings, and the first collection of his *Gedichte* (1815) was received with great enthusiasm; and over 50 editions, gradually enlarged, have since appeared. In 1819 he became a member of the Würtemberg assembly. He was professor of the German language and literature at Tübingen from 1830 to 1833, when he resigned to take a more active part as a liberal leader in the diet, from which he retired in 1839. In 1848 he was a member of the Frankfort parliament. His works include, besides the above mentioned collection of *Gedichte*, the dramas *Ernst von Schwaben* and *Ludwig der Bayer* (1817–'19; 3d ed., 1863); *Alte hoch- und niederdeutsche Volkslieder* (1844–'5); and *Schriften zur Geschichte der Dichtung und Sage* (8 vols., 1865–'73), comprising his learned works relating to early German and Norse literature and mythology. He had in his days no superior as a lyrical poet. Longfellow has translated some of his pieces. Alexander Platt translated his "Poems" (Leipsic, 1848), W. W. Skeat his "Songs and Ballads" (London, 1864), and W. C. Sanders his "Poems" (1869).—See *Ludwig Uhland, seine Freunde und Zeitgenossen*, by Mayer (2 vols., Stuttgart, 1867); *Uhland's Leben*, edited by his widow (Stuttgart, 1874); and *Uhland und Rückert*, by S. Pfizer (1875).

UIGURS. See TURKS.

UINTAH, the W. county of Wyoming, bounded N. by Montana, S. by Utah, and W. by Utah, Idaho, and Montana; area, about 13,500 sq. m.; pop. in 1870, 856. It is crossed by the Rocky mountains, and contains the sources of the Green, Snake, Yellowstone, and Missouri rivers. It contains deposits of coal. The N. portion is occupied by the Yellowstone national park. (See WYOMING.) The Union Pacific railroad crosses the S. part. The Uintah mountains lie along its S. border in Utah, projecting E. from the Wahsatch range. Capital, Evanston.

UJIJI, a district of central Africa, on the E. shore of Lake Tanganyika, about half way between its centre and N. extremity, bounded N. by the district of Urundi, E. by Ubuha, S. by Ukaranga, and W. by the lake. The surface is hilly, the soil exceedingly fertile, and the climate humid. It is one of the most productive districts in the region. The principal crops are ground nuts, peas, beans, haricots, and holcus; but sugar cane, tobacco, and cotton are sometimes raised. Among the fruits are the Guinea palm and the plantain, and among the vegetables are the sweet potato, yam, egg plant, manioc, and cucumber. The inhabitants, the Wajiji, are a large, strong race, with dark skins, which they tattoo, woolly hair, and large flat feet and hands. What is generally called the town of Ujiji, or Kawele, is a collection of huts and mud hovels on the shore of the lake (lat. 4° 58′ 3″ S., lon. 30° 4′ 30″ E.), around a raised plot of ground called the bazaar, where the coast Arabs come to trade. It was here that Stanley found Livingstone, Nov. 10, 1871.

UKRAINE (Pol. *Ukraina*, border land), formerly the name of a S. E. province of independent Poland, on both sides of the Dnieper, and bordering on the Tartar territories. In later times it was divided into Polish and Russian Ukraine. Since 1793 it has wholly belonged to Russia, and it is now identical with Little Russia, comprising the governments of Kiev, Tchernigov, Poltava, and Kharkov. (See Cossacks.)

ULEABORG. **I.** The northernmost län of Finland, Russia, bordering on Norway and Sweden; area, 63,955 sq. m.; pop. in 1872, 185,890. It is mountainous, and contains a vast number of lakes and marshes, including Lake Enare. On account of its high latitude, it is little fitted for agriculture. The chief product is berries. The main pursuits are fishing and bird catching. **II.** A town, capital of the län, on a peninsula at the mouth of the Ulea (Swed. *Uleå*) in the gulf of Bothnia, 330 m. N. of Helsingfors; pop. in 1867, 7,602. It has a lighthouse, a fine church, and much industry and trade, in which it ranks next to Abo. On an adjacent island is the old castle of Uleaborg. In 1854 an English fleet destroyed much national Russian property at Uleaborg, as well as at Brahestad, in the same province.

ULEMA (the Arabic plural of *alim*, a learned man), the collective name of the body of learned men in Turkey. In a general sense ulema are persons who are learned in both law and divinity. They form a distinct body in Constantinople, whose office is to watch over the correct interpretation of the Koran and the right application of its teachings to law and polity. The head of the ulema is the grand mufti or *sheikh ul-islam;* next to him come the kaziaskiers, of whom there is one for Europe and one for Asia; the third class are the mollahs, the superior judges in the provinces; and after them are the cadis and the common muftis. (See Cadi, and Mufti.) The kaziaskiers have a voice and vote in the divan, and all cadis are appointed by and subject to them.

ULEX, a genus of much branched, very thorny shrubs of the *leguminosæ*, popularly called furze and gorse, and sometimes whin. The simple leaves are mostly reduced to mere prickles, and the numerous short branches terminate in spines; the axillary, yellow flowers have a calyx deeply divided into two lips, and colored like the petals; the stamens are united to form a complete tube; the pod is few-seeded. There are about a dozen species, natives of Europe and northern Africa; two are found in Great Britain, and others are sometimes cultivated. The common furze (*U. Europæus*) is a very social plant, often covering large tracts, forming a feature in the landscape, and when in flower is very attractive. In exposed situations it is a straggling bush, but in the shelter of woods it grows 10 ft. high, and in southern Europe 18 ft.; it is sometimes seen in collections of shrubbery in this country, but it is difficult to keep in the northern states; in England, though a native, in severe winters it is killed to the ground. The principal use of the plant is as a food for cattle; it has long been the custom in Normandy to cut the tops, and, after passing them through a mill to crush the spines, to feed them in the green state; it is there cultivated for this purpose, as it has been in parts of England, but its intrinsic value as food does not warrant the cost of its cultivation and preparation; its growth is encouraged in England as a game cover. There is a double-flowered variety, and another form with compact and erect branches called Irish furze. Some regard the dwarf or French furze as a variety of the preceding, while others consider it distinct (*U. nanus*); it is much smaller, and has deeper yellow flowers, which appear from August to December, while the other blooms in spring.

Furze or Gorse (Ulex Europæus).

ULFILAS, Ulphilas, Ulfila, or **Wulfila,** a Gothic bishop, born among the Goths in 310 or 311, died in Constantinople about 381. He is believed to have belonged to a family of Cappadocian Christians, whom the Goths had carried into captivity about 267. He was master of the Gothic, Greek, and Hebrew languages, became bishop of the Goths in 341, and in 348, at the head of the Christian minority of his people, and with the permission of the emperor Constantius, he settled in Mœsian territory, near Nicopolis. He persuaded his followers to devote themselves to agriculture and the peaceful arts, while the pagan majority only thought of war. He propagated among his people the love of letters, formed an alphabet of 24 characters based on the Greek, and translated for popular use into Mœso-Gothic the whole Bible except the books of Kings. This version, in which it is thought he was assisted by his friend and successor Senelas, and of which only fragments exist, is the earliest known specimen of the Teutonic language. Among its recent editors and commentators are Gabelenz, Löbe, Massmann, and Stamm. A new edition, by E. Bernhardt, with various readings, a commentary, and critical introduction, together with the Greek text, appeared at Halle in 1876. Ulfilas's Bible was in constant use among the Gothic peoples so long as they preserved their nationality. (See GOTHIC LANGUAGE AND LITERATURE, vol. viii., pp. 124, 125, and ARGENTEUS CODEX.) He was a semi-Arian, subscribed the creed of Rimini in 359, was at the Arian synod of Constantinople in 360, and died while attending the œcumenical council of 381.—See Waitz, *Ueber das Leben und die Lehre des Ulfilas* (1840), and Bessel, *Ueber das Leben des Ulfilas und die Bekehrung der Gothen* (1860).

ULLMANN, Karl, a German theologian, born at Epfenbach, Bavaria, March 15, 1796, died in Carlsruhe, Jan. 12, 1865. He was successively professor at Halle and Heidelberg, and in 1853 became bishop of the state church in Baden, and in 1856 president of the supreme ecclesiastical council, retiring in 1860. He was a friend and adopted the views of Schleiermacher. In 1828 he joined Umbreit in establishing the Protestant quarterly review entitled *Studien und Kritiken*, for which he wrote able essays, afterward enlarged in separate publications. His works include *Gregor von Nazianz* (Darmstadt, 1825); *Historisch oder mythisch?* directed against Strauss's "Life of Christ" (Hamburg, 1838); *Ueber den Cultus des Genius* (1840; English translation, "The Worship of Genius," London, 1846); *Ueber die Reformatoren vor der Reformation* (2 vols., 1841; English translation, "Reformers before the Reformation," by Robert Menzies, 2 vols., Edinburgh, 1855); *Ueber die Sündlosigkeit Christi* (1841; 7th ed., Gotha, 1863; English translation, "Apologetic View of the Sinless Character of Jesus," Edinburgh, 1841); and *Ueber das Wesen des Christenthums* (Hamburg, 1845; 4th ed., Gotha, 1854).

ULLOA, Antonio de, a Spanish naval officer, born in Seville, Jan. 12, 1716, died in the Isla de Leon, near Cadiz, July 3, 1795. He was educated for the navy, became in 1733 a member of the royal marine guards, and in 1735 a lieutenant, when he was sent to South America with the French academicians who were commissioned to measure a degree of the meridian at the equator. From this he was called away to assist in putting the coast in a state of defence against Lord Anson's expedition. In October, 1744, he embarked for Europe, but was captured by the British, and carried to London, where his scientific friends obtained his liberty, and made him a member of the royal society. On his return to Spain in 1746 he wrote a history of the expedition, the scientific portion being written by his companion, Jorge Juan (4 vols., Madrid, 1748; translated into English, "A Voyage to South America," 2 vols., London, 1772; 4th ed., 1806). In 1755 he went a second time to America, and after the peace of 1763 was made governor of Louisiana, where he arrived in March, 1766. An insurrection obliged him to leave the colony, and he returned to Europe. In 1772 he published a volume of essays on the natural history and antiquities of America, and in 1778 "Observations of a Solar Eclipse made at Sea." He was now a lieutenant general in the naval service, and was appointed to the command of a squadron intended to capture off the Azores an English merchant fleet heavily laden, and afterward to sail to Havana and join an expedition fitting out against Florida. Absorbed in his scientific investigations, Ulloa forgot to open his sealed orders, and after cruising about for two months without success returned. He was tried in 1780 by a court martial demanded by himself, and, though acquitted, never again engaged in active service.

ULM, a city of Würtemberg, capital of the circle of the Danube, situated in a fertile valley on the left bank of the Danube at its junction with the Iller and Blau, and at the foot of the E. spurs of the Swabian Alps, 45 m. S. E. of Stuttgart; pop. in 1871, 26,214. The Danube becomes here fully navigable, and forms the boundary between Würtemberg and Bavaria. The town has the quaint and stately aspect of most former imperial cities, and contains many memorable public and private buildings. The *Münster* is one of the most celebrated achievements of early German architecture, and one of the largest Protestant churches in Germany. Its stained glass windows are of remarkable finish, and it has many works of art and a very large organ. The tower, originally designed to be 500 ft. high, only rises to about 250 ft. The edifice has been for some time in process of restoration. The provincial authorities occupy the former palace of the order of Teutonic knights, and there is also a royal palace. The city library, one of the earliest in Germany, contains a collection of remarkable antiquities. Ulm is one of the great commercial centres of Würtemberg, though railway traffic has become a formidable rival of the trade on the Danube. The railways to Stuttgart, Friedrichshafen, Augsburg, Kempten, and Blaubeuern all form a junction at Ulm in a single station. The products include fine flour and pipe bowls, which have a wide reputation. The trade is especially active in deals. —Ulm was formerly an imperial city of the Swabian circle, and held the most prominent place in the Swabian diet. In the 15th century it had more than 50,000 inhabitants, besides 40,000 in the adjoining territory, then belonging to the town. Its wealth became proverbial, but the strategical importance of Ulm involved it in nearly all great German wars. In 1803 it was annexed to Bavaria. The Austrian general Mack surrendered here to Napoleon, Oct. 20, 1805, with his entire army of 23,000 men. Subsequently it was restored to Bavaria, and in 1810 it was allotted to Würtemberg, the former country retaining only the village of Neu-Ulm, on the opposite bank of the Danube. The extensive fortifications of Ulm are situated partly in Würtemberg, partly in Bavarian territory.

ULPIAN (Domitius Ulpianus), a Roman jurist, assassinated at Rome, A. D. 228. He was of Tyrian origin, and during the reigns of Septimius Severus and Caracalla wrote juristical works. When Elagabalus ascended the throne in 218 he was banished, but in 222 he became one of the chief advisers of Alexander Severus, who made him *Scriniorum magister*, *consiliarius*, and *præfectus annonæ*. He also held the office of prætorian prefect. He was killed by the soldiers in the presence of the emperor and his mother. Ulpian was one of the most distinguished of the Roman jurists, and from his works were taken about one third of the excerpts made for Justinian's Digest.

ULRICI, Hermann, a German philosopher, born at Pförten, Lusatia, March 23, 1806. He was educated at Halle and Berlin, and practised law for some time, but in 1829 devoted himself to philosophical studies, and in 1834 became professor at Halle. He was also one of the joint editors of the *Zeitschrift für Philosophie.* His position in philosophy is independent, and he strives to mediate between realism and idealism. His works include *Geschichte der hellenischen Dichtkunst* (2 vols., Berlin, 1835); *Ueber Shakspeare's dramatische Kunst* (Halle, 1839; 3d ed., 1868; English translation by A. I. W. Morrison, London, 1846); *Ueber Princip und Methode der Hegel'schen Philosophie* (1841); *Das Grundprincip der Philosophie* (Leipsic, 1845–'6); *System der Logik* (1852); *Glauben und Wissen, speculative und exacte Wissenschaft* (1858); *Compendium der Logik* (1860; enlarged ed., 1872); *Gott und die Natur* (1862; 2d ed., 1866); *Gott und der Mensch* (1866 *et seq.*); *Zur logischen Frage* (Halle, 1870); and *Der Philosoph Strauss* (1873).

ULSTER, a S. E. county of New York, bounded E. by the Hudson river, and drained by the Esopus, Rondout, and Wallkill creeks; area, 1,204 sq. m.; pop. in 1875, 88,271. The surface is broken by the Catskill and Shawangunk ridges, and the soil is generally best adapted to grazing. Iron ore, limestone, slate, and marl are found, and there are indications of the existence of coal, lead, plumbago, and alum. Large quantities of flagging stone are exported. The Delaware and Hudson canal passes through it, and it is also intersected by the New York, Kingston, and Syracuse railroad. The chief productions in 1870 were 42,532 bushels of wheat, 107,502 of rye, 394,004 of Indian corn, 447,837 of oats, 132,515 of buckwheat, 688,435 of potatoes, 1,631,956 lbs. of butter, 41,595 of wool, and 97,995 tons of hay. There were 8,928 horses, 17,640 milch cows, 12,597 other cattle, 14,119 sheep, and 14,070 swine. There were 690 manufacturing establishments; capital invested, $4,938,201; value of products, $10,213,187. The principal manufactories were 54 of carriages and wagons, 3 of hubs and wagon material, 10 of bricks, 11 of cement, 13 of cooperage, 2 of edge tools and axes, 14 of furniture, 1 of glass ware, 9 of iron, 3 of lime, 4 of machinery, 7 of marble and stone work, 1 of paints, 4 of paper, 5 of woollens, 38 saw mills, 6 breweries, 15 tanneries, and 34 flour mills. Capital, Kingston.

ULSTER, one of the four provinces of Ireland, constituting the N. part of the island, bounded W. and N. by the Atlantic ocean, E. by the North channel and Irish sea, S. E. by Leinster, and S. W. by Connaught; area, about 8,550 sq. m.; pop. in 1871, 1,830,398, nearly half of them Protestants. It is divided into the counties of Antrim, Armagh, Cavan, Donegal, Down, Fermanagh, Londonderry, Monaghan, and Tyrone. The coasts are generally rugged and indented by numerous bays and harbors, the chief of which are Carlingford bay, Dundrum bay, Strangford lough, Belfast lough, Lough Larne, Lough Foyle, Lough Swilly, Mulroy bay, Sheep Haven, and Donegal bay. The principal rivers are the Erne, Foyle, Bann, and Lagan. A considerable part of the surface is mountainous, and two chains traverse the province from E. to W., the highest peaks being in the counties of Donegal and Down; Errigal in the former and Slieve Donard in the latter are respectively 2,460 and 2,796 ft. high. Between these ranges is an extensive tract of undulating ground, near the centre of which is Lough Neagh. Other large lakes are Upper and Lower Lough Erne, and Loughs Melvin, Sheelin, Oughter, Derg, Esk, and Veagh. Ulster is the seat of the Irish linen manufacture, which supports about one fourth of the population. Cotton is extensively manufactured in Belfast and vicinity. Internal communication is facilitated by railways and canals, and numerous excellent roads.—Ulster was partly conquered and held as an earldom under Henry II. by John de Courcy, from whom it was transferred to Hugh de Lacy; and by descent from him, through the De Burgh and Mortimer families, the title was merged in the crown of England under Edward IV. James I. colonized Ulster with Scotch and English Protestant settlers, to whom he gave grants of land in lots of 1,000, 1,500, and 2,000 acres. The insurrection of 1641 was to overthrow these Protestant settlements. Several towns were taken, the country was devastated, many thousand lives were sacrificed, and it was not till 1649 that the rebellion was completely quelled.

ULTRAMARINE, a beautiful blue pigment originally made from lapis lazuli (see Lapis Lazuli), but now prepared in large quantities artificially. Its fabrication was suggested by the discovery of blue masses on taking down soda furnaces and lime kilns; and the *société d'encouragement* at Paris in 1824 offered a prize of 6,000 francs for its production, which was awarded to Guimet of Toulouse in 1828. A mode of preparation had previously been published by Christian Gmelin, in the beginning of the same year. Guimet's process was first applied on the manufacturing scale, but was kept secret. Gmelin's process was long followed, but many others have finally come into use. The following process, given by Prof. Miller of London, answers well upon a small scale: An intimate mixture of 100 parts of finely washed kaolin, 100 of sodic carbonate, 60 of sulphur, and 12 of charcoal is exposed in a covered crucible to a bright red heat for three hours and a half. The residue, which should not be in a fused condition, is green. The product after grinding is well washed, dried, and mixed with one fifth of its weight of sulphur, and exposed in a thin layer to a gentle heat a little above that required to burn off the sulphur, which being accomplished the process is repeated two or three times, until the mass becomes bright blue. The green modification, the product of the initial process, is also manufactured for the market. There is some doubt as to the nature of the coloring matter of ultramarine. According to the experiments of Wilkens, ultramarine is composed of two portions, one constant, containing the coloring matter and soluble in hydrochloric acid, while the other contains a variable amount of clay, ferric oxide, and sulphuric acid.

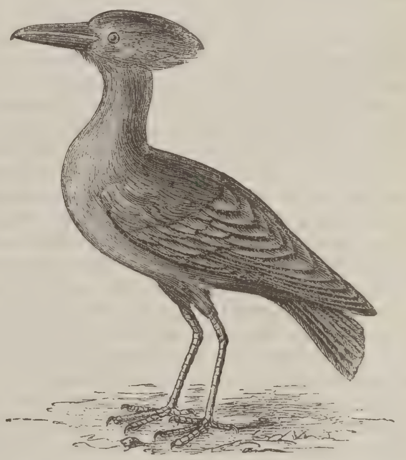
ULTRAMONTANISTS (Lat. *ultra montes*, beyond the mountains), the name formerly applied to all theologians in the Roman Catholic church who advocated the highest spiritual and temporal power of the papacy, and bestowed since 1870 on all who accept the decrees of the Vatican council. The name originated with the French Gallicans, who denied to the popes all right to depose sovereigns or to interfere in the temporal affairs of states and of national churches, and maintained that the doctrinal judgments of the popes only become infallible and binding on the conscience when confirmed by the consent of the church, and that the authority of a general council is superior to that of the pope. The contrary view being held "beyond the Alps" and throughout Italy, its supporters were called *Transalpini* and *ultramontani*. At the council of Constance, where these adverse opinions came conspicuously into conflict, the designation of ultramontane was extended to persons of every nationality who denied the superiority of the council over the pope. After that council the question of the direct or indirect power of the papacy over states and sovereigns became the chief point of dispute, and the question everywhere assumed a national character. In Germany Febronius (Bishop Hontheim) wrote a powerful work against ultramontanism; and in 1786, at the convention of Ems, the archbishops of Mentz, Treves, Cologne, and Salzburg denounced it. In Italy its chief opponent in the last century was Scipione Ricci, bishop of Pistoja, who convened a synod in that city in September, 1786, and promulgated disciplinary decrees and a doctrinal exposition favoring extreme Gallicanism and Jansenism. These were partly confirmed, April 23, 1787, by an assembly of the bishops of Tuscany; but the grand duke, who had been the chief promoter of these measures, having become emperor as Leopold II. in 1790, allowed his successor to restrain and punish Ricci and his followers. The acts of the synod of Pistoja were condemned by Pius VI. in the dogmatic bull *Auctorem fidei* of Aug. 28, 1794. The political aspects of ultramontanism were once more brought into prominent notice in 1869-'70 in connection with the council of the Vatican and the doctrine of papal infallibility. Since then the tendencies of ultramontanism in its bearings on civil allegiance have been vehemently discussed, especially in Germany, Switzerland, Italy, and England.

ULYSSES, or **Odysseus** (Gr. 'Οδυσσεύς), one of the Greek leaders at the siege of Troy. According to the Homeric account, he was the son of Laërtes and Anticlea, and married Penelope, the daughter of Icarius, by whom he had a son named Telemachus. He ruled in Ithaca, and only with great difficulty could be induced to join the expedition against Troy. According to one form of the legend, he simulated insanity to avoid taking part, and ploughed the sand on the beach; Palamedes exposed the deception by placing his infant son Telemachus in the furrow, at which Ulysses turned the plough aside. The falsity of his madness being thus disclosed, he joined the Grecian fleet at Aulis with 12 ships, and when the expedition had reached Tenedos was sent with Menelaus to Troy to demand Helen and the stolen property. The mission was unsuccessful. In the ten years' war he was distinguished for his prowess as a warrior, but far more for his eloquence, sagacity, and inexhaustible resources under difficulties. After the death of Achilles his armor was offered as a prize to the greatest warrior in the Greek army, and Ulysses and Ajax became rivals for the honor, the former proving successful. By his contrivance the Palladium was carried away from Troy by stealth, and he was one of the heroes concealed in the wooden horse which the Trojans to their ruin introduced into the city. His ten years' wanderings after the close of the siege form the subject of the Odyssey. After various adventures he was thrown upon the coasts of the Lotophagi, where his companions, having eaten of the lotus, wished to remain. But he induced them to depart, sailed to the island of the Cyclops, and with 12 of his followers entered the cave of Polyphemus, who devoured six of his companions. Ulysses made the giant drunk with wine, put out his one eye with a burning pole, and then tying himself and his companions under the bodies of the sheep, escaped when these were let out of the cave. Polyphemus implored his father Neptune to visit Ulysses with his vengeance, and the remainder of his voyage was constantly disturbed. Reaching the island of Æolus, Ulysses was presented by that deity on his departure with a bag containing the winds that were to bring him home; but his followers opened the bag without his knowledge, the winds escaped, and the vessels were driven back to the island. After six days he reached the country of the cannibal Læstrygones, from which he escaped with only one ship. Thence he sailed to Ææa, inhabited by the sorceress Circe, who changed part of his followers into swine. Through the aid of Mercury he overcame her spells, and his companions resumed their human shape. Circe now treated them kindly, and by her advice Ulysses descended into Hades to consult the seer Tiresias. The prophet assured him that everything would turn out right if the herds of Helios in Trinacria should be left unharmed. Returning to Ææa, he was carried to the island of the sirens, but by filling the ears of his companions with wax and tying himself to the mast he passed them in safety. His ship then came between Scylla and Charybdis, and the monster Scylla carried off and devoured six of his companions. Coming to Trinacria, he was compelled by his companions to land. There they were detained by storms, and while he was sleeping some of the finest of the cattle of Helios, which they had sworn not to touch, were killed and eaten by his followers. As soon as they were again on the open sea, another storm arose, and the vessel was destroyed by lightning, all on board being drowned except Ulysses. He was carried to the island of Ogygia, inhabited by the nymph Calypso, who promised him immortality and eternal youth if he would marry and remain with her. But after a stay of seven years he embarked on a raft, and reached Scheria, from which place he was sent to Ithaca in a ship, having been absent 20 years. He found his wife beset by suitors (see PENELOPE), all of whom he slew with the aid of Minerva and his son Telemachus. Of his later life and of his death there are different accounts. In one, his son Telegonus by Circe, being sent to look for his father, and being shipwrecked on Ithaca and beginning to plunder for the sake of obtaining food, was attacked by Ulysses and Telemachus, and in the contest that followed Telegonus slew his own father.

UMATILLA, a N. E. county of Oregon, bordering on Washington territory, bounded N. W. by the Columbia river and E. by the Blue mountains, and watered by the Umatilla river and other streams; area, 5,300 sq. m.; pop. in 1870, 2,916, of whom 70 were Chinese. The river valleys are fertile; back of these are rolling prairies and high table lands covered with pasturage, and beyond these hills well wooded with pines. Gold is mined in the mountains and on the bars of the Columbia. Coal, copper, and iron are also found. The chief productions in 1870 were 28,209 bushels of wheat, 9,789 of Indian corn, 56,634 of oats, 11,782 of barley, 26,413 of potatoes, 97,564 lbs. of wool, 72,730 of butter, and 3,394 tons of hay. There were 13,712 horses, 7,317 milch cows, 9,240 other cattle, 29,960 sheep, and 2,027 swine. Capital, Pendleton.

UMBER, a pigment much used by artists for brown and grave colors. It is made from an argillaceous brown hematite having the formula $2Fe_2O_3,3H_2O$, by roasting, pulverizing, and mixing it with variable proportions of clay or ochre, and sometimes with a little oxide of manganese, or it may be used alone. Ordinary roasting does not drive off all the water, and in this state it is called raw umber. When strongly heated it is completely dehydrated, and is called burnt umber. It is used both in oil and water colors, and is often mixed with other pigments.

UMBRE, a wading bird of the heron family, and genus *scopus* (Briss.). The bill is longer than the head, elevated at the base, compressed laterally, keeled above and below, and a little bent at the point; the nostrils prolonged in a furrow; third and fourth quills equal and longest; tail short and even; tarsi longer than middle toe and scaled; front toes united by membrane to first phalanx, the hind one resting wholly on the ground; claws short and slightly curved. The only described species, the tufted umbre (*S. umbretta*, Gmel.), is 20 in. long, with a bill of 3½ in.; the color is a uniform umber brown, the wings and tail barred with darker; the male has an occipital crest about 4 in. long, of loose feathers. It is a native of Africa.

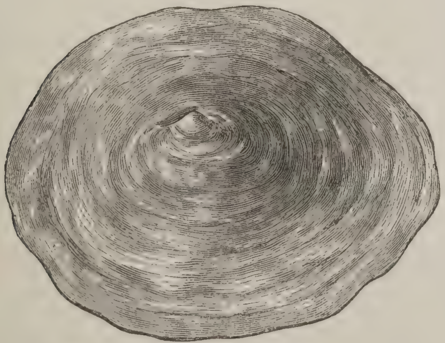


Tufted Umbre (Scopus umbretta).

UMBREIT, Friedrich Wilhelm Karl, a German Protestant theologian, born at Sonneborn, Gotha, April 11, 1795, died in Heidelberg, April 26, 1860. He studied theology at Göttingen, especially under Eichhorn, and wrote a prize essay, *Commentatio Historiam Emirorum-al-Omrah ex Abulfeda exhibens* (Göttingen, 1816). In 1820 he was appointed extraordinary professor of theology and philosophy in Heidelberg, in 1823 ordinary professor of philosophy, and in 1829 ordinary professor of theology. His works include *Lied der Liebe* (Göttingen, 1820); *Uebersetzung und Auslegung des Buches Hiob* (Heidelberg, 1824); *Commentar über die Sprüche Salomos* (Heidelberg, 1826); *Christliche Erbauung aus dem Psalter* (Hamburg, 1835); *Grundtöne des Alten Testaments* (Heidelberg, 1843); and *Commentar über die Propheten des Alten Testaments* (4 vols., Hamburg, 1841–'6), his principal work. He was also, with his friend Dr. Ullmann, editor of the *Studien und Kritiken*, the principal theological quarterly of Protestant Germany.

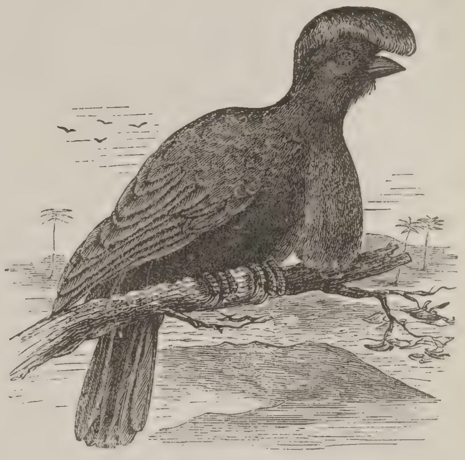
UMBRELLA (diminutive of Lat. *umbra*, a shade), a folding shade or screen, carried over the head as a protection from rain or sun. When small and used by ladies only as a sunshade, it is called a parasol (Ital. *parare*, to ward off, and *sole*, the sun). An umbrella consists of a frame covered with silk, cotton, alpaca, or other material, which can be expanded at pleasure or brought down snugly around a central stick. This stick is furnished at the lower end with a handle, and near the upper end is a metallic ring (the top notch), around which are hinged the upper ends of the ribs to which the cover is attached. Near the middle of each rib is hinged a metallic rod or stretcher, of which the lower ends all meet in a ring (the runner), sliding from the handle up far enough to spread out the ribs to the required extent. The number of ribs is usually 8, although 6, 7, 9, 10, 12, and 16 have been employed, and in the Chinese and Japanese umbrellas they amount to 40 or 50. Rattan is largely used for the ribs of the cheapest umbrellas, but its employment is steadily diminishing. Whalebone, which at one time was the principal material for the ribs, has been almost entirely superseded by steel, which, combining strength with lightness, has rapidly grown in favor since its introduction about 1840. Modern improvements have generally been in the reduction of the weight and the greater perfection of the mechanism. The most important step in this direction was the invention of the paragon ribs, patented in England in 1852 by Samuel Fox. These are of sheet steel rolled in a semi-elliptical shape, making the least weight of material with the greatest strength. The weight of the other metallic parts of the umbrella has also been much reduced within 30 years. The sticks for common umbrellas are generally made from planks sawed into strips, then turned, and bent or curved; maple is largely used for this purpose. The better class of sticks are root-ended, such as bamboo, partridge or hair wood, pimento, dogwood, myrtle, and orange. Metal tubes have been used quite largely at times. Handles are made of wood, ivory, bone, horn, tortoise shell, and a great variety of other materials. The covering of the umbrella of 50 years ago was oiled silk or glazed cotton cloth, which was very cumbrous and inconvenient; now silk, cotton, and alpaca or similar worsted fabrics are the principal materials. Cotton fabrics are sometimes, after dyeing, treated to render them less pervious to water, and to fasten the color. The Chinese and Japanese umbrellas are made entirely of bamboo, paper, and twine. Sliding caps to fit over the ends of the ribs, and hold the umbrella closed, have lately come into general use. Folding umbrellas are among the early inventions of which there are recorded patents, but they have never attained to general favor, being complicated and troublesome. Among other forms are umbrellas enclosed in walking sticks, self-opening, with sticks on which the cover can be thrown to one side, with windows in the covering, and with every variety of form and attachment. The English patent records show nearly 300 patents from 1780 to 1866 for improvements or changes in umbrellas. From 1808 to 1848, 124 patents were granted in France; and in 1873, 25 patents were taken out in the United States, bearing upon the same subject. Yet very few changes of any value are produced.—The umbrella is found sculptured on the ruins of Nineveh and on the monuments of Egypt. In China and India its use is very ancient. It had also apparently some religious signification. In the fifth incarnation of Vishnu, the god is spoken of as going down to the infernal regions bearing an umbrella in his hand. In the Scirophoria, the feast of Athena Sciras, a white parasol was borne by the priestesses from the Acropolis to the Phalerus; and the umbrella was also used in the feasts of Bacchus. The ancient Greeks and Romans had umbrellas, which from the paintings on vases appear to have been very much like those of the present time; they were used only by women. In many countries the umbrella seems to have been part of the insignia of royalty, and its use permitted only to the king and great nobles. This still continues in some parts of Asia and Africa, and in many cases it is made very large and much ornamented. The umbrellas of the Siamese kings are said to be made with several separate circles one above another, while the nobles use them with only a single circle. During the middle ages there are occasional references to umbrellas. In the basilican churches of Rome was suspended a large umbrella, and the cardinal who took his title from the church had the privilege of having an umbrella carried over his head in solemn processions. In Wright's "Domestic Manners of the English" (1862) a drawing is given from the Harleian MS. No. 603, representing an Anglo-Saxon gentleman walking out, attended by his servant carrying an umbrella with a handle that slopes backward, so as to bring the umbrella over the head of the person in front. Until a comparatively recent time umbrellas were used in Italy and France only as a protection from the sun. Kersey's "English Dictionary" (1708) defines an umbrella as a "screen commonly used by women to keep off rain." Jonas Hanway is said to have been the first man who commonly carried an umbrella in the streets of London, about 1750; at that time their use was considered a mark of great effeminacy. They were at first kept in the halls of great houses, and at coffee houses, to be used in passing from the door to the carriage. In 1787 an English advertisement speaks of "a great assortment of much approved pocket and portable umbrellas."—For a considerable time after the introduction of umbrellas into the United States, in the latter half of the 18th century, it was considered effeminate to carry one. Their manufacture was begun about 1800, and has risen to be an important branch of industry, the products equalling the best English and French. It is confined almost entirely to the cities of Philadelphia, New York, and Boston. By the census of 1870, the number of hands employed directly in the making of umbrellas and canes was 2,618, and the value of the production $4,098,032; and since that time the business has maintained a steady growth.—The silk for covering umbrellas is a special branch of weaving, principally carried on about Lyons, France; but the neighborhood of Crefeld on the Rhine also produces a large quantity, and in Switzerland and England a limited quantity is made. Some silks and alpacas for umbrellas have been made in the United States, but not with much success. The manufacture of the metal parts and of the handles is generally a separate branch. The census of 1870 gives 578 hands employed upon metallic umbrella furniture, producing a value of $724,034.

UMBRELLA (Lam.), a genus of gasteropod mollusks, so called from the resemblance of the flattened shell to an umbrella. The animal has a very large tuberculated foot, deeply notched in front; the shell is small and limpet-like, merely covering the most important organs. The *U. umbellata* (Lam.), the Chinese umbrella shell, is a native of the Indian ocean.



Umbrella umbellata.

UMBRELLA BIRD, the popular name of a singular South American bird, placed by the latest authors among the chatterers (*ampelidæ*), subfamily *gymnoderinæ* or fruit birds, and genus *cephalopterus* (Geoffr.). The bill is stout, long, flattened, gradually curved, with the tip notched and slightly hooked; wings moderate, rather pointed, with the third quill longest; tail short and rounded; toes long and slender, with curved claws. The *C. ornatus* (Geoffr.) is about as large as a crow, glossy black, with violet, blue, and metallic reflections on the crest and pectoral appendage. The head of the male is surmounted by a large crest of 50 to 80 feathers springing from over the nostrils, the lower half a white stiff shaft, and terminating each in a tuft of black hair-like feathers spreading in all directions, but principally forward; it arises from a contractile skin on the top of the head, and when erected almost hides the bill from view; it is 5 in. in length and about 4½ in. wide, somewhat resembling a beautiful blue umbrella. The skin of the neck is very loose, and from it grows a cylindrical fleshy process, about as thick as a goose quill, 1½ in. long, from which extends a tuft of imbricated feathers, bordered with metallic blue, and hanging down several inches. It is found in the islands of the great South American rivers, feeding principally on fruits; it is arboreal, and utters a very loud and deep note, which has gained for it from the tribes of the Rio Negro the name of piper bird.—The araponga or bell bird (*procnias alba*, Thunb.) is about 12 in. long and pure white; it has a singular cylindrical fleshy appendage, with a few small feathers, rising from the base of the bill; the mouth is very wide; the voice resembles the tolling of a bell, and may be heard, according to Wa-



Umbrella Bird (Cephalopterus ornatus).

terton, nearly three miles, and during the heat of the day, when most other birds are silent; it is a native of the forests of tropical South America.

UMBRIA, a country of ancient Italy, bounded N. by Cisalpine Gaul, E. and S. by the Adriatic, Picenum, and the territory of the Sabines, and W. by the Tiber, separating it from Etruria. Its principal cities were Ariminum (now Rimini), Pisaurum (Pesaro), Fanum Fortunæ (Fano), Sena Gallica (Sinigaglia), Narnia (Narni), Iguvium (Gubbio), Fulginium (Foligno), and Spoletium (Spoleto). The N. E. part stretched out toward the coast in fertile plains. Besides the Tiber, the principal rivers were the Rubicon, Ariminus (Marecchia), Pisaurus (Foglia), Metaurus (Metauro), and Æsis (Esino), all flowing into the Adriatic, and the Nar (Nera), an affluent of the Tiber. The inhabitants, the Umbri, were one of the most ancient races of the peninsula, and at an early period became the most powerful people of central Italy. Etruria was originally in their possession. The Romans overcame them in 308 B. C. The battle of Sentinum, 295 B. C., when the Samnites, Gauls, Etruscans, and Umbrians were defeated by the Romans under Quintus Fabius, is sometimes called the battle of Umbria.—The name Umbria has been revived in modern times to designate a portion of what was formerly the Papal States, comprised chiefly in the delegations of Spoleto and Perugia. It constitutes now a province of the kingdom of Italy, also called Perugia. (See PERUGIA.)

UMPQUA, a river of Oregon, which, rising in the Cascade mountains and pursuing a general W. N. W. course, breaks through the Coast range and flows into the Pacific ocean at Umpqua head, lat. 43° 41′ N. It has a total length of about 200 m., and is navigable by steamers of light draught to Roseburg, about 90 m. from its mouth, though more than half this distance is obstructed by rapids.

UNAU. See SLOTH.

UNCAS, a North American Indian, sachem of the Mohegan tribe in Connecticut, died about 1682, at a great age. He was originally a war chief of the Pequot nation, but about 1635 revolted from the Pequot sachem Sassacus, and gathered a band of Indians who were known by the old title of Mohegans once borne by the Pequots. In May, 1637, he joined the English in the war against the Pequots, and proved a valuable auxiliary, receiving for his services another portion of the Pequot lands. Many of the Pequots were shielded by him from the vengeance of the English when the war was over, and for this he was for a time in partial disgrace with the authorities; but he was soon received again into so great favor with the whites that several attempts were made by different Indians to assassinate him. Uncas accordingly attacked and reduced Sequasson, sachem of the Connecticut river, and in 1643 defeated and took the powerful Narragansett sachem Miantonomoh, whom he finally put to death. He was a brave but tyrannical chief, and frequent complaints were made to the colonial government of his oppression. In 1648 the Mohawks, Pocomtocks, and other tribes made war against Uncas with but little success. He was besieged in 1657 in his stronghold on the Connecticut by the Narragansett chief Pessacus, and nearly starved out; but he was relieved at almost the last moment by Ensign Leffingwell, who took in to him at night a canoe laden with supplies. For this act, it is said, Uncas gave to Leffingwell a deed for all the land upon which the town of Norwich now stands, though that chief afterward sold it to a company. He was characterized in 1674 as "an old and wicked, wilful man, a drunkard, and otherwise very vicious; who hath always been an opposer and underminer of praying to God." He was the ally of the English in all their wars against the Indians.

UNG, a N. E. county of Hungary, in the Cis-Tibiscan circle, bordering on Galicia and the counties of Zemplén, Szabolcs, and Bereg; area, 1,180 sq. m.; pop. in 1870, 130,032, the majority Slavs, and the rest Magyars. The N. part of the county is traversed by thickly wooded branches of the Carpathians, and it is watered by the Ung and the Latorcza. The chief products are rye, oats, wine, and hemp. It contains the mineral springs of Szobráncz. The capital, Ungvár, is situated on the Ung, 85 m. N. N. E. of Debreczin; pop. in 1870, 11,017. It is the seat of a United Greek bishop, and has an episcopal seminary and lyceum, a gymnasium, an ancient castle, and mineral springs.

UNGER, Franz, a German palæontologist, born in Styria in 1800, died in Gratz, Feb. 13, 1870. He took his medical degree in Vienna in 1827, and practised as a physician till 1836, when he became professor of botany at Gratz, whence he removed in 1850 to the university of Vienna. His most noteworthy publications are *Anatomie und Physiologie der Pflanzen* (1855); *Botanische Streifzüge auf dem Gebiete der Culturgeschichte* (1857 *et seq.*); *Geologie der europäischen Waldbäume* (1869 *et seq.*); and *Ueber Lieschkolben der Vorwelt* (1870). His life has been written by Reyer (Gratz, 1871).

UNGUICULATA, and **Ungulata,** terms originally applied by Ray to mammals, according as they possessed claws or hoofs, though Aristotle had made a similar division of quadrupeds, placing among unguiculates the monkeys, bats, carnivora, and rodents, and among the ungulates the pachyderms, ruminants, and solipeds (horse). Ray placed among unguiculates the camel, elephant, and edentates, as well as those above mentioned; Linnæus followed Ray in his division of quadrupeds. This system has been variously modified by Cuvier, Swainson, Oken, C. L. Bonaparte, and Owen, the last restricting the unguiculates to the monkeys and carnivora, and the ungulates to the omnivora, ruminants, solipeds, and pachyderms. The ungulates are divided by Huxley into the two sections of perissodactyls or odd-toed, and artiodactyls or even-toed; the former including the rhinoceros, tapir, and horse, the latter the omnivorous pig and hippopotamus, and the ruminating animals. (See MAMMALIA, vol. xi., pp. 79, 80, and 82.)

UNICOI, an E. county of Tennessee, separated from North Carolina by the Unaka mountains, and watered by the Nolichucky river and its tributaries; area, about 300 sq. m.; pop. about 2,000. It was formed in 1875 from Carter and Washington counties. It is a rugged mountain region, some peaks attaining a height of 5,500 ft. The arable land is confined to a few valleys and river basins. The slopes are well wooded with pine, chestnut, hemlock, cherry, spruce, and poplar. The tops of some of the peaks are bald, and furnish good pasturage. Iron ore is abundant. The climate is severe in winter, but cool and bracing in summer. Wheat, corn, oats, buckwheat, rye, and potatoes are the chief crops. Apples flourish, and peaches grow well in the recesses of the mountains. Capital, Longmire.

UNICORN, a fabulous animal resembling a horse, with a single horn issuing from the middle of the forehead, well known as the supporter with the lion of the coat of arms of England. The unicorn of various versions of the Bible undoubtedly originated in a mistranslation of a Hebrew word which probably denoted a kind of wild ox with two horns. Though the animal above described is often mentioned by ancient writers, none of them had ever seen one, and modern naturalists generally disbelieve that any such ever existed. The rhinoceros with a single horn does not correspond in any other particular to the description. The sea unicorn is the narwhal.

UNICORN PLANT. See MARTYNIA.

UNION, the name of 16 counties in the United States. **I.** A N. E. county of New Jersey, bounded N. W. by Passaic river, E. by Staten Island sound and Newark bay, and S. partly by Rahway river, and drained by Elizabeth river and several small streams; area, 101 sq. m.; pop. in 1870, 41,859. The surface is nearly level, and the soil generally fertile. It is traversed by the New Jersey, the New Jersey Central, and other railroads. The chief productions in 1870 were 5,339 bushels of wheat, 4,215 of rye, 94,618 of Indian corn, 36,948 of oats, 61,544 of potatoes, and 114,763 lbs. of butter. There were 1,428 horses, 2,780 milch cows, 899 other cattle, 460 sheep, and 1,116 swine. There were 315 manufacturing establishments, with $3,570,450 capital, and an annual product valued at $5,986,512. The principal manufactories were 34 of carriages and wagons, 1 of cars, 2 of cordage and twine, 1 of cutlery and edge tools, 7 of wagon material, 5 of iron, 3 of machinery, 3 of floor oil cloth, 1 of paving materials, 5 of sash, doors, and blinds, 9 flour mills, 3 bleaching and dyeing establishments, and 1 straw goods bleachery. Capital, Elizabeth. **II.** A central county of Pennsylvania, bounded E. by the West branch of the Susquehanna river, and drained by Penn's, Buffalo, and White Deer creeks; area, about 250 sq. m.; pop. in 1870, 15,565. Spurs of the Alleghany range traverse a large part of the county; the soil along the streams is very rich. Iron ore, bituminous coal, and limestone abound. The chief productions in 1870 were 262,639 bushels of wheat, 297,513 of Indian corn, 318,154 of oats, 75,374 of potatoes, 265,936 lbs. of butter, and 19,542 tons of hay. There were 3,271 horses, 3,565 milch cows, 3,305 other cattle, 2,639 sheep, and 6,128 swine; 2 manufactories of agricultural implements, 1 of boots, 12 of carriages and wagons, 2 of pig iron, 2 of iron castings, 8 tanneries, 1 planing mill, 4 saw mills, and 1 woollen mill. Capital, Lewisburg. **III.** A S. county of North Carolina, bordering W. and S. on South Carolina, drained by Lynches creek and branches of the Catawba and Yadkin rivers; area, about 350 sq. m.; pop. in 1870, 12,217, of whom 2,694 were colored. The surface is generally hilly, and the soil in some parts fertile. Granite and slate abound, and excellent stone for hones and whetstones is found. Gold mines of some value have been worked. The chief productions in 1870 were 79,934 bushels of wheat, 203,032 of Indian corn, 72,308 of oats, 16,945 of sweet potatoes, 75,096 lbs. of butter, 8,262 of tobacco, 12,444 of wool, and 1,196 bales of cotton. There were 1,624 horses, 3,501 milch cows, 4,735 other cattle, 8,973 sheep, and 12,163 swine. Capital, Monroe. **IV.** A N. county of South Carolina, bounded E. by Broad river and S. by the Ennoree, and intersected by the Pacolet and Tyger rivers; area, 500 sq. m.; pop. in 1875, 21,965, of whom 12,505 were colored. The surface is hilly, and the soil fertile. Iron ore and granite abound, and gold was formerly mined. It is intersected by the Spartanburg and Union railroad. The chief productions in 1870 were 36,286 bushels of wheat, 314,981 of Indian corn, 18,491 of oats, 30,610 of sweet potatoes, 92,094 lbs. of butter, 6,562 of wool, 5,282 of tobacco, and 8,537 bales of cotton. There were 1,674 horses, 1,839 mules and asses, 3,446 milch cows, 4,935 other cattle, 4,550 sheep, and 12,666 swine; 15 flour mills, and 2 iron works. Capital, Unionville. **V.** A N. county of Georgia, bordering on North Carolina, and drained by the head streams of the Hiawassee and Tocoa rivers; area, about 400 sq. m.; pop. in 1870, 5,267, of whom 114 were colored. It is traversed by the Blue Ridge. The highlands are well adapted to pasturage. Iron, marble, and granite are found, and there were formerly profitable gold mines. The chief productions in 1870 were 7,681 bushels of wheat, 10,632 of rye, 139,127 of Indian corn, 12,099 of oats, 90,098 of sweet potatoes, 50,155 lbs. of butter, 12,458 of wool, 20,268 of tobacco, and 225 tons of hay. There were 800 horses, 1,622 milch cows, 3,008 other cattle, 6,345 sheep, and 9,723 swine. Capital, Blairsville. **VI.** A N. county of Mississippi, drained by the head waters of the Tallahatchie river; area, about 400 sq. m. It has been formed since the census of 1870. The surface is generally level and the soil productive. Cotton, grain, sweet potatoes, &c., are grown. Capital, New Albany. **VII.** A N. parish of Louisiana, bordering on Arkansas, bounded E. by the Washita river, and intersected by Bayou D'Arbonne and other affluents of that stream; area, about 1,000 sq. m.; pop. in 1875, 12,158, of whom 4,667 were colored. The surface is moderately hilly, and the soil sandy and fertile. The Washita and D'Arbonne are navigable for steamboats. The chief productions in 1870 were 230,282 bushels of Indian corn, 50,445 of sweet potatoes, 28,800 lbs. of butter, and 6,675 bales of cotton. There were 1,400 horses, 1,138 mules and asses, 2,741 milch cows, 6,246 other cattle, 5,502 sheep, and 20,175 swine. Capital, Farmersville. **VIII.** A S. county of Arkansas, bordering on Louisiana, bounded N. E. by the Washita river, and drained by several of its tributaries; area, about 1,230 sq. m.; pop. in 1870, 10,571, of whom 4,896 were colored. The surface is hilly, and the soil fertile. The chief productions in 1870 were 232,038 bushels of Indian corn, 9,308 of peas and beans, 56,623 of sweet potatoes, 44,471 lbs. of butter, and 6,181 bales of cotton. There were 1,290 horses, 1,007 mules and asses, 3,071 milch cows, 4,973 other cattle, 4,697 sheep, and 14,810 swine. Capital, El Dorado. **IX.** A N. E. county of Tennessee, intersected by Clinch river, and bounded N. by Powell's river; area, about 400 sq. m.; pop. in 1870, 7,605, of whom 214 were colored. The surface in the north and centre is mountainous, and in other parts hilly, and the soil adapted to grazing. Iron and lead are found. The chief productions in 1870 were 29,615 bushels of wheat, 168,579 of Indian corn, 69,799 of oats, 53,470 lbs. of butter, 10,673 of wool, and 14,169 of tobacco. There were 1,451 horses, 1,264 milch cows, 1,987 other cattle, 6,326 sheep, and 6,971 swine. Capital, Maynardville. **X.** A N. W. county of Kentucky, separated from Indiana and Illinois by the Ohio river, and drained by Tradewater and Highland creeks; area, 350 sq. m.; pop. in 1870, 13,640, of whom 2,574 were colored. The surface is undulating or hilly, and the soil fertile. Bituminous coal is abundant, and there are several sulphur and chalybeate springs. The chief productions in 1870 were 82,892 bushels of wheat, 771,186 of Indian corn, 34,398 of oats, 69,731 lbs. of butter, 19,402 of wool, and 2,096,260 of tobacco. There were 2,800 horses, 2,130 milch cows, 4,958 other cattle, 7,816 sheep, and 14,976 swine; 3 flour mills, and 1 woollen mill. Capital, Morganfield. **XI.** A central county of Ohio, drained by affluents of Scioto river; area, 445 sq. m.; pop. in 1870, 18,730. The surface is level and the soil fertile. It is intersected by the Cleveland, Columbus, Cincinnati, and Indianapolis, and the Atlantic and Great Western railroads. The chief productions in 1870 were 208,660 bushels of wheat, 808,275 of Indian corn, 156,436 of oats, 60,341 of potatoes, 451,407 lbs. of butter, 43,654 of cheese, 390,281 of wool, and 30,027 tons of hay. There were 6,876 horses, 5,073 milch cows, 9,106 other cattle, 75,924 sheep, and 19,252 swine; 11 manufactories of carriages and wagons, 5 flour mills, 1 woollen mill, 1 distillery, 2 planing mills, and 14 saw mills. Capital, Marysville. **XII.** A S. E. county of Indiana, bordering on Ohio, drained by the East fork of Whitewater river; area, 168 sq. m.; pop. in 1870, 6,341. The surface is generally undulating and the soil very fertile. The Cincinnati and Indianapolis Junction railroad traverses it. The chief productions in 1870 were 261,895 bushels of wheat, 417,555 of Indian corn, 59,400 of oats, 16,527 of potatoes, 160,540 lbs. of butter, 13,514 of wool, and 2,699 tons of hay. There were 2,469 horses, 1,884 milch cows, 3,378 other cattle, 4,215 sheep, and 16,955 swine; 1 manufactory of agricultural implements, 4 of carriages and wagons, 2 planing mills, 3 saw mills, 1 woollen mill, and 9 flour mills. Capital, Liberty. **XIII.** A S. county of Illinois, bounded W. by the Mississippi; area, 320 sq. m.; pop. in 1870, 16,518. The surface is undulating and the soil fertile. Iron ore, lead, chalk, bituminous coal, porcelain clay, alum, and copperas are found. It is intersected by the Illinois Central railroad. The chief productions in 1870 were 180,231 bushels of wheat, 679,753 of Indian corn, 124,473 of oats, 95,352 of Irish and 75,052 of sweet potatoes, 93,545 lbs. of butter, 24,653 of wool, and 22,291 of tobacco. There were 3,919 horses, 2,907 milch cows, 5,127 other cattle, 9,342 sheep, and 25,145 swine; 5 manufactories of agricultural implements, 9 of carriages and wagons, 1 of lime, 1 of stone and earthen ware, and 12 flour mills. Capital, Jonesborough. **XIV.** A S. W. county of Iowa, drained by the head waters of the Platte and Grand rivers; area, 432 sq. m.; pop. in 1870, 5,986. The surface is level or undulating, and the soil fertile. The Burlington and Missouri River railroad passes through it. The chief productions in 1870 were 58,217 bushels of wheat, 259,063 of Indian corn, 65,145 of oats, 27,707 of potatoes, 92,797 lbs. of butter, 19,622 of wool, and 9,817 tons of hay. There were 2,058 horses, 1,557 milch cows, 3,119 other cattle, 4,675 sheep, and 5,231 swine. Capital, Afton. **XV.** The N. E. county of Oregon, bounded N. by Washington territory and E. by Idaho, separated from the latter by Snake river, and watered by Grand Ronde and Powder rivers; area, 4,550 sq. m.; pop. in 1870, 2,552, of whom 45 were Chinese. The Blue mountains are on the W. border, and the surface is generally elevated, three fourths of it consisting of mountains and hills, the former covered with forests of pine, larch, and fir, and the latter with pasturage. The valley of the Grand Ronde is large and very productive. Gold, silver, and copper are found, and some mines are in operation. The chief productions in 1870 were 61,335 bushels of wheat, 69,660 of oats, 29,666 of barley, 26,877 of potatoes, 8,154 lbs. of wool, 84,020 of butter, and 6,752 tons of hay. There were 2,204 horses, 3,585 milch cows, 4,328 other cattle, 2,791 sheep, and 5,270 swine; 5 flour mills, and 4 saw mills. Capital, La Grande. **XVI.** The S. E. county of Dakota, bordering on Iowa and Nebraska, and lying between the Big Sioux and Missouri rivers; area, about 380 sq. m.; pop. in 1870, 3,509. The Dakota Southern railroad passes through the S. part. The river bottoms are very fertile. The chief productions in 1870 were 89,618 bushels of wheat, 78,550 of Indian corn, 55,170 of oats, 9,019 of potatoes, and 100,010 lbs. of butter. There were 1,005 horses, 4,238 cattle, 350 sheep, and 933 swine; 1 flour mill, and 4 saw mills. Capital, Elk Point.

UNION CHRISTIAN COLLEGE, a seat of learning at Merom, Sullivan co., Indiana, midway between Terre Haute and Vincennes, on the Wabash river. It was incorporated in 1859, and its buildings, erected at an expense of $50,000, are on a bluff about 200 ft. high. The college edifice is of brick, 109 ft. long, 65 ft. broad, 83 ft. to floor of cupola, and 128 ft. to top of central spire. It is four stories high, and comprises 26 commodious apartments. Both sexes are admitted as students. There are five departments: academic, business, musical, scientific, and classical. There are seven instructors and 170 students. The endowment is $100,000. Disabled soldiers receive instruction free. The presidents of the college have been the Rev. N. Summerbell, D. D., the Rev. Thomas Holmes, D. D., and the Rev. T. Corwin Smith, A. M. The institution is under the control of the Christian connection.

UNION UNIVERSITY, an institution of learning in the state of New York, comprising Union college with its preparatory classical institute and school of civil engineering in Schenectady, and the medical college, the law school, and the Dudley observatory in Albany. Union college was incorporated by the regents of the university of the state of New York in 1795. It was the second college incorporated in the state, and the first north of the city of New York and west of the Hudson river. It received its name from the circumstance that several religious denominations coöperated in its organization. The first president was the Rev. John Blair Smith of Philadelphia, who resigned in 1799, and was succeeded by Jonathan Edwards the younger. The latter died in 1801, and the Rev. Jonathan Maxcy, then president of Brown university, was chosen president in 1802. He was succeeded in 1804 by the Rev. Eliphalet Nott, who held the office more than 61 years, till his death in 1866. The Rev. Laurens P. Hickok, who had long acted as vice president, was elected his successor, but resigned in 1868. The Rev. Charles A. Aiken succeeded Dr. Hickok in 1869, and resigned in 1871, when the Rev. Eliphalet Nott Potter, grandson of Dr. Nott, was elected to the office, which he still holds (1876). The college lands comprise more than 200 acres, a large part of which, being admirably adapted to ornamental purposes, is reserved for a college park, while the remainder has been put under cultivation for a school of agriculture. The college buildings comprise, besides the memorial hall, a gymnasium, chapel, and library. Besides a preparatory department, the college has a classical, a scientific, and an eclectic course, and provides special instruction in the oriental languages. There is also a special school of civil engineering, founded in 1845. In 1875–'6 there were 18 instructors and 175 students in the college, and 4 instructors and 35 students in the school of civil engineering. The college has a library of 18,000 volumes, and valuable philosophical apparatus and collections in natural history. Numerous scholarships have been founded for the benefit of indigent students. Since 1871 the college has received gifts amounting to more than $250,000. Union college acquired by its charter full university powers, but the creation of post-graduate institutions in Schenectady was not found practicable. In 1873 the institutions above named were united under the charter and board of trustees of Union college, but each retains its respective rights, powers, and corporate existence. The general management of the university is vested in a board of governors consisting of the permanent trustees of Union college and representatives from each of the post-graduate departments. The medical college was established in 1838, and in 1876 had 16 instructors and 123 students. The museum of the college is one of the most valuable institutions of the kind in the country. Many of the professors are connected with the Albany hospital, to the cliniques, lectures, and practice of which the students of the college are admitted without charge. The law school was organized in 1851, and in 1876 had 6 instructors and 93 students. The Dudley observatory was incorporated in 1852 and inaugurated in 1856. It was named in honor of Charles E. Dudley, from whose widow the institution has received gifts and a bequest amounting to more than $105,000. Over $100,000 has been expended on the buildings, instruments, grounds, &c., and $70,000 invested as a permanent fund for the support of the institution. There is a meteorological department connected with it.

UNITARIANISM, in Christian theology, the general name for the class of opinions rejecting the doctrine of the Trinity, and asserting the absolute unity of God. The term as defining a belief denies the deity of Christ and his equality with God the Father, but does not reject his divinity, or any exalted rank consistent with his subordination to God. The denial of the deity of Christ naturally led to the rejection of the doctrine of total depravity and moral inability, and of the necessity of a vicarious atonement. But this rejection is more or less absolute according to the views of individuals, some Unitarians accepting the doctrine of the fall, but denying that its consequences destroy the innate rectitude of human nature; and in respect of the atonement Unitarian belief ranges from a modified conception of the redeeming office of a Saviour to the opinion that his mission was solely that of a teacher and exemplar. Beyond these beliefs Unitarianism does not formulate a special creed, but leaves the largest latitude to individual opinion. Some Unitarians regard the gospel as designed by the Deity for the redemption of a fallen race; others as a recognition of natural religion, with precepts, truths, laws, motives, and hopes, exalting individual responsibility in character and life. Baptism and the Lord's supper are generally recognized rites, and in some congregations such festivals as Easter and Christmas are commemorated. Unitarians affirm that their belief is simply a return to the primitive Christian doctrine; that the teaching of Christ and his apostles as conveyed in the New Testament strictly conformed to the Hebrew tenet of the absolute unity of God; that for more than a century the early Christians were taught and believed this tenet; that this belief was first impaired by the speculations of the Alexandrian and Platonic schools on the mode of the divine existence and manifestations; and that the Trinitarian dogma obtained acceptance through the coöperating influences of ecclesiastical authority and imperial dictation. It is also asserted, as a matter of history, that an earnest opposition to the doctrine of the Trinity in its initiatory and developed formularies opened the most bitter controversy in the early church; and that through the successive centuries there has been an unbroken line of individual and associated believers, who as Unitarians, however differing in other points of controversy, have stood together in their opposition to Trinitarianism.—Discussions on the deity of Christ were simultaneous with the earliest speculations on the Logos. Toward the close of the 2d century Theodotus and Artemon founded schools in Rome, and nearly contemporary were Beryllus and Praxeas, who taught in the same city, and Noëtus in Smyrna. In the 3d century Sabellius announced his doctrine. Arianism originated in the 4th century, and was the parent of Socinianism, which was the progenitor of the later Unitarianism. All these teachers held to the belief in the indivisible unity. Their differing views in respect of other doctrines, and the varying shades of opinion adopted by their disciples as to the degree of elevation to be ascribed to Christ as an inspired teacher, an infallible guide, an impeccable being, and a perfect human example, are shown in the articles Arianism, Arius, Noëtians, Sabellius, and Socinus. For a long time before the reformation there was in Italy much dissent from the Trinitarian tenet. The reformation developed the extent of this dissent, and its adherents were driven from the country. At the same time Ludwig Hetzer, Johann Denk, and Sebastian Frank in Germany, and Claudius in Switzerland, preached monotheism and the simple humanity of Christ. In the 16th century Unitarianism was also widely disseminated in Holland and France. About 1549 Lælius Socinus came from Venice to Zürich. In 1553, for his disbelief in the Trinity and other opinions, Michael Servetus was burned at the stake in Geneva, and after his death the Swiss Anabaptists and those who rejected the Trinity were called Servetists. (See Servetus.) In 1563 Bernardino Ochino published in Zürich his dialogues discussing the doctrine of the Trinity. Contemporary teachers in Geneva were Matteo Gribaldi and Giorgio Blandrata. A few years later Giovanni Valentino Gentilio, a Servetist, was beheaded at Bern. In 1577 Faustus, the nephew of Lælius Socinus, who had inherited the writings of his uncle, proclaimed in Basel that the Trinity was a pagan doctrine. With many others he took refuge in Poland, and his writings were published in Raków. Several exiles settled at Pinczów, and were known as Pinczovians. After years of prosperity in Poland, the Lublin church was broken up in 1627, the Raków school was destroyed in 1638, and later the decree making death the penalty for professing Arianism drove many into the abandonment of their belief; others went to Transylvania, Prussia, Silesia, and the Netherlands; and at the end of the century Unitarians in Europe, as a body, were known only in Transylvania.—In England there are traces of Unitarianism coeval with the reformation. In the time of Edward VI., George Van Paris, for denying the divinity of Christ, was burned at Smithfield, as were Francis Wright at Norwich in 1588, and Bartholomew Legate in Smithfield and Edward Wightman in Lichfield in 1612. John Biddle (1615–'62), by his publications, preaching, and foundation of a sect called Biddellians, earned the title of "the father of English Unitarians." (See Biddle, John.) In 1640 the synods of London and York directed a special canon against Socinianism. In 1652 the Racovian (Raków) catechism was burned in London. According to Dr. Owen, the denial of the divinity of Christ was in 1655 common throughout England. Before the close of the 17th century Unitarians had places of worship in London. Milton's Arianism was completely established after his death. Locke indirectly favored Unitarian views. In 1705 there were "troops of Unitarian and Socinian writers." Thomas Firmin disseminated Unitarian doctrines within the establishment. Evelyn revived Arianism in Dublin, and afterward preached it in London; and Hartley's "Observations on Man" gave rise to the school of which Joseph Priestley was the head. The growth of the denomination warranted the foundation in 1825 of the British and foreign Unitarian association, which has regularly held its anniversaries in London, celebrated its semi-centennial in 1875, and is devoted to the dissemination of books and tracts, to limited missionary efforts, to philanthropic labors, and the help of feeble Unitarian societies.—From the first settlement of the New England colonies there were modifications of the Puritanic creed which assumed the phases of moderate Calvinism, Arminianism, and Arianism. In 1785 the congregation of King's chapel, Boston, eliminated Trinitarianism and the direct worship of Christ from the "Book of Common Prayer." In 1805 a Unitarian was made professor of divinity at Cambridge. In 1815 the controversy between Dr. Channing and Dr. Worcester resulted in the separation of the Unitarians from the Congregationalists, and the establishment of a sect. The ministers of a large number of the Congregational churches of Boston and vicinity and throughout the state with their flocks joined the movement. Harvard college was in their hands, and still remains so. In 1825 the American Unitarian association was organized in Boston, where it celebrated its semi-centennial in 1875. Its general purposes are similar to those of the British and foreign association. It has observed its anniversaries by public meetings, which have afforded opportunities for displaying such denominational zeal and promoting such interests as are consistent with the spirit and objects of the association. Under the name of the "National Conference of Unitarian and other Christian Churches," a considerable number of congregations and religious and benevolent societies are represented by ministers and delegates in biennial gatherings. The organization of the conference is of the most informal character, and its chief purpose is to afford opportunities for discussion, counsel, and advice on practical religious interests.—The "Unitarian Year Book" for 1876 estimates the total number of churches and societies in the United States at 362. In England the Unitarians rank with the first among the minor religious bodies, and their influence is increasing, especially in London and in the manufacturing districts. The principal churches are in London, Liverpool, Manchester, Birmingham, and Sheffield. Among the Scotch-Irish population in the north of Ireland there are more than 40 congregations, the most important being in Belfast; and there is a "North of Ireland Unitarian Society," besides the "Irish Unitarian society." There are also South Wales and Scotch Unitarian associations, but the number of congregations in Scotland is small. In London the Unitarians have an extensive Sunday school association, and the Manchester New college, removed from Manchester in 1857. The "Memorial Hall" was in 1865 erected for a separate Unitarian college in the city of Manchester, and students from the Unitarian denomination are admitted to the Presbyterian college at Carmarthen, Wales. Several of the British colonies offer a new field for Unitarianism, especially Australia, where the most influential churches are at Adelaide, Melbourne, and Sydney.—The total number of Unitarians in English-speaking communities all over the world was estimated in 1876 at 1,000,000, besides great numbers sympathizing with the humanitarian elements of Unitarianism, though nominally belonging to other denominations. The persecution of the Unitarians in Hungary and Transylvania, which took place mainly after the annexation of the latter country to Austria in 1713, ceased toward the close of the 18th century, owing to the tolerant policy of the emperor Joseph II. The Transylvanian Unitarians are the only members of that persuasion who are governed by an ecclesiastical council and a bishop. They have a great Unitarian college at Klausenburg, besides other institutions. They have over 100 small congregations with nearly 60,000 members, chiefly Szeklers, and their number is steadily increasing. A meeting of Hungarian, American, and English Unitarians, held at Buda-Pesth, June 15, 1873, in connection with the national Transylvanian convention at Klausenburg, favored the employment of a larger number of teachers in the Unitarian institutions of that city, and the establishment of a church in the capital of Hungary.

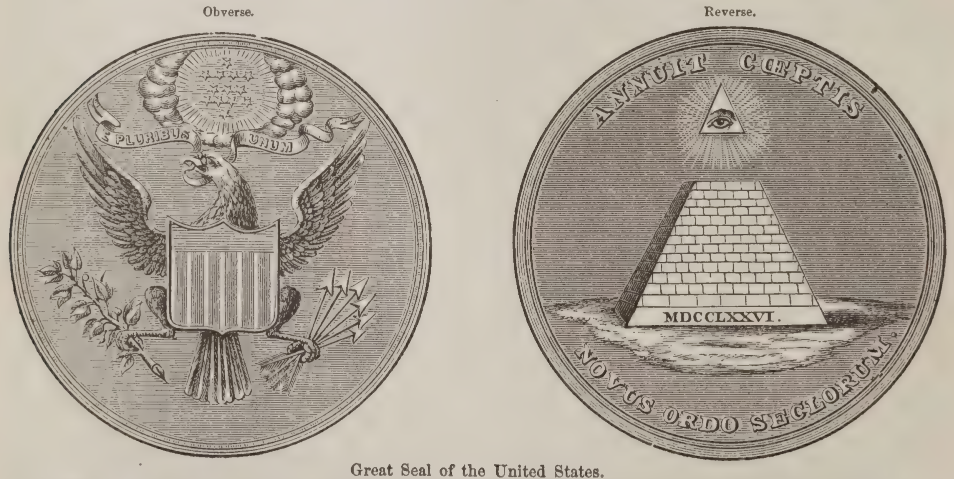
UNITAS FRATRUM. See Moravians.

UNITED BRETHREN IN CHRIST, a Protestant church, frequently confounded with the Moravians, with whom, however, they have no ecclesiastical connection. They arose among the Germans in Pennsylvania about 1760. In 1752 Philip William Otterbein, a missionary of the German Reformed church, sent out to America by the synod of Holland, began to preach in Lancaster, Pa., but, soon becoming convinced that he was not himself converted, rested not until he experienced what he regarded as the new birth. This new experience led him to institute meetings during the week for prayer and religious conference, and he also held in various places outside of his pastoral charge what were called "great meetings." To one of these, held at Isaac Long's in Lancaster co., all persons who had experienced a change of heart, without respect to their ecclesiastical relations, were especially invited. A large assembly, in which Lutherans, Reformed, Mennonites, Dunkers, Amish, and Moravians were represented, convened; and among the number was found Martin Boehm, a Mennonite preacher, who had also some time before obtained what he deemed the new life. At the conclusion of a remarkably effective sermon by Boehm, Otterbein arose, embraced him, and exclaimed, "We are brethren!" This was the origin of the name of the new church. Otterbein and Boehm labored together for more than 50 years, and as the calls for preaching became numerous, laymen selected from the converts were licensed to preach. These laborers at first held conferences at the great meetings; but when this became impracticable, annual conferences were appointed, where preachers were licensed, examined, disciplined, and directed in their labors. (See OTTERBEIN, PHILIP WILLIAM.) The first annual conference met in 1800, the first general conference in 1815. In 1875 this denomination had 43 annual conferences, 4,010 organized churches, 1,967 ministers, and 136,076 members. It has at Dayton, Ohio, an extensive printing establishment, where several periodicals and a variety of books are issued in English and German. The aggregate circulation of the periodicals published by this church, in July, 1874, was 181,500 copies. At the quadrennial meeting of the general conference in 1873, the receipts of the book concern during the preceding four years were reported at $322,370, the expenditures at $318,628, and the excess of assets over liabilities at $96,525. In 1875 the church owned ten institutions of learning, viz.: Lebanon Valley college, Annville, Pa.; Otterbein university, Westerville, O.; the Union Biblical seminary, Dayton, O.; Hartsville university, Hartsville, Ind.; Green Hill seminary, Poolsville, Ind.; Roanoke seminary, Roanoke, Ind.; Westfield college, Westfield, Ill.; Western college, Western, Iowa; Lane university, Lecompton, Kansas; and Philomath college, Philomath, Oregon. The United Brethren in Christ are Arminian in theology, and supply their churches with preaching on the itinerant plan. They have quarterly, annual, and general conferences. The highest ecclesiastical body is the general conference, which meets every four years. Until 1873 it consisted exclusively of clerical delegates; but in that year it adopted the principle of lay delegation, and the church ratified it when it was submitted to a general vote. It elects bishops (in 1873, four) for a term of four years, and assigns to each a district. No slaveholder, no adhering member of any secret combination, and no manufacturer, seller, or drinker of intoxicating liquors can be a member of the church. They regard a change of heart as indispensable to membership. Baptism is administered by either sprinkling, pouring, or immersion, each member being permitted to exercise his own judgment in regard to the mode; infants are baptized when it is desired. Open communion is practised. Until about 1825 the United Brethren in Christ confined their labors almost exclusively to persons speaking German, but most of the communicants now speak English. Being one of the most outspoken anti-slavery churches, they had before the civil war hardly any congregations in the southern states; since then they have established several there. In some of the western states this church is among the largest denominations. Foreign missions have been established in Africa and Germany. —See "History of the United Brethren in Christ," by G. Lawrence.

UNITED EVANGELICAL CHURCH, an ecclesiastical denomination in Germany, which arose in 1817 out of a union of the Lutheran and Reformed churches. Attempts at uniting these two churches were made as early as 1529, when leading theologians of both schools held a conference at Marburg. These attempts were often renewed, and other religious conferences between theologians of the two denominations were held at Leipsic in 1631, and at Cassel in 1661. In 1703 Frederick I. of Prussia convened several Lutheran and Reformed theologians at Berlin, to discuss the practicability of a union. He erected union churches at Berlin and Charlottenburg, and had the orphans of the two denominations brought up in the same establishments; but the Lutheran clergy successfully resisted the progress of these schemes. A "Plan of Union" proposed by Klemm and Pfaff, theologians of Tübingen (1710–1722), met with little favor. Frederick William I. issued several decrees designed to promote a union. The rise of rationalism, toward the close of the 18th century, disposed the theologians generally in favor of a union of the two churches, whose distinctive tenets, it was generally admitted, had but few believers among the clergy of either. Schleiermacher proposed to establish at first only an external church unity, and to leave the controversies of scientific theology open to discussion. The tercentenary of the reformation in 1817 led at length to the practical establishment of the union, which, however, in the opinion of many of its advocates, was to consist at first only in the establishment of a common church government and the common celebration of the Lord's supper. The leadership in this movement was assumed and has ever since been maintained by the government of Prussia. The clergy of Berlin issued a declaration in favor of the union, and a circular of the minister of the interior confirmed it, and decreed that the united church should bear henceforth the name Evangelical Christian church. It was thought that the union would be gradually and peaceably consummated by an agreement respecting a constitution, church property, and ordinary usages. It was also decided that the Lord's supper should be celebrated by a mere breaking of the bread and a faithful recitation of the words used in the original institution. For several years this work appeared to be in process of accomplishment in the several ecclesiastical corporations, sometimes by public enactments and sometimes as the government directed, by a practical acceptance of the breaking of the bread and an acknowledgment of the authorities of the united church; but it was considerably disturbed by the introduction of a new liturgical book, the *Agenda*. A theological commission, appointed to compose such an instrument, accomplished nothing. The king then published an *Agenda*, which had been introduced by his cabinet (1822) into the court church, gave orders that it should be introduced into the garrison churches of his kingdom, and recommended it to all the congregations of the realm, instead of the conflicting and arbitrary forms which had previously been used in the different provinces. Many objections were raised against the *Agenda*, especially by the strict Lutherans; and when in 1834 a royal decree was issued ordering its introduction into all non-united as well as united congregations of the kingdom, a number of strict Lutherans seceded from the national church. For several years the government endeavored by the suspension of ministers to coerce them back into the national church; but in 1845 Frederick William IV. conceded liberty of worship. They then organized an independent Lutheran church, which numbered in 1871 about 20,000 members. All the rest of the former Lutheran and Reformed churches of Prussia nominally connected themselves with the United Evangelical church. But there was great difference of opinion as to the nature and extent of the union by which the United Evangelical church had been called into existence. One party, generally called the confederalists, under the leadership of Prof. Hengstenberg and Dr. Stahl, maintained that the union consisted in a mere external confederation and subjection to the same general church government; that the individual churches remained Lutheran, Reformed, or (if they have expressly adopted the union) United; and that if the right of adhering to the old standards of the Lutheran confession should be curtailed, it would become the duty of the party to secede. A second party, commonly called the consensus party, took for its doctrinal basis the Bible and the common dogmas of the Lutheran and Reformed confessions. It controlled the theological faculties of most of the universities, not only in Prussia, but in the other German states. Among its leading men were Nitzsch, Twesten, Hoffmann, Niedner, Tholuck, Julius Müller, Jacobi, Dorner, Lange, Liebner, Stier, Ullmann, Umbreit, Ebrard, Herzog, and Rothe. A third party, frequently designated as the union party, rejected the authoritative character of the old symbolical books of both the Lutheran and Reformed denominations, and based themselves on the Bible simply, claiming at the same time the right of subjecting the authenticity of the Old and New Testaments to critical examination. This party embraced many of the disciples of Schleiermacher, the school of Tübingen, and liberal divines of different shades of opinion. The second and third parties agreed in asking for the introduction of a presbyterian church constitution, embracing district, provincial, and general synods; but their exertions were vigorously resisted by the confederalists. Frederick William IV., who repeatedly declared his wish to restore full self-government to the national church, convoked in 1846 a general synod, in order to complete her organization. The work was interrupted by the revolution of 1848, but resumed in 1856 by another general conference. While the government of Frederick William IV. had strongly favored the first of these three parties, his successor William I. showed an outspoken sympathy with the second. The supreme ecclesiastical council tried to check the manifestations of the Lutheran clergymen and societies who endeavored to maintain the strictly denominational character of the formerly Lutheran section of the church. The annexation to Prussia of Schleswig-Holstein and Hanover, both of which countries had a Lutheran state church that had never accepted the union, created new difficulties in the way of carrying it through. A radical change in the constitution of the church began in 1874, when the state government, in accordance with the laws passed in 1873, substituted the principle of ecclesiastical self-government for that of the consistorial administration heretofore exercised by the state. Church councils were elected in all congregations, and circuit synods, consisting of delegates of the congregations, were convoked. In January and February, 1875, provincial synods, composed of delegates of the circuit synods, met in all the eight old provinces of Prussia (those belonging to Prussia before the annexations of 1866), and in November and December an extraordinary general synod, formed of delegations of the eight provincial synods and members appointed by the king, met in Berlin to make all necessary preparations for a transfer of the government of the church to a regular general synod. The Prussian government makes the utmost exertions to render it possible for the discordant ecclesiastical parties to live peaceably side by side in the national church, but large numbers, especially of the adherents of strict Lutheran principles, may ultimately prefer secession to a continuance of their church communion with parties which they consider heretical.—The example of the king of Prussia in consolidating the Lutheran and Reformed churches into a United Evangelical church was followed in other German states. Thus the union was introduced, either by resolution of synods or by a general vote, in Nassau (1817), the Bavarian Palatinate (1818), Baden (1821), and even in Würtemberg (1827), where the Reformed church had hardly an existence. The union may be considered permanently established in the Bavarian Palatinate and in Baden, in both of which the church has a presbyterian constitution, inclusive of a general synod, which in both churches is unanimous in maintaining the union. Saxony, the bulk of Bavaria proper, Mecklenburg, Brunswick, and several other states were too exclusively Lutheran, Switzerland too exclusively Reformed, to fall in with the movement. In many of the small states the views of the people on the subject of union could not be ascertained, as the church was without a synodal constitution and entirely controlled by the government. The introduction of the synodal constitution, which in 1875 had been completed in the large majority of the Protestant state churches, United Evangelical as well as Lutheran, will ere long define the position of every church in regard to the union. In Austria and France a fusion of the Lutheran and Reformed churches has also many friends, but nothing has been done in the way of practical execution.—See Hering, *Geschichte der kirchlichen Unionsversuche* (2 vols., Leipsic, 1836–'8); Nitzsch, *Urkundenbuch der evangelischen Union* (Bonn, 1853); Julius Müller, *Die evangelische Union* (Leipsic, 1854); Stahl, *Die lutherische Kirche und die Union* (Berlin, 1858).—A branch of the United Evangelical church in the United States was established at St. Louis in 1840, when six German ministers organized an ecclesiastical body called *Evangelischer Kirchenverein des Westens* (Evangelical Church Union of the West). In 1856 this body was divided into three districts, in 1866 it changed its name into "German Evangelical Synod of the West," and in 1870 it reported at the "General Assembly," held in Louisville, 162 ministers, 300 congregations, 12,000 voting members, about 20,000 communicants, and a total population of about 50,000. Independent of this organization, another branch of the United Evangelical church was constituted in 1848 under the name of "Evangelical Synod of North America." In May, 1859, it split into two independent bodies, one of which assumed the name "United Evangelical Synod of the Northwest," and the other "United Evangelical Synod of the East." Both of them united in 1872 with the "German Evangelical Synod of the West," constituting henceforth the fourth and fifth districts of this body. In 1874 the church was redistricted by the general conference held in Indianapolis into seven particular synods; it numbered at this time about 300 ministers and 40,000 communicants. The church has a theological seminary in Warren co., Mo., and another educational institution at Elmhurst, Ill. In 1876 the German language was still exclusively used in all the congregations of this church. It publishes three denominational papers.

UNITED PROVINCES. See Netherlands.

UNITED STATES OF AMERICA, a federal republic in North America, comprising the central portion of the continent and the territory of Alaska, separated from the rest by British Columbia. (See Alaska.) The main portion lies between lat. 24° 30′ and 49° 24′ N. (at the lake of the Woods, W. of which the boundary follows the 49th parallel), and lon. 66° 50′ and 124° 45′ W. It is bounded N. by British America, from which it is in part separated by Lakes Superior, Huron, St. Clair, Erie, and Ontario, with their connecting streams, and the river St. Lawrence (see Canada, vol. iii., p. 672); E. by New Brunswick and the Atlantic ocean; S. by the gulf and republic of Mexico, from which it is partly separated by the Rio Grande; and W. by the Pacific ocean. The British American boundary, according to the war department map (1869), measures 3,540 m.; the Mexican, 1,550 m. The greatest length, from Cape Cod on the Atlantic to the Pacific near the 42d parallel, is nearly 2,800 m., and the greatest breadth, from the N. W. extremity of Minnesota to the southernmost point of Texas, 1,600 m.; general breadth, about 1,200 m. The area, according to Walker's "Statistical Atlas of the United States," is 3,026,494 sq. m. (exclusive of lakes and river surfaces bounding the republic or the single states), of which 827,844 sq. m. belonged



Obverse. Reverse.

Great Seal of the United States.

[The device for the great seal of the United States, as adopted by act of the continental congress on June 20, 1782, and re-adopted by the new congress, Sept. 15, 1789, provided for an obverse and a reverse, substantially as here depicted; but there is no evidence that the reverse was ever made. In the obverse as originally adopted, the eagle held in his sinister talon a bundle of thirteen arrows, and the first seal was thus made; but when, in 1841, a new seal was made to take the place of the old one, which had become worn, only six arrows were put into the eagle's talon. Whether this change, which was unauthorized by law, was made by design or by accident, is not known.]

EASTERN PART.

Engd. by O. J. Stuart, N.Y.

to the republic at the peace of 1783, 1,171,931 sq. m. were added by the Louisiana purchase from France in 1803 (supplemented by the Oregon treaty with Great Britain in 1846), 59,268 sq. m. by the Spanish cession of 1819, and 967,451 sq. m. from Mexico, viz.: 376,133 sq. m. by the annexation of Texas in 1845, 545,783 sq. m. by the treaty of Guadalupe Hidalgo in 1848, and 45,535 sq. m. by the Gadsden purchase in 1853.—The republic is divided into 37 states, one federal district (District of Columbia, ceded by Maryland), nine organized territories, and two unorganized territories (Alaska and Indian territory). By the act of congress of March 3, 1875, Colorado is authorized to frame a constitution and to submit it to a vote of the people in July, 1876, when, in case of its adoption, the president is to issue a proclamation declaring the territory admitted into the Union as a state. A bill for the admission of New Mexico as a state passed the senate March 10, 1876, and is (June 1) pending before the house of representatives. For convenience the states are generally classified by geographers as follows: eastern or New England states, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut; middle states, New York, New Jersey, Pennsylvania, Delaware; southern states, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, Tennessee, Kentucky; western states, Ohio, Michigan, Indiana, Illinois, Wisconsin, Minnesota, Iowa, Missouri, Kansas, Nebraska; Pacific states, California, Oregon, Nevada. Another classification is: Atlantic and Pacific states, those on the Atlantic and Pacific slopes respectively; gulf states, those bordering on the gulf of Mexico; southwestern states, Louisiana, Texas, Arkansas, Missouri, Kansas; northwestern states, Michigan, Wisconsin, Minnesota, Iowa, Nebraska; central states, Ohio, Indiana, Illinois, Kentucky, Tennessee. The slave states, those in which slavery existed at the outbreak of the civil war, numbered 15, viz.: Delaware, Maryland, Virginia (then including West Virginia), North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, Tennessee, Kentucky, Missouri; the others were known as the free states. Of the states, 13 existed at the formation of the constitution, and 24 have been admitted under its provisions. Of these one (Texas) was an independent republic, four were formed directly from other states (Kentucky from Virginia, Maine from Massachusetts, Vermont from territories claimed by New York and previously also by New Hampshire, and West Virginia from Virginia), and the rest were created from the public domain. The following tables contain a list of the states and territories, with various particulars. The second and third columns of the first give for the original states the date and order of ratification of the federal constitution, for the other states the date and order of admission into the Union, and for the territories the date and order of organization. The areas are taken from the report of the census of 1870. Many of these, as well as the general figures given above, are based mainly on approximative computations. In a few instances slightly different figures have been given in the articles on the states and territories, those in PENNSYLVANIA being the estimate of the state geologist. The aggregate population in the second table includes tribal Indians, as estimated by the superintendent of the census in 1870.

STATES.	Date.	Order.	Area in square miles.	Relative size.	CAPITALS.

A state census was taken in Michigan in 1874, and censuses were taken by 14 states in 1875. The population according to these enumerations, except in Florida, from which the returns have not (June 1, 1876) been received, was as follows: Iowa, 1,350,544; Kansas, 528,437; Louisiana, 857,039 (404,916 white and 452,123 colored); Massachusetts, 1,651,652; Michigan, 1,334,031; Minnesota, 597,407; Nebraska, 246,280; Nevada, 52,540; New Jersey, 1,019,413; New York, 4,705,208; Oregon, 104,920; Rhode Island, 258,239; South Carolina, 925,145 (350,754 white and 574,391 colored); Wisconsin, 1,236,729. According to the census of 1870, there were 52 cities with more than 25,000 inhabitants each, of which 8 had upward of 200,000, 6 from 100,000 to 200,000, 11 from 50,000 to 100,000, and 27 from 25,000 to 50,000. Besides these there are 9 cities which, according to the state censuses named above, contained upward of 25,000 inhabitants each in 1874 or 1875. The table on the next page contains a list of these 61 cities with their population as returned by the United States census in 1870, and the population in 1874 or 1875 of such as are contained in the state censuses.

—With the exception of a small portion of the N. E. coast, the shores on the Atlantic and gulf are low, while those on the Pacific are mostly bold and rocky. The most important indentations on the Atlantic are Passamaquoddy, Frenchman's, Penobscot, Casco, Massachusetts, Cape Cod, Buzzard's, Narragansett, New York, Raritan, Delaware, and Chesapeake bays, and Long Island, Albemarle, and Pamlico sounds; on the gulf, Tampa, Appalachee, Pensacola, Mobile, Galveston, Matagorda, Espiritu Santo, Aransas, and Corpus Christi bays, with those about the delta of the Mississippi; and on the Pacific, San Diego harbor, Monterey bay, San Francisco bay, and the strait of Fuca. The length of coast line, not including indentations of the land, according to the United States coast survey, is 5,715 m., viz.: 2,349 m. on the Atlantic, 1,556 on the gulf of Mexico, and 1,810 on the Pacific. The shore line of the great lakes, according to estimates made in the coast survey office, measures 3,450 m., viz.: Superior, 955; Michigan, 1,320; Huron, 510; St. Clair, 65; Erie, 370; Ontario, 230.—The rivers of the United States may be comprised in four distinct classes: 1. The Mississippi and its affluents, which drain the region between the Alleghanies and the Rocky mountains. The chief of these affluents are: on the east, the Wisconsin, Rock, Illinois, Ohio, Yazoo, and Big Black; on the west, the Minnesota, Des Moines, Missouri, St. Francis, Arkansas, and Red river. Several of these are from 1,000 to 2,000 m. in length, while many of the secondary affluents have courses extending from 300 to 1,000 m. 2. The rivers which rise in the Alleghany chain and flow into the Atlantic. Of these, the most important, beginning at the northeast, are the Penobscot, Kennebec, Merrimack, Connecticut, Hudson, Delaware, Susquehanna, Potomac, James, Roanoke, Neuse, Cape Fear, Great Pedee, Santee, Savannah, and Altamaha, most of which exceed 300 m. in length, and are navigable to a considerable distance from the sea. 3. The rivers of the southern slope, flowing into the gulf of Mexico, the principal of which, E. of the Mississippi, are the Appalachicola, Mobile, and Pearl, and W. of the Mississippi, the Sabine, Neches, Trinity, Brazos, Colorado, Nueces, and Rio Grande (which forms the boundary between Texas and Mexico). 4. The rivers which flow into the Pacific, of which the most important are the Columbia, which has several large affluents; the Sacramento and the San Joaquin, which flow into the bay of San Francisco, and drain the fertile valley between the Sierra Nevada and Coast mountains; and the great Colorado of the West, which has its terminus in the gulf of California, and drains the region between the Wahsatch and Rocky mountains. Besides these may be mentioned the shallow streams of the Great Basin, which have no outlet to the ocean; the Red river of the North, which empties into Lake Winnipeg in British America; the St. Lawrence, which forms part of the boundary between New York and Canada, and discharges the waters of the great lakes and their affluents; the St. John and St. Croix, which form part of the boundary between Maine and New Brunswick; and the St. John's, in Florida. Few countries in the world contain so many lakes as the United States, though these are principally confined to the northern portion. Of the five great lakes, as they are called, the largest bodies of fresh water on the globe, with perhaps the exception of the newly discovered and imperfectly known lakes in the interior of Africa, four, viz., Superior, Huron, Erie, and Ontario, lie on the northern border, partly in the United States and partly in British America, while

† Annexed to Boston in 1874.

Lake Michigan is wholly within the territory of the republic; so is nearly all of Lake Champlain. Near the S. end of the last, in New York, is Lake George, renowned for its beautiful scenery, a feature equally characteristic of other lakes in the neighboring wilderness of the Adirondacks and in New England. Among the last mentioned, the most important are Moosehead in Maine, Winnipiseogee in New Hampshire, and Memphremagog, partly in Vermont and partly in Canada. The central parts of Maine are thickly strewn with lakes of great beauty and considerable size; and in almost every part of New England sheets of water are abundantly found under the designation of ponds, which in Europe from their size and beauty would be classed as lakes. The central and western parts of New York contain several large lakes, the most remarkable of which are Otsego, Oneida, Skaneateles, Cayuga, Seneca, Keuka (formerly Crooked), and Chautauqua. In the southern states lakes of fresh water are rarely found except in Florida, where the principal is Okeechobee, and in Louisiana, where there are many lakes formed by expansions of the numerous rivers. In the states of the northwest, lakes are very numerous in Michigan, Wisconsin, and Minnesota; the great number and size of those in the last form indeed one of its most remarkable geographical features. The most noted on the Pacific slope is Great Salt lake. In the Great Basin, in Utah and Nevada, are many other lakes or sloughs, most of which, like this, are salt. In California and E. Oregon are several similar bodies of water. The area of the United States, with reference to its watersheds, is divided, according to Walker's "Statistical Atlas of the United States," as follows: 1. The Pacific slope, 854,314 sq. m., including the basin of the Columbia, 219,706 sq. m.; Great Basin, 210,274; basin of the Colorado of the West, 264,386; coast basins, 159,948. 2. The Mississippi valley, 1,257,545 sq. m., including the Missouri basin, 527,690 sq. m.; upper Mississippi, 179,635; Ohio, 207,111; Arkansas, 184,742; Red river, 92,721; lower Mississippi, 65,646. 3. The gulf slope W. of the Mississippi, 279,768 sq. m., of which the Rio Grande basin occupies 101,334, and the gulf slope E. of the Mississippi 145,990 sq. m. 4. The Atlantic slope proper, 304,538 sq. m. 5. The basins of the St. Lawrence and Red river of the North, 184,339 sq. m.—The United States is crossed in a general N. and S. direction by two great systems of mountains, the Rocky mountains in the west and the Appalachian or Alleghany chain in the east, between which is the extensive and fertile Mississippi valley. The great mass of the Rocky mountain system is W. of the 105th meridian. Its two main chains are the Rocky mountains proper, extending through New Mexico, Colorado, Wyoming, and Montana, and the Sierra Nevada in California, with its extension, the Cascade range, in Oregon and Washington territory. Between these two chains is a plateau, crossed by numerous mountain ranges, which through its centre E. and W. is from 4,000 to 5,000 ft. high, falling off toward the north and south from that line. The Wahsatch mountains are the most important range of the plateau. They extend S. and S. W. through Utah and S. E. Nevada, and form the E. rim of the Great Basin, the W. rim being the Sierra Nevada. They rise from 4,000 to 6,000 ft. above the plateau, Mt. Nebo being 11,992 ft. high. The Blue mountains in E. Oregon are little known. The most elevated portion of the plateau is between the Wahsatch and Rocky mountains, and embraces the Colorado "parks" and the Laramie plains in Wyoming. The average elevation here is from 7,000 to 9,000 ft., being greatest on the N. edge of the South park, whence there is a gentle decline in either direction. The loftiest portion of the Rocky mountains is in Colorado, where there are many peaks upward of 14,000 ft. high. The Wind River mountains in N. W. Wyoming, and the Bitter Root mountains, forming part of the boundary between Idaho and Montana, are important spurs of this chain. In the Wind River mountains rise the Missouri river, the Green river, forming the main branch of the Colorado of the West, and the Snake, one of the main branches of the Columbia. The Black hills, on the border of Wyoming and Dakota, may be considered an outlying group of the Rocky mountains. The Sierra Nevada and Cascade mountains run nearly parallel with the Pacific coast, from 100 to 150 m. from it. In the former are several peaks more than 14,000 ft. high, Mt. Whitney (14,887 ft.) being the highest in the United States. The Coast range is the westernmost of the Rocky mountain system, running through California, Oregon, and Washington territory, at a distance of from 10 to 50 m. from the coast. It averages from 2,000 to 3,000 ft. in height, but a few peaks rise more than twice as high, and Mt. San Bernardino, the loftiest (which is however not generally considered as belonging to the Coast range), to an elevation of 11,600 ft. The Rocky mountain system embraces an area of nearly 1,000,000 sq. m. It is widest between the 36th and 41st parallels, where the breadth is from 800 to 1,000 m. It is lowest along the 32d parallel, where the greatest elevation is not more than 4,000 ft. The Appalachian chain extends S. W. from Canada to Alabama. It includes among other ranges the Green mountains in Vermont, the Catskills in New York, the Blue Ridge in Virginia, the Black mountains in North Carolina, and as outlying spurs the White mountains in New Hampshire and the Adirondacks in New York. Mt. Washington in the White mountains is 6,293 ft. high (according to Prof. Hitchcock); the loftiest peak of the chain is the Black Dome in the Black mountains, about 6,700 ft. The greatest width of the chain, not including outliers, is 100 m., in Pennsylvania and Maryland. The height of the plain at the base is 500 ft. in New England, and becomes 1,200 ft. S. of Virginia; the W. base in Virginia and Tennessee is from 1,000 to 2,000 ft. high. The Appalachians make their nearest approach to the sea in the Highlands on the Hudson, which are about 30 m. from Long Island sound; in the south the distance from the coast is 200 m. The Atlantic slope, between the Appalachians and the ocean, is in general hilly, with level tracts near the shore, particularly in the south. The great central district between the two mountain systems is a region of prairies and plains, sloping from each toward the Mississippi river, with a gentle southern decline to the gulf of Mexico. A portion in the northeast slopes toward the great lakes, and the basin of the Red river of the North toward the north. The elevation at the base of the Rocky mountains in Montana is 4,091 ft.; at the mouth of the Yellowstone river, on the border of Montana and Dakota, 2,010 ft.; at Denver, Colorado, 5,267 ft.; of the Llano Estacado in Texas and New Mexico, 3,200 to 4,700 ft.; of the source of the Mississippi in Minnesota, 1,680 ft.—Some details of the distribution of the great geological formations over the territory of the Union, and the relations of these to its geography, have already been given in the article Geology, vol. vii., p. 695. It is there stated that the eozoic formations bearing the names of Laurentian, Huronian, Montalban, and Norian make up the Atlantic belt of the Appalachians, extending from E. Canada through New England and E. New York to N. E. Alabama. To these eozoic groups belong the White mountains, the Green mountains, the Adirondacks, the Highlands of New York and New Jersey, the South mountain of Pennsylvania, and its continuation south of the Potomac, the Blue Ridge. The lower levels of E. New England are also, with some exceptions, occupied by eozoic rocks, and the same is true of a broad belt of rolling country between the E. base of the Blue Ridge and the low lands of the coast. In addition to what has been said with regard to the distribution of the various formations over this area, it may be noted that rocks of the Laurentian age extend from the Hudson to the Schuylkill, while further southward Huronian and Montalban rocks prevail, including however a belt of Laurentian in Virginia. Westward from the Adirondacks eozoic rocks, embracing the four great types already mentioned, extend through Canada to N. Michigan and Wisconsin, while southward they reappear in the Ozark mountains of Arkansas, and also in small areas in Missouri. In the Rocky mountains eozoic rocks appear which seem to be identical in their character with those of the Appalachians, but have not yet been critically studied. At the W. base of the Green mountains, and thence extending along the W. flank of the South mountain and the Blue Ridge as far as Georgia, is a series of rocks to which Prof. Emmons gave the name of the Taconic system. He described them as having a total thickness of about 20,000 ft. and consisting of an upper and a lower division; the latter consisting of sandstones and quartzites, followed by a great mass of limestones interstratified with and overlaid by argillaceous and magnesian schists, and destitute of fossils; while the upper division, including sandstones, slates, and limestones, contained a palæozoic fauna supposed by him to be older than that of the Potsdam and calciferous of New York, which latter were declared to overlie unconformably the Taconic system. These views were opposed by most American geologists, and chiefly by Mather, H. D. Rogers, and Logan. According to these authorities, the whole Taconic system represented in a modified condition the middle and upper Cambrian rocks, from the Potsdam to the Oneida. (See Geology, tabular view, vol. vii., p. 694.) Later researches have confirmed the views of Emmons as to the antiquity of a portion of the fauna of the upper Taconic rocks, while the lower Taconic may correspond to the lower Cambrian of Europe, or perhaps to a still earlier period more closely related to the eozoic rocks already noticed. These rocks are important as making up the chief part of the floor of the great Appalachian valley from Lake Champlain to Georgia, a region remarkable for fertility of soil and for the great deposits of brown hematite (limonite) iron ore which belong to the lower Taconic strata. The American subdivisions of the middle and upper Cambrian rocks, from the Potsdam to the summit of the Loraine (or Hudson river) shales, appear in their characteristic forms in the valleys of the Mohawk and the St. Lawrence. From this great plain around the base of the Adirondacks they extend westward to the Mississippi valley, and thence southward as far as Texas. They are also found at intervals along the eastern border of the palæozoic basin as far as Tennessee, but their precise relations to the Taconic rocks along this line are still involved in discussion. The base of the next great palæozoic division, the Silurian proper, is the Oneida, which rests unconformably upon the preceding, and, being a strong and massive sandstone or conglomerate, gives rise to a conspicuous ridge along the eastern border of the basin. It forms the Shawangunk mountains of S. E. New York and the Kittatinny mountain of Pennsylvania, stretching thence southward and bounding the great Appalachian valley on its N. and W. side, while the crystalline rocks of the South mountain and the Blue Ridge enclose it on the south and east. The whole eastern portion of the great palæozoic basin has been much disturbed by undulations of the strata having a general N. E. and S. W. direction, often complicated by fractures with great vertical displacements of the strata, which may be described as upthrows on the N. W. side of the faults. This disturbed region includes the whole of the palæozoic series to the top of the coal, embracing various massive sandstones and conglomerates. As the combined result of these disturbances and the subsequent erosion of the surface, the whole region has been converted into a mountainous belt of parallel ridges, extending along the N. W. side of the great Appalachian valley from the Catskill mountains of New York throughout all its length, and constituting the Alleghany mountain belt, of which the Kittatinny may be considered as the eastern limit. In this disturbed region occur the anthracite and semi-bituminous coal basins of Pennsylvania, Maryland, and Virginia, and the dislocations just alluded to are in repeated instances so great as to bring up the base of the palæozoic series on the N. W. side of the detached areas of coal. To the westward these disturbances become less and less marked, and the Devonian and carboniferous rocks are seen comparatively undisturbed. Further to the west we reach the Cincinnati axis, which is traced from Lake Ontario to N. Alabama, and brings up on a gentle anticlinal the upper Cambrian beds, known in this region as the Cincinnati group, from Cincinnati with some interruptions to Nashville, Tenn. Further southward it sinks beneath the coal formation of Alabama. To the east of this great dividing line extends the Appalachian coal field from Alabama through E. Tennessee, Kentucky, and Ohio, including West Virginia and the W. half of Pennsylvania; while to the west of it are three other palæozoic coal fields, that of Michigan, that of Illinois, including parts of Indiana and western Kentucky, and that west of the Mississippi, extending from Iowa, through Missouri, Kansas, and Arkansas, into Texas. (See Coal.) To the westward of this last coal field are great areas of newer rocks of triassic, Jurassic, cretaceous, and tertiary periods, which extend to the base of the Rocky mountains and beyond. The cretaceous and tertiary strata, after stretching southward through Texas, reach up the Mississippi valley as far as the mouth of the Ohio, eastward along the gulf of Mexico, and thence northward to the coast of Massachusetts, in a belt of gradually diminishing breadth, including Long Island and a part of Martha's Vineyard. The valley of the Mississippi, with the greater part of Florida and a border of varying width along the seaboard, is overlaid with deposits which are regarded as post-tertiary. The whole of these newer strata along the Atlantic region rest in a nearly horizontal attitude on the eozoic and palæozoic rocks. The cretaceous strata are in many parts concealed, but are recognized along the N. portion of Long Island, and pass across New Jersey and N. Delaware to the head of Chesapeake bay. Thence they are exposed at a few points in E. Virginia, the Carolinas, and Georgia, till in the W. part of this state they appear in a broad belt extending through central Alabama and curving northward through N. Mississippi and E. Tennessee. These newer rocks along the Atlantic coast form the tide-water region, and are nowhere affected by the movements which have disturbed the older rocks. What has been called the new red sandstone formation of the Atlantic belt extends in a narrow line from N. Massachusetts along the Connecticut valley to New Haven. It is again continued from the Hudson across New Jersey and Pennsylvania into Virginia, and is found in smaller areas in S. E. Virginia and in North Carolina. From its organic remains this sandstone is regarded as lower mesozoic, probably including the triassic and Jurassic periods. In Virginia and in North Carolina it includes beds of workable coal, which rest upon the eozoic crystalline rocks. In a similar relation there is a considerable area of coal-bearing rocks in Rhode Island and Massachusetts, which are however of palæozoic age like the coals of the Appalachian field. Small areas of fossiliferous lower Cambrian, Silurian, and Devonian are found in various localities among the crystalline rocks of New England. Over the N. E. portions of the United States is widely spread the so-called drift formation or diluvium of post-pliocene age (see Diluvium), consisting of unstratified bowlder drift and modified or stratified drift. The southern limit of these deposits and of the marks of glaciation is about lat. 40° N. The crystalline rocks to the north of them present hard, smoothly worn, or striated surfaces, except in some protected localities; but further southward they are generally decayed or softened to a greater or less depth, sometimes 100 ft. or more, from a process of chemical change. The great elevated western or Rocky mountain region differs widely in general features from that just described. Upon the broad area of crystalline rocks, which reproduce on a grand scale the characteristics of the Appalachian belt, are found all the members of the palæozoic series, overlaid for the most part by older mesozoic rocks and by a great thickness of cretaceous and tertiary strata, in which each one of the three great divisions of the latter is well represented. These newer rocks constitute vast arid plains, and in the cretaceous and eocene or lower tertiary strata the great coal deposits of this region are found. These strata have been disturbed by great faults, penetrated and overflowed by vast volumes of eruptive rocks, and subjected to erosion on a grand scale. The crystalline rocks which bound the great palæozoic basin of the United States to the east and the north are rich in ores of iron, and include also gold, copper, lead, nickel, and chrome. The native copper of the S. shore of Lake Superior belongs to a peculiar group of strata, unknown elsewhere, lying at the very base of the palæozoic series. Various horizons in the palæozoic rocks, up to the coal inclusive, abound in ores of iron, and in the Mississippi valley in lead, zinc, and copper; while salt and petroleum occur at several horizons in the palæozoic series in different parts of the great basin. The western or Rocky mountain region is the great source of the precious metals, the deposits of which, as has been observed, may be described in a general way as arranged in parallel zones coinciding with the mountain belts. Along the Pacific Coast range are deposits of quicksilver, tin, and chrome, while the belt of the Sierra Nevada and the Cascades carries a range of copper mines near its base, and a line of gold-bearing veins and gold alluvium on its western flank. Along the E. slope of the Sierra lies a zone of silver mines stretching into Mexico, and including the great Comstock lode of Nevada, while silver ores abound in the subordinate ranges between the Sierra and the Wahsatch. The silver-lead ores of New Mexico, Utah, and western Montana, and the still more eastern gold deposits of New Mexico, Colorado, Wyoming, and Montana, follow the same general distribution. (For particulars of the mineral deposits of the United States, see ANTHRACITE, BORAX, COAL, COPPER MINES, GYPSUM, IRON ORE, MARBLE, PETROLEUM, SALT, and the articles on the different metals and states.)—The republic abounds in natural curiosities and other objects of interest. Immense numbers of persons annually resort to the mineral springs, the most prominent of which are mentioned in the article MINERAL SPRINGS. The White mountains and other portions of the Appalachian chain are noted for their striking or picturesque scenery; while the great mountain ranges of the Pacific slope present innumerable scenes of unsurpassed beauty and sublimity, among which are the "parks" and lofty peaks of Colorado, the Yellowstone national park in Wyoming, and the Yosemite valley in California. The prairies and arid plains are noteworthy features. Besides the great cataract of Niagara and the Yosemite falls, the falls of the Missouri in Montana, St. Anthony's falls of the Mississippi in Minnesota, and the falls of the Snake river in Idaho may be instanced. The most remarkable caves are the Mammoth cave in Kentucky; Madison's cave and Weyer's cave, Virginia; Nicojack cave, Georgia; and Fountain cave, near St. Paul, Minnesota. Not the least interesting among the picturesque features of the country are the remarkable channels cut by some of the rivers through ranges of hills or rocky ridges. Such are the passage of the Hudson through the Highlands of New York; the Delaware Water Gap; the passage of the Potomac through the Blue Ridge at Harper's Ferry; the "gates of the Rocky mountains" on the upper course of the Missouri in Montana; the deep cañons of the Colorado of the West; and the "cascades" where the Columbia river breaks through the Cascade range on the boundary between Washington territory and Oregon. The natural bridge of Virginia, the pictured rocks on the shore of Lake Superior in Michigan, the mammoth trees of California, the geysers, and the popular seaside resorts, as well as nearly all the scenes above mentioned, are described in other articles.—The climate of the United States is as varied as might be expected in a country stretching through 25 degrees of latitude, and rising from low swampy shores to vast elevated and arid table lands and prodigious mountain ranges. Except in the extreme south and on the Pacific coast, it is characterized by fickleness and by great difference in temperature between summer and winter. Transitions from heat to cold and from cold to heat, to the extent of 30° in a few hours, are common at all seasons, and the alternations from rain to drought are nearly as remarkable. The summer is marked by intense heat, the thermometer rising sometimes several degrees above 100° F. In the north this extreme is seldom continued for more than a few days at a time, and in the southern states the heat, though long continued, is seldom so great. In winter the thermometer often falls below zero in the north, and it has been known, particularly in Minnesota and Dakota, to reach the freezing point of mercury (—40°). The Atlantic states have in general a temperature about 10° more severe than countries of the same latitude in western Europe, while California has a climate as mild as that of Italy. The northeastern states are subject to chill winds from the Atlantic (and at points along the coast to fogs), especially in the spring months; and the ice fields of British North America are the cradle of cold blasts which, having no mountain barrier to overcome, sweep over the northern states upon every considerable rise in the temperature further south. The great lakes mitigate to some extent the temperature of the country surrounding them, and other local features, such as the elevated plains and lofty ranges of the Rocky mountain system, affect the climate of particular parts of the country. The average annual temperature varies from 76° in S. Florida to 36° in N. E. Minnesota. The isothermal lines are irregular, but between the Pacific and the upper Mississippi they have a general tendency toward the north. On the Pacific coast the annual temperature of 52° in lat. 48° corresponds to a like temperature on the Atlantic coast in lat. 41.° Rain is abundant over the greater part of the republic, and pretty equally distributed throughout the year. In the north Atlantic states the fall is more regular than in the coast states S. of Washington, being in the latter more plentiful than in the former, and more frequent in summer than in winter. On the Pacific coast the rains are periodical, occurring chiefly in winter and spring, and S. of lat. 40° in autumn also. In the northern states snow frequently falls to a considerable depth, and in the most northerly portions it does not melt until spring. It is comparatively rare S. of the Potomac and on the Pacific coast, and when it does occur in these districts it lasts but a short time. The average annual precipitation of rain and melted snow on the Atlantic coast and on the gulf as far W. as the Sabine river varies from 36 to 60 inches, being generally from 40 to 50 inches; in the greater part of Texas and in the Mississippi valley it is from 24 to 50 inches, diminishing toward the north and west. The greatest precipitation occurs in Oregon and Washington territory, between the Coast mountains and the Pacific, varying from 80 inches in the N. part of the latter to 68 in the former. Between the Coast and Cascade mountains it is from 24 to 44 inches, and in N. California from 20 to 36, diminishing in the S. portion of that state. In the region bounded W. by the Cascade and Sierra Nevada mountains and E. by an irregular line commencing at the 95th meridian in N. Minnesota, and intersecting the 101st meridian in N. W. Texas, it does not exceed 20 inches, and is generally much less than that. Very little of this fall occurs in summer, and irrigation is a necessary adjunct to agriculture. In the mountains of this region snow falls to a great depth in winter. —The most fatal diseases of the New England and middle states are affections of the lungs; of the southern states, bilious fevers, with occasional severe visitations of yellow fever along the gulf; and of the western states, intermittent and bilious fevers and dysentery. The fever and ague so prevalent in the west is attributed to the miasmatic exhalations incident to the breaking up of new lands, and rapidly disappears as the country becomes settled. The cholera has generally been more fatal in the valley of the Mississippi than in any other part of the country.—The soil presents almost every variety, from the dry sterile plains in the region of the Great Salt lake to the rich alluviums of the Mississippi valley. It can most conveniently be described by following the seven great divisions indicated by the river systems of the country, viz.: the St. Lawrence basin, the Atlantic slope, the Mississippi valley, the Texas slope, the Pacific slope, the inland basin of Utah, commonly called the Great Basin, and the basin of the Red river of the North. 1. The St. Lawrence basin embraces parts of Vermont, New York, Pennsylvania, Ohio, Indiana, Illinois, Wisconsin, and Minnesota, and all of Michigan; it is an elevated and fertile plain, generally well wooded. 2. The Atlantic slope includes all New England except a part of Vermont: all of New Jersey, Delaware, the District of Columbia, South Carolina, and Florida; and portions of New York, Pennsylvania, Maryland, Virginia, West Virginia, North Carolina, Georgia, Alabama, and Mississippi. It may be subdivided into two regions, a N. E. section and a S. W. section, separated by the Hudson river. The former is hilly, and generally better adapted to grazing than tillage, though some parts of it are naturally fertile, and a large proportion is carefully cultivated. The S. W. section may be again divided into a coast belt from 30 to 150 m. in width, running from Long Island sound to the mouth of the Mississippi, and including the whole peninsula of Florida; and an inland slope from the mountains toward this coast belt. The former as far S. as the Roanoke river is sandy and not naturally fertile, though capable of being made highly productive; from the Roanoke to the Mississippi it is generally swampy, with sandy tracts here and there, and a considerable proportion of rich alluvial soil. The inland slope is one of the finest districts in the United States, the soil consisting for the most part of alluvium from the mountains and the decomposed primitive rocks which underlie the surface. 3. The Mississippi valley occupies more than two fifths of the area of the republic, and extends from the Alleghany to the Rocky mountains, and from the gulf of Mexico to British North America, thus including parts of New York, Pennsylvania, Maryland, Virginia, West Virginia, North Carolina, Georgia, Alabama, Mississippi, Louisiana, Texas, New Mexico, Colorado, Wyoming, Montana, Dakota, Ohio, Indiana, Illinois, Wisconsin, and Minnesota, and all of Kentucky, Tennessee, Arkansas, Indian territory, Missouri, Iowa, Nebraska, and Kansas. It is for the most part a prairie country, of fertility unsurpassed by any region on the globe, except perhaps the valley of the Amazon. The ground in many places is covered with mould to the depth of several feet, in some instances 25 ft. But the N. W. part of the valley offers a strong contrast to the remainder. There is a plateau from 200 to 400 m. wide lying at the base of the Rocky mountains, part of it incapable of cultivation on account of the deficiency of rain and lack of means of irrigation, and part naturally sterile. 4. The Texas slope includes the country S. W. of the Mississippi valley, drained by rivers which flow into the gulf of Mexico, and embracing nearly all of Texas and portions of Louisiana and New Mexico. (See Texas.) 5. The Pacific slope, embracing the greater part of California, Oregon, and Idaho, with Washington territory and Arizona, and parts of New Mexico, Utah, Colorado, Wyoming, and Montana, is generally sterile. That part however between the Coast range and the ocean, and the valleys between the Coast range and the Cascade range and Sierra Nevada are very fertile; and the same may be said of a few other valleys and mountain slopes, though these are commonly better adapted to pasturage than to agriculture. 6. The great inland basin of Utah, which besides Utah includes Nevada and parts of California, Oregon, and Idaho, is probably the most desolate portion of the United States, though in parts the soil with irrigation yields good crops, and grazing may be more extensively pursued. It abounds in salt lakes. 7. That portion of the basin of the Red river of the North which belongs to the United States is confined to the small tract in the N. part of Dakota and Minnesota; it contains some very productive lands, especially in the river bottoms.—The varied physical aspects of the country indicate a correspondingly varied ve-

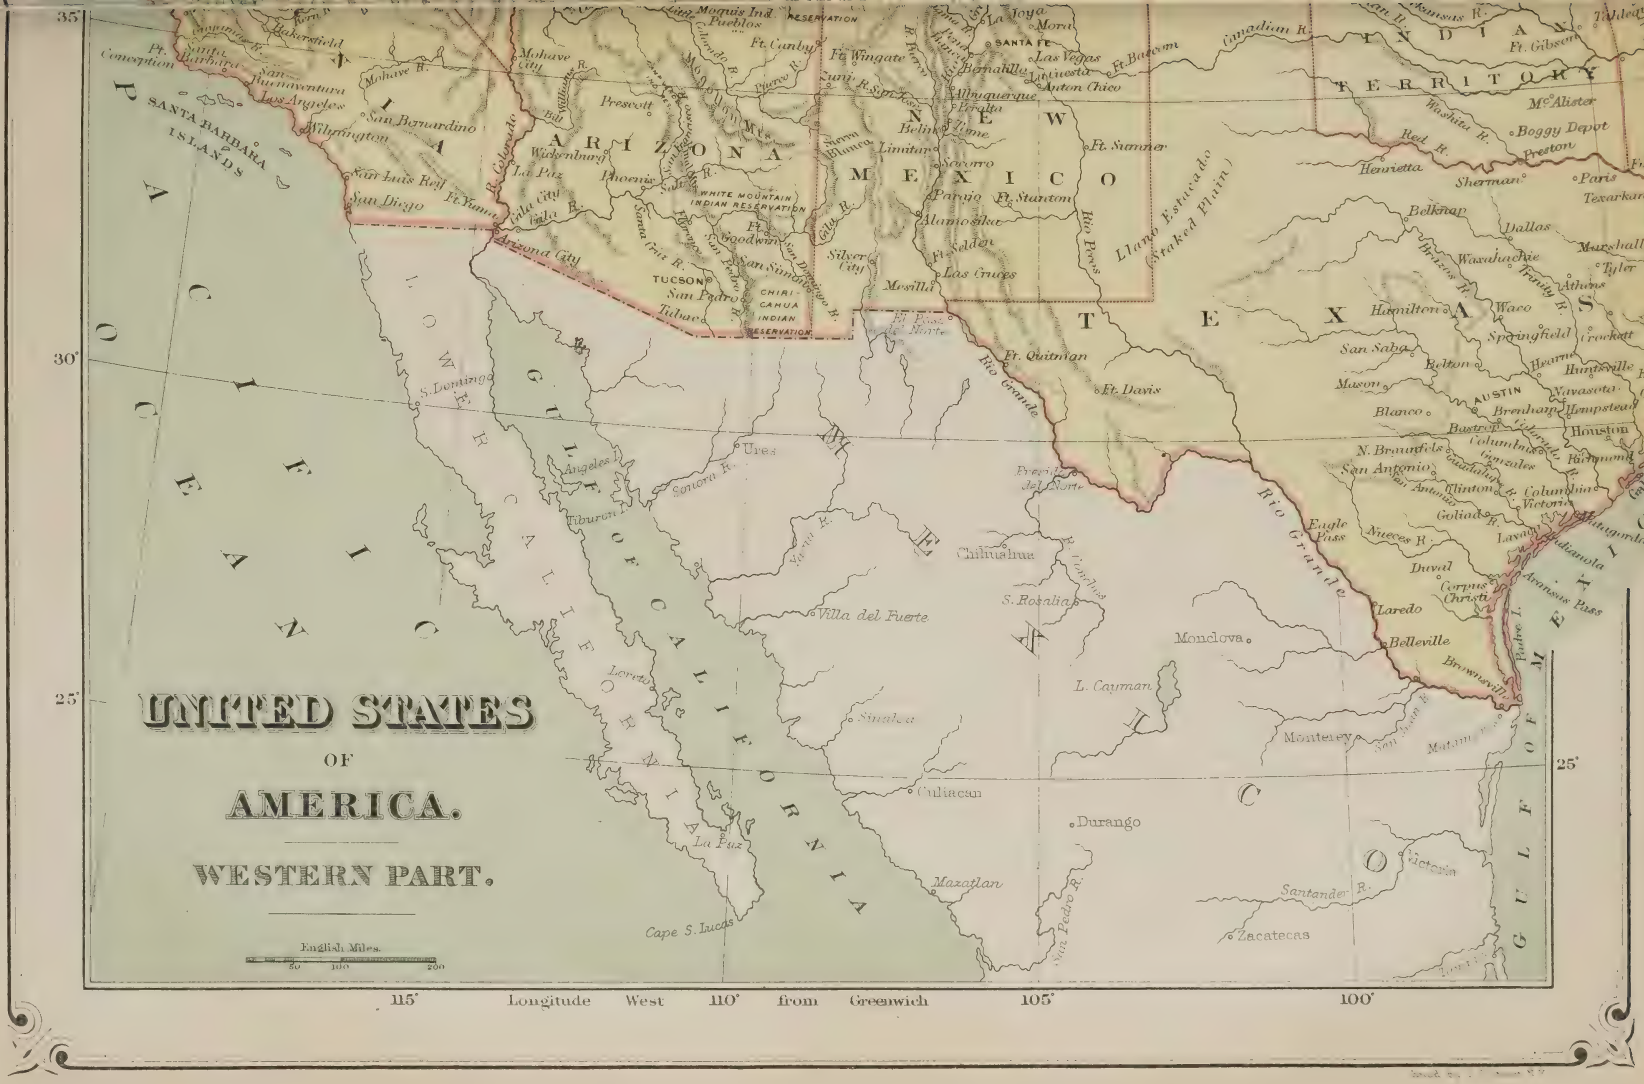
WESTERN PART.



getation, and an elaborate survey of its botanical features would require its subdivision into 20 or more regions characterized by the prevailing vegetable forms; but a mere glance at a few broad geographical divisions must suffice, noticing only the more conspicuous flowering plants. 1. The northern states, east of the Mississippi, from the northern border to Virginia and Kentucky, present a flora essentially European in its general aspects, though it is largely wanting in the alpine and subalpine plants so common in northern Europe. Our alpine or arctic flora (excepting that of Alaska) is confined to the limited areas presented by the tops of the higher mountains of New England and New York; and of the little over 30 species found on these, only 4 are peculiarly American. The trees of this division are largely of European genera; the pine, spruce, birch, oak, maple, ash, elm, and others, which make up the bulk of the forest growth, are also the prevailing genera of Europe, but they are mostly represented here by different species. The principal trees not of European genera are the magnolias, tulip tree, yellowwood, buckeye, locust, honey locust, liquidambar, tupelo, sassafras, and all the hickories; while among the conifers are the arbor vitæ and the hemlock spruce, which by some botanists is placed in a genus distinct from the spruces. Abundant shrubs of European genera are sumachs, thorns, azaleas, rhododendrons, dogwoods, whortleberries, blackberries, &c.; while the laurel (*Kalmia*), papaw (*asimina*), prickly ash, witch hazel, spice bush, leatherwood, buffalo berry, and others, are peculiarly American. As in most floras, the *compositæ* are here very numerous, one eighth of all the species belonging to this family; some of these, as the solidagos, asters, sunflowers, and others, are so abundant as to give a warm coloring to the autumn landscape. Two or three cacti and one pitcher plant, and the mistletoe, genera very abundant in other regions, are found here. A remarkable analogy has been noticed between the flora of the eastern coast of this continent and corresponding portions of eastern Asia, many of the genera of this region being found elsewhere only in Japan, China, and the Himalayas. The flora of this division gradually blends with that of the next. 2. The southern states, from the preceding to the gulf of Mexico, exclusive of southern Florida. Along the mountains northern plants extend far southward. Among southern species of northern genera of trees, the most conspicuous are the great magnolia (*M. grandiflora*), one of the finest of evergreen trees, the live oak, so valued for timber, and the old-field and long-leaved pines; the pecan, really a hickory, abounds here, and the planer tree, hackberry, persimmon, and holly, not common at the north, have here their centres of greatest abundance; the deciduous or bald cypress, barely a native of the northern region, is here abundant and valuable. Among the trees of genera not found in the northern division are Osage orange, catalpa, wild China, sorrel tree, Georgia bark, devilwood, and alligator pear. Torreya is a very local conifer; and of the four palms, the cabbage palmetto may be ranked as a tree; a grass, the giant cane, often reaches 20 to 30 ft., and forms dense jungles known as canebrakes. The herbaceous plants present great attractions to the botanist, and some from their contrast with northern forms arrest the attention of the unbotanical traveller. Long or Spanish moss is a true epiphyte, and hangs from the trees in such abundance as to form a feature in the scenery; and other tillandsias, several ferns, and two orchids are other epiphytes to be met with in the far south. This region is the home of the pitcher plants (*Sarracenia*), and of the very local Venus's fly trap (*Dionæa*), the most wonderful of all carnivorous plants. The bright colors of the coral plant, several species of hibiscus, the Carolina pink (*Spigelia*), the abundance of phloxes, gerardias, and convolvuluses, and the fragrance of the Carolina jasmine (*gelsemium*), remind the northerner that he is surrounded by a new flora. 3. Southern Florida, especially the "keys," presents very distinct features, the trees particularly being those characteristic of the West Indies. Conspicuous among these are the mangrove (also found elsewhere along the gulf), the mahogany and lignum vitæ trees, the poisonous manchineel, several small-fruited figs, the tropical papaw (*Carica*), calabash, and many others. In the Florida arrowroot or coontie (*zamia*) is found our only representative of the cycads. The orange grows here as a naturalized plant in such abundance that many regard it as a native. 4. The plains west of the Mississippi, and the Rocky mountains. Immediately west of the Mississippi the flora is not widely different from that on the eastern side; but as the wide plains and the elevated dry plateaus are reached, a different vegetation appears, while that of the Rocky mountains is mainly unlike that of the high eastern peaks; some wide districts have the soil so strongly impregnated with alkali that few plants can exist. The plains are mostly destitute of trees, except along the courses of the streams, where the cottonwoods (species of poplar) are most abundant. Here are found wide areas of single or few species; on the more fertile portions the buffalo grass covers vast tracts, multiplying so freely by its spreading stems that it rarely produces seed. On the sterile portions the "everlasting sage brush" (*Artemisia tridentata*) gives a sombre hue as far as the eye can reach; the "greasewood" of the travellers (*sarcobatus*) and other chenopods are often abundant; plants of this family, with a few composites, grasses, and sedges, make up the flora of the wide alkaline stretches. On the more fertile plains the leguminous plants, and those of the phlox and evening primrose families, are frequent. The mountains afford a rich and varied flora; here are found a great variety of pines, spruces, and firs, and above them a truly alpine region, which has enriched our flora with a long list of choice species. 5. The Pacific coast, with the neighboring mountain ranges, within the influence of the mild atmosphere of the ocean, has a wonderfully varied flora. Among trees, maples, buckeye, cherry, buttonwood, oaks in great number, chestnut, birches, willows, and others of genera common to the northern states of the east, are here represented by species peculiar to the coast. The conifers of this region are among the loftiest; and pines, spruces, firs, cypresses, and arborvitæs make up an arboreal vegetation of great variety and interest. Among the trees of genera not found in the other divisions are the madroña, sometimes called strawberry tree, a magnificent broad-leaved evergreen (*arbutus Menziesii*), and the California laurel or bay (*oreodaphne*). The genus *Torreya*, of which there is a species in Florida, is represented here by the "nutmeg tree;" California white cedar, sometimes reaching 140 ft., is a *libocedrus;* here is the home of the sequoias or redwoods, of which *S. gigantea*, widely known as the mammoth tree, towering from 300 to 450 ft., is one of the two largest trees of the world. The shrubby growth of this region presents numerous species of eastern genera, and is equally varied. Among herbaceous plants, the range from the coast to the mountain tops is wide, and presents a flora so rich that the labors of botanists have not yet exhausted it. Many of the choice ornaments of our gardens, eschscholtzias, gilias, nemophilas, the mimulus, whitlavia, collomia, lupines, pentstemons, and others, have here their homes; perhaps the most interesting plant of this region is the *Darlingtonia*, a pitcher plant of curious structure, and, like its eastern relatives the sarracenias, carnivorous. A marked feature of the flora of this region is the wide areas occupied by single species, almost to the exclusion of all others. A great many interesting native grasses are found here. 6. Western Texas, 200 m. from the coast, is a high plateau, and with the lower parts of New Mexico and Arizona forms a region the vegetation of which is more like that of Mexico than of any other part of the United States; it is a region of elevated table lands, cut up by sterile mountain ranges, with but few streams and very little rain. Along the watercourses are found cottonwoods and willows, but the majority of the few trees which occur elsewhere are of the *leguminosæ*, the most frequent being the mezquite and the related screw bean; these and the *tesota* or ironwood (*Olneya*), *palo verde* or green tree (*cercidium* and *Parkinsonia*), cassias, and others, the Mexican pistachio, Spanish buckeye (*Ungnadia*), mulberry, and a few others, make up the tree growth, except in the mountains, where in favorable localities pines, oaks, &c., occur. The shrubs are numerous, and, in common with other vegetation, abundantly armed with prickles and spines; some shrubs, such as *Kœberlinia* and *holocantha*, rarely show any leaves, the green bark answering their purpose, but have every branch and twig sharpened to form a formidable spine, and the leafy shrubs often have their branches thus terminated, or are furnished with special thorns; a thick growth of these spinescent shrubs is known as "chaparral," and forms an impenetrable barrier to man and beast. In this division are found agaves, dasylirions, and yuccas, some reaching the stature of a tree. The most characteristic plants of a large part of this region are the cacti, which occur in a great number of species presenting a wide variety of forms and size. Opuntias of the prickly pear style are numerous; some are 6 ft. high, others with cylindrical stems are scarcely bigger than a quill, while the tree-like *O. arborescens* is as large as an apple tree. Species of the globular mammillarias are not larger than a walnut, while some of the oblong echinocacti are of the size of a barrel; all these are dwarfed by the giant cereus, the candelabra-like stems of which sometimes reach 40 or 50 ft. In some localities almost the whole vegetation is made up of these plants, which present nature in her most grotesque aspect.—Flowerless or cryptogamous plants, especially those of a lower organization, are much less restricted in their distribution than flowering plants. Among the higher orders of these, the ferns and club mosses, many of the genera and also of the species are the same as those of Europe, and in the mosses, lichens, and lower forms the number of European species is still greater; but all these families present a large number of peculiarly American genera, and American species of European genera. Among ferns, the most noticeable of the northern and southern states are the maiden-hair (*adiantum*), the walking fern (*camptosorus*), the climbing fern (*lygodium*), the golden fern (*polypodium aureum*), and the so-called sensitive fern (*onoclea*). The smallest of our ferns is *schizæa*, very local in New Jersey, and one of the most striking is *vittaria*, an epiphyte in Florida, the fronds of which are more like a tuft of grass than a fern. The Pacific coast, the Rocky mountains, and even the desert region of Arizona, have their peculiar species. In mosses and hepaticas the country is very rich, and in these as well as in lichens the few botanists who devote themselves to their special study are continually adding to the number of known species. The fungi, though but partially investigated, are numerous, with a large number of edible species among them. In algæ the Atlantic coast, while it has many that are common to the shores of Europe, produces its peculiar species of interest; but owing to the sandy character of a great portion of the shores, the marine vegetation is as a whole very meagre. The keys of Florida are rich in species, many of which, as well as those of the gulf of Mexico, are also common to the Mediterranean. On the Pacific coast are found the gigantic *macrocystis*, with stems several hundred feet long, and other gigantic algæ, which make fields so dense and extended that navigators carefully avoid them. The partial study that our fresh-water algæ have received shows that this obscure vegetation is rich in interesting forms.—A marked feature of the vegetation of a large portion of our territory is the introduced plants, which are not only numerous as species, but as individuals; the climate being especially favorable to their development, many foreign plants appear to thrive better here than at home. The great majority of the agricultural weeds are of exotic origin; in some of the older states the meadows are white with oxeye daisy or yellow with foreign buttercups, while in Virginia they are blue with viper's bugloss (*echium*); the thistles, docks, purslane, crab grasses, and other pests of the farmer and gardener, are natives of other countries, as are also the stramoniums, hemlock, and other occupants of waste places around settlements. Many natural meadows are due to foreign grasses, and white clover is so generally introduced that farmers in the eastern states seldom sow it, being quite sure that, with a favorable soil, it will "come in." Two plants in the southern states afford remarkable instances of rapid naturalization. A few years ago a little prostrate composite (*acanthospermum*) appeared in the waste places, especially along the railroads, suddenly and completely carpeting the ground; it is a South American plant, the seeds of which were probably introduced with wool. The other is a little leguminous plant called Japan clover (*lespedeza striata*), which at the close of the civil war appeared all over the southern states. As cattle eat it, the introduction cannot be regarded as a misfortune; but this wide and sudden distribution of a Japanese species still remains a puzzle. Upon the Pacific coast, the most prominent introduced plants are mostly valuable ones; the wild oat (*avena fatua*), which covers such wide ranges to the exclusion of all other vegetation, is a European species; and bur clover (*medicago*) and alfilaria (*erodium*), which in certain seasons are the main reliance of stock growers, are both weeds introduced by the early Spanish settlers.—The zoölogy of the United States is essentially that of North America, nearly every species found on the North American continent having its habitat in some part of the states or territories. The *quadrumana*, embracing the entire monkey tribe and its congeners, are wanting. Of the *cheiroptera*, or bat tribe, there are 3 genera and 11 species (outside of Alaska, the fauna of which is not included in this description). Of the *carnivora*, the largest is the couguar or catamount, a formidable animal, inferior in strength and ferocity to the South American jaguar. There are 6 or 7 species of the fox. Of wolves there are the gray wolf of the wooded districts, of which there are several varieties, and the prairie wolf, the American representative of the jackal. To the *digitigrada* also belong the pine marten or American sable, the fisher, mink, weasel, skunk, and ermine. Among the *plantigrada* we have the black bear, the grisly bear, the largest and most formidable of American carnivora, and the California bear. The remaining members of the order found here are the badger, the wolverene or glutton, and the raccoon. Of the *pinnigrada*, the common seal occurs on the Atlantic coast, and the northern sea bear (*callorhinus ursinus*), which is taken in great numbers on the Pribyloff islands belonging to Alaska, occurs as far south as the mouth of the Columbia. The *ruminantia* are represented in considerable numbers. Among the *cervidæ* or deer family we have the moose and caribou, now confined to the N. E. states, and very scarce even there; the wapiti, incorrectly called the elk; and 5 or 6 species of deer. There is an antelope, the prong-horn, a native of the Rocky mountain region; and a representative of the sheep family, the bighorn or Rocky mountain sheep, found in the region of the Rocky mountains and Sierra Nevada. The bison, usually called the buffalo, is the only wild representative of the ox family. Of the amphibious mammals, a species of the manatee or sea cow frequents the shores of Florida and the gulf of Mexico. The porpoise and 5 or 6 species of the dolphin, among them the white whale, and the narwhal, are found along the coast; and the smaller species of whale are not uncommon, while the great sperm whale appears at some distance from the Pacific coast. The *insectivora* are represented by the mole, 3 genera and 7 or 8 species, and by 12 species of shrew. Among the *rodentia* are the beaver, porcupine, 10 or 12 squirrels proper, several flying squirrels, 4 or 5 prairie squirrels, 2 prairie dogs, and the gopher or pouched rat, of which there are several species; the woodchuck or American marmot; the muskrat; the rat tribe, of which 2 genera and 3 or more species are indigenous; the mouse tribe, of which there are 4 genera and about 20 species; the meadow mouse, of numerous species; the hare, of which there are 4 or 5; and the rabbit, of which there are at least 6 species. The *marsupialia* are represented by a single genus, the opossum. Of birds the genera and species are so numerous, that only the more prominent can be named. Of the order *raptores* (birds of prey), the eagle, of which 5 species have been ascertained to exist in the United States, takes the first place. Next follow the vultures, of which at least half a dozen species inhabit the United States, from the king vulture of California to the turkey buzzard and carrion crow; the hawks, of which there are not less than 25 ar 30 species, including the falcon, kite, hen hawk, goshawk, sparrow hawk, &c.; and the owls, of which there are at least 40 species. The *scansores* or climbers are represented by the Carolina parrot and the woodpeckers, a well known genus, of which there are many species. The order *insessores* is very numerous in the United States, and includes the song birds as well as those distinguished by their cry or sharp shrill note. The most common members of the order are the thrush tribe, including the bird here called robin, the mocking bird, and the cat bird; the warblers and flycatchers; the swallows, a numerous family; the finch tribe, which includes the sparrows; the kingfishers, the crow tribe, the orioles, the grakles, and the humming birds. The *rasores*, divided into the suborders *columbæ* and *gallinæ*, are numerously represented. Pigeons and doves of many species are found in vast numbers in the wooded portions of the western and northwestern states, and are not uncommon in any part of the Union. There are no true partridges in the United States, the partridge of the northern states being a grouse, and that of the southern states a quail; but the grouse, of at least a dozen species, quail, wild turkey, and several other species of gallinaceous birds, occur in great numbers. Of the *grallatores* or waders we have the flamingo, several herons, the ibis, the crane, the coot or mud hen, the rail, sandpiper, snipe, plover, &c. The *natatores* or swimmers are here a very numerous order. Of the *anserinæ* or geese there are about 20 species, including 2 species of swans; and of the *anatidæ* or duck family, at least 30. There are also 2 species of pelicans, a great number of species of gulls, and half a dozen cormorants. In reptiles the United States are less prolific than some other countries. There is a considerable variety of tortoises, though few of great size; and the keys or small coral islets along the coast of Florida, and the sandy spits along the shores of the southern Atlantic and gulf states, are frequented by the green and other sea turtles in great numbers. The alligator inhabits the rivers and bayous of the gulf states. The saurians are abundant, especially in the southern states, and include a great variety of lizards, skinks, horned frogs, monitors, &c. The ophidians or serpents are numerous, but only the rattlesnakes, the moccason snakes, and the vipers are venomous. The black snake is the only large constrictor in the United States. The batrachians embrace numerous species of frogs, tree frogs, 2 or 3 species of toad, the menobranchus, siren, 3 or 4 tritons or newts, and about 20 species of salamander. The number of genera and species of fish visiting or inhabiting the waters of the United States is too great to be enumerated. The most remarkable of the spine-finned are the perch, mackerel, sword fish, and mullet. Among those with soft abdominal fins, the best known are the salmon, shad, menhaden, alewife, herring, pike, and carp; of those with soft fins at the throat, cod, flounders, flat fish, &c.; and of fish without ventral fins, several species of eels, both fresh and salt water fish, and the lamprey. The shark, of which there are 16 or 18 species, and the ray or skate, of which there are 30 or 40, are the most formidable on the American coasts. Other fish well known and highly prized for the table are the halibut, tautog, blue fish, sea and striped bass, tomcod, porgy, perch, roach, dace, brook trout, lake trout, giant pike or muscalonge, and the delicious white fish of the lakes. Of mollusks, the *acephala* are widely distributed on the sea coast and through the lakes and rivers. The oyster of numerous varieties attains a flavor and excellence unknown elsewhere. The pearl oyster has been found on the California coast, and several of the *unionidæ* secrete pearls of considerable value. The soft-shelled clam (*mya arenaria*) and the quahaug or round clam (*Venus mercenaria*) are also much prized in some districts as articles of food. The pecten or scollop and the mussel are also edible species of bivalves. Others of the order are the cockle, hammer shell, razor shell, club shell, waterpot shell, and *teredo* or ship worm; and in the rivers the numerous species of *unio* and *anodonta*, usually called fresh-water clams, are abundant. There are many genera and species of land snails and slugs, and many species of fresh-water and marine *gasteropoda;* and the Atlantic, Pacific, and gulf of Mexico wash upon our shores great numbers of the cephalopods which inhabit their waters, among them the squid. The *crustacea* are numerous, and many of them edible. Crabs, lobsters, shrimps, horseshoes or king crabs, &c., abound on the coast; and the crawfish and land crab are found in the interior. Of the *arachnida* there are in the gulf states some venomous species, as the scorpion and several species of spider; but for the most part the spiders, mites, &c., of the United States are harmless. The centipede, though properly belonging to the tropics, is occasionally found in the southwestern states. The insect tribes are too numerous to receive more than a passing notice. The beetles are very abundant, and include many genera. There are several species of locust, some of them as destructive to vegetation as the locust of oriental countries. The bee, wasp, hornet, and humblebee, each of numerous species; the vast tribe of butterflies; the whole family of flies, including a blistering fly nearly equal to the Spanish; and the other insect orders, all have their representatives; and as we approach the tropics their number and variety greatly increase.—The population of the country prior to the first census, according to Bancroft, was as follows:

YEARS.	White.	Colored.	Total.
1688	....	......	200,000
1714	375,750	58.850	434.600
1727	502,000	78.000	580,000
1750	1,040,000	220,000	1,260,000
1754	1,165,000	260,000	1,425,000
1760	1,385,000	310,000	1,695,000
1770	1,850,000	462,000	2,312,000
1774	2,100,000	500,000	2,600,000
1780	2,383,000	562,000	2,945,000

The population as reported by the decennial censuses has been as follows:

YEARS.	White.	Colored.	Free colored.	Slave.	Aggregate.
1790....	3,172,006	757,208	59,527	697,681	3,929,214
1800....	4,306,446	1,002,037	108,435	893,602	5,308,483
1810....	5,862,073	1,377,808	186,446	1,191,362	7,239,881
1820....	7,862,166	1,771,656	233,634	1,538,022	9,633,822
1830....	10,537,378	2,328,642	319,599	2,009,043	12,866,020
1840....	14,195,805	2,873,648	386,293	2,487,355	17,069,453
1850....	19,553,068	3,638,808	434,495	3,204,313	23,191,876
1860....	26,922,537	4,441,830	488,070	3,953,760	31,443,321
1870....	33,589,377	4,880,009	4,880,009	....	38,558,371

Included in the aggregate for 1860 were 44,021 Indians and 34,993 Chinese, and in that for 1870, 25,731 Indians out of tribal relations, 63,199 Chinese, and 55 Japanese. The number of Indians sustaining tribal relations in 1870 was estimated at 357,981. In 1875 the number was reported by the commissioner of Indian affairs at 279,337, exclusive of 11,650 in Alaska; land reserved for Indians, 165,729,714 acres; number of agencies, 82. The representative population, excluding Indians not taxed and the inhabitants of the territories, was 38,115,641. The average increase in the aggregate population since 1870, in the 14 states that took censuses in 1875 and one in 1874, was over 15½ per cent.; at the same rate the population of the United States in 1875 would be about 44,590,000. The density of population in 1870 was 10·7 persons to the square mile, or, excluding the territories, 19·21. The total number of families in the United States was 7,579,363, having an average of 5·09 persons to each; the number of dwellings was 7,042,833, with an average of 5·47 persons to each. Of the total population in 1870, 32,991,142 were born in the United States and 5,567,229 in foreign countries. The number born of foreign parents was 9,734,845, and there were 1,157,170 persons of mixed (half native and half foreign) parentage, making 10,892,015 persons having one or both parents foreign. Only the nativity of those born in foreign countries is reported by the census. The distribution of the entire foreign element (10,892,015) into the chief nationalities has been computed as follows: Irish, 3,630,839; German, 3,307,205; British, 1,496,739; Scandinavian, 467,183; all others, 1,990,049. (See EMIGRATION.) The distribution of population by sex, nativity, and color, in 1860 and 1870, was as follows:

Male citizens 21 years of age and upward..................	8,425,941	....	....

The total population 10 years of age and over was 28,228,945, of whom 14,258,866 were males and 13,970,079 females. There were engaged in all occupations 12,505,923, of whom 10,669,635 were males and 1,836,288 females, and 739,164 were from 10 to 15 years of age; in agriculture, 5,922,471 (5,525,503 males and 396,968 females), including 2,885,996 laborers and 2,977,711 farmers and planters; in professional and personal services, 2,684,793 (1,618,121 males and 1,066,672 females), including 2,053 actors, 43,874 clergymen, 975,734 domestic servants, 5,286 journalists, 1,031,666 laborers not specified, 40,736 lawyers, 62,383 physicians and surgeons, and 126,822 teachers not specified; in trade and transportation, 1,191,238 (1,172,540 males and 18,698 females); and in manufactures and mechanical and mining industries, 2,707,421 (2,353,471 males and 353,950 females), including, besides 41,619 mill and factory operatives not specified, 111,606 cotton and 58,836 woollen mill operatives, and 152,107 miners. The total number of blind was 20,320; deaf and dumb, 16,205; insane, 37,432; idiotic, 24,527. The total deaths from all causes during the year ended May 31, 1870, as reported by the census, were 492,263, being

---

* Including civilized Indians.

1·28 per cent. of the entire population, excluding the territories. The highest rates of mortality were 2 per cent. in Louisiana and 1·77 in Massachusetts; lowest, 0·69 in Oregon, 0·80 in Minnesota, and 0·81 in Iowa. The total number of births during the year, and living on May 31, was 1,100,475. Of the total number of deaths, 188,684 were from general diseases, of which 94,832 were chiefly acute and 93,852 chiefly chronic. Under general diseases are classed those affections which involve a great number of diverse organs, or the whole frame, rather than any special part of it, the most important being fevers and consumption. Under local diseases were classed 60,455 deaths from those of the nervous, 17,034 of the circulatory, 63,971 of the respiratory, and 73,999 of the digestive system, 4,744 of the urinary system and male organs of generation, and 1,318 of the female organs of generation; 4,810 from affections connected with pregnancy; 2,187 from diseases of the organs of locomotion, and 2,778 of the integumentary system. Besides these, there were 28,493 deaths from conditions not necessarily associated with general or local diseases, 2,351 from poisons, 1,069 from worms, 364 from malformations, 22,740 from accidents and injuries, and 17,266 from unknown causes. The number of deaths from certain principal diseases, with their ratio to the total number from all causes, was as follows:

DISEASES.	Number of deaths.	Deaths from all causes to one from disease specified.
Cholera infantum	20,255	24·3
Consumption	69,896	7·0
Croup	10,692	46·0
Whooping cough	9,008	54·6
Measles	9,237	53·3
Pneumonia	40,012	12·3
Smallpox	4.507	109·2
Diphtheria	6,303	18·5
Scarlet fever	20.320	
Intermittent fever	7,142	43·1
Remittent fever	4,281	
Cancer	6,224	79·1
Cerebro-spinal fever	651	20·0
Enteric fever	22,187	
Typhus fever	1,170	
Diarrhœa	14,195	15·8
Dysentery	7,912	
Enteritis	9,046	

The highest death rate for consumption was in the New England states; the lowest in the southern and western states, and especially the territories. Intermittent and remittent fevers were most destructive in the southern states, and least in New England.—The agricultural resources of the United States, though but partially developed, contribute largely to its wealth and political importance. Of the 12,505,923 persons engaged in all occupations in 1870, 5,922,471 were employed in agriculture, including 2,977,711 farmers and planters and 2,885,996 laborers. The exports of agricultural produce form the most important feature of the commerce of the country; in 1874 they amounted to more than $700,000,000 in value. The exports of breadstuffs were valued at $161,198,864, including wheat worth $101,421,459, wheat flour $29,258,094, and Indian corn $24,769,951; of provisions, $78,328,990, including bacon and hams valued at $33,383,908, cheese $11,898,995, preserved meats $19,308,019, and pork $5,808,712; of cotton, $211,223,580; and of leaf tobacco, $30,399,181. The following are the most important statistics of agriculture, as reported by the censuses of 1860 and 1870:

PARTICULARS.	1860.	1870.
Land in farms, acres	407,212,538	407,735,041
" " improved	163,110,720	188.921,099
" " woodland	244,101,818	159,310,177
" " other unimproved		59,503,765
Percentage of unimproved to total	59·9	53·7
Number of farms	2,044,077	2,659,985
Average size, acres	199	153
Cash value of farms	$6,645,045,007	$9,262,803,861
" " of farming implements and machinery	$246,118,141	$336,878,429
Total amount of wages paid during the year, including value of board	....	$310,286,285
Total estimated value of all farm productions, including betterments and additions to stock	....	$2.447,538.658
Produce of orchards, value	$19,991,885	$47,335,189
" of market gardens	$16,159,498	$20,719,229

Honey	23,366,357	14,702,815

The leading crops in 1874, as reported by the department of agriculture, were as follows:

PRODUCTS.	Number of bushels, &c.	Number of acres.	Value.	Average yield per acre.
Ind. corn, bush.	850,148,500	41,036,918	$550,043,080	20·7
Wheat........	309,102,700	24,967,027	291.107,895	12·3
Rye..........	14,990,900	1,116,716	12,870,411	13·4
Oats..........	240,369,000	10,897,412	125,047,530	22·0
Barley........	32,552,500	1,580,626	29,983,769	20·6
Buckwheat...	8,016,600	452,590	6,477,885	17·7
Potatoes......	105,981,000	1,310,041	71,823,330	80·9
Total.......	1,561,161.200	81,361,330	$1,087.353,900	......
Tobacco, lbs..	178,355,000	281,662	$23,362,765	632·2
Hay, tons.....	24,133,900	21,769,772	331,420,738	1·11
Cotton, bales..	3,800,000	....	256,215,000	......

The number and value of farm animals in 1874 were as follows:

ANIMALS.	Number.	Average price.	Value.
Horses.................	9,504.200	$68 01	$646,370,939
Mules	1,393,750	80 00	111,502,713
Milch cows.............	10,906,800	28 52	311,039,824
Oxen and other cattle...	16,313,400	18 68	304,858,859
Sheep..................	33,783,600	2 79	94,320,652
Swine..................	28,062,200	5 34	149,860,234

The states producing the most wheat in 1873 were: Iowa, 34,600,000 bushels; Illinois, 28,417,000; Minnesota, 28,056,000; Wisconsin, 26,322,000; California, 21,504,000; Indiana, 20,832,000; Ohio, 18,567,000; Pennsylvania, 15,548,000; Michigan, 14,214,000; Missouri, 11,927,000; Tennessee, 7,414,000; Kentucky, 7,225,000; New York, 7,047,000. Indian corn: Illinois, 143,634,000; Iowa, 105,200,000; Ohio, 88,422,000; Missouri, 70.846,000; Indiana, 67,840,000; Kentucky, 58,451,000. Oats: Illinois, 35,360,000; Pennsylvania, 31,229,000; New York, 27,548,000; Ohio, 23,090,000; Iowa, 21,130,000; Wisconsin, 18,862,000; Missouri, 15,670,000. Rye: Pennsylvania, 3,283,000; Illinois, 2,078,000; New York, 1,853,000; Wisconsin, 1,240,000; Kentucky, 1,107,000. Barley: California, 10,213,991; New York, 5,876,000; Iowa, 4,500,000; Illinois, 2,280,000; Ohio, 1,576,000; Wisconsin, 1,515,000; Minnesota, 1,060,000. Buckwheat: New York, 2,947,000; Pennsylvania, 2,022,000. Tobacco: Kentucky, 152,000,000 lbs.; Virginia, 50,000,000; Ohio, 32,500,000; Tennessee, 23,750,000; Maryland, 19,300,000; Missouri, 13,200,000. Wool (census of 1870): Ohio, 20,539,643 lbs.; California, 11,391,743; New York, 10,599,225; Michigan, 8,726,145; Pennsylvania, 6,561,722; Illinois, 5,739,249; Indiana, 5,029,023; Wisconsin, 4,090,670. The chief cotton-producing states are Mississippi, Georgia, Alabama, Louisiana, Texas, Arkansas, South Carolina, Tennessee, North Carolina, and Florida. In 1874 the greatest number of horses was in Illinois, of mules in Tennessee, of oxen and other cattle in Texas and Illinois, of milch cows in New York, and of hogs in Iowa and Illinois. The wool product of 1873 was estimated at 146,000,000 lbs. The industry of wool growing, though progressing but little east of the Mississippi, has been increasing from the Missouri to the Pacific coast. The states reporting the largest number of sheep in 1874 were California, 4,683,200; Ohio, 4,639,000; Michigan, 3,486,300; New York, 2,037,200; Iowa, 1,732,600; Indiana, 1,722,500; Pennsylvania, 1,674,000; Missouri, 1,408,500; Illinois, 1,408,200; Texas, 1,338,700; and Wisconsin, 1,187,600.—The growth of manufactures is shown by the following statistics, reported by the censuses of 1850, 1860, and 1870:

PARTICULARS.	1850.	1860.	1870.
Number of establishments............	123,025	140,433	252.148
Steam engines, number............	....	....	40.191
" " horse power............	....	....	1,215.711
Water wheels, number............	....	....	51,018
" " horse power............	....	....	1,130,431
Hands employed, all............	957,059	1,311,246	2,053,996
" " males above 16............	731,137*	1,040.349*	1,615.598
" " females above 15............	225,922†	270,897†	823,770
" " youth............	....	....	114,628
Capital............	$533,245,351	$1.009,855,715	$2,118,208,769
Wages............	$236,755,464	$378,878,966	$775,584.343
Value of materials............	$555,123,822	$1,031,605,092	$2,488,427,242
" of products............	$1,019,106,616	$1,885,861,676	$4,232,325,442

The difference between the schedules used in 1870 and those of 1860 and 1850 renders the above statements only approximately valuable for purposes of comparison. Certain industries are included in the results of 1870 which are excluded from those of 1860; others reported in 1860 do not appear in the above totals for 1870. The marked increase in the value of products between 1860 and 1870 is especially noticeable. Making allowance for the differences above referred to, and estimating the increase due to special administrative efforts in 1870 at $250,000,000, the superintendent of the census computes that the value of products in 1870 should be reduced to $3,924,958,660, in order to be fairly comparable with that of 1860. This would show an increase of $2,039,096,984, or 108·12 per cent., 56 per cent. of which is attributed to the general advance in prices, leaving 52 per cent. as the actual increase of manufacturing production. In 1870 the leading industries were:

* Total males. † Total females.

INDUSTRIES.	Number of establishments, 1870.	Hands employed, 1870.	Capital.	Wages.	Value of Materials.	Value of Products.
Agricultural implements	2,076	25,249	$34,834,600	$12,151,504	$21,473,925	$52,066,875

Taking the value of products as a standard, the leading manufacturing states were: New York, $785,194,651; Pennsylvania, $711,894,344; Massachusetts, $553,912,568; Ohio, $269,-

713,610; Missouri, $206,213,429; Illinois, $205,620,672; New Jersey, $169,237,732; Connecticut, $161,065,474; Michigan, $118,394,676; Rhode Island, $111,418,354; and Indiana, $108,617,278. The great centre for the manufacture of boots and shoes, straw goods, cotton and woollen goods, and textiles in general, is in Massachusetts. The manufacture of iron (excepting castings), machinery, cast-steel springs, and glass ware is most extensively carried on in Pennsylvania; of leather, flour, sewing machines, and refined molasses and sugar, in New York; of silk goods, in New Jersey; of agricultural implements, in Ohio; and of clocks, India-rubber and elastic goods, and hardware, in Connecticut. The following statement affords a comparison between the values of leading products in 1870 and 1860:

INDUSTRIES.	VALUE OF PRODUCTS.	
	1860.	1870.
Agricultural implements	$17,487,960	$52.066,875
Boots and shoes	91,889,298	181.644,090

The number of cotton (spinning) mills in the United States in 1875 was 875, having a total of 9,539,364 spindles; of these, 694 mills, with 9,057,543 spindles, were in northern, and 181 mills, with 481,821 spindles, in southern states. The quantity of cotton consumed during the year ending June 30 was 1,242,080 bales of 576,742,753 lbs., including 1,097,001 bales in northern and 145,079 in southern mills. The total number of spindles has increased from 7,114,000 in 1870 to 9,539,364 in 1875, the ratio of increase being larger in the southern than in the northern states. The consumption of cotton has increased from 930,736 bales in 1870 to 1,242,080 in 1875. For the production and manufacture of cotton in the United States, see Cotton, and Cotton Manufacture.—The statistics of mining in 1870 were as follows:

MINERALS.	No. of establishments.	Hands employed.	Amount of capital.	Value of products.
Asphaltum	1	23	$514,286	$450,000
Cinnabar	4	811	11,900,000	817,700
Coal, anthracite.	231	53,096	51,016,785	88,495,745
" bituminous	1,335	41,658	58,991,244	35,029,247
Copper	40	5,404	7,789,374	5,201,812
Gold, hydraulic mined	362	1,978	1,887,484	2,508,531
Gold, placer mined	1,632	8,463	5,624.549	7,266,613
Gold quartz	224	3,297	9,454,500	4.360,121
" and silver.	57	2.114	29,062,400	9,068,526
Iron ore	420	15.022	17,773,935	13,204,138
Lead	112	1,126	613,736	736,004
Marble	22	795	1,316,600	804,300
Nickel	1	48	60,000	24,000
Peat, cut	4	39	13,100	8.200
Petroleum	2,314	4.488	10,045.826	19,304,224
Silver quartz	102	1,056	4.015,000	3,248,861
Slate	101	1,749	2,738,239	1,311,492
Stone	997	12,573	7,152,854	9,971,100
Zinc	15	588	2,414,942	788,880
Total	7,974	154,328	$222,384,854	$152,598,994

Of the above named minerals, nearly one half in value were the product of Pennsylvania, which produced nearly all of the anthracite coal and of the petroleum, more than a third of the bituminous coal, and more than a fourth of the iron ore. The census returns of gold and silver were greatly below the actual production. The annual production of gold in the United States to 1873 and of silver to 1874 is given in the articles Gold, vol. viii., p. 81, and Silver, vol. xv., p. 57. The production of gold in 1874 amounted to about $42,000,000, and that of silver in 1875 to about $40,000,000. The production of pig iron in the United States has increased from 784,178 tons in 1855 to 919,770 in 1860, 931,582 in 1865, 1,865,000 in 1870, 2,854,558 in 1872, 2,868,278 in 1873, and 2,689,413 in 1874. About one fourth of the total amount is smelted from Lake Superior ores. The production of Bessemer steel has increased from 3,000 tons in 1867 to 40,000 in 1870 and 176,579 in 1874; that of other steel from 15,262 tons in 1865 to 35,000 in 1870 and 47,481 in 1874. In 1875 there were 10 establishments producing Bessemer and 42 other steel. The latest statistics of the production of iron and steel in the United States, as reported by the American iron and steel association, are as follows:

PRODUCTS—NET TONS.	1872.	1873.	1874.
Pig iron	2,854,558	2,868,278	2,689,413
All rolled iron, including nails	1,941,992	1,966,445	1,839,560
All rolled iron, including nails and excluding rails	941,992	1,076,368	1,110,147
Rails of all kinds	1,000,000	890,077	729,413
Bessemer steel rails	94.070	129,015	144,944
Iron and all other rails	905.930	761,062	584.469
Street rails	15,000	9,430	6.739
Kegs of cut nails and spikes	4,065,322	4,024,704	4,912,180
Merchantable Bessemer steel other than rails	16,430	27,985	31,635
Total of merchantable Bessemer steel	110,500	157,000	176,579
Crucible cast steel	27.260	32,786	34.128
Open-hearth steel	3.000	3.500	7,000
All other steel	7,740	13.714	6,853
Blooms from ore and pig iron	58,000	62,564	61,670

—The recent growth of the foreign commerce of the country is shown in the following statement of the gross specie value of imports and exports for years ending June 30:

To the total value of domestic exports in 1874 should be added $10,200,059 gold or $11,424,066 currency, and to the value of those in 1875, $15,596,524 gold, for merchandise which the Canadian reports show to have been exported from the United States, but which does not appear in the returns of this country. The average yearly value in gold of the imports and exports, from the formation of the government to 1850, was as follows:

YEARS.	Imports.	Exports of foreign products.	Exports of domestic products.
1789 to 1799..	$52,359,269	$15,175,257	$27,944,992
1799 " 1809..	93,351,628	37,827,500	37,287.530
1809 " 1819..	81,906,927	13,357,458	45,338,432
1819 " 1829..	80.220,651	23,326,438	52,832,653
1829 " 1839..	126,641,148	19,564,916	83,845,630
1839 " 1849..	119,678,698	13,233,998	110,840,752

The chief articles of import and of domestic export during the year ending June 30, 1875, with their values, were as follows:

IMPORTS.

Chemicals, drugs, dyes, and medicines..........	$10,272,571
Coffee..	50,591,488
Gold and silver, coin and bullion...............	20,900,717
Gums..	2,321,383

The total number of vessels entered in the foreign trade during the year ended June 30, 1875, was 27,961, with an aggregate tonnage of 11,692,810. Of these, 11,074, of 3,573,950 tons, were American, and 16,887, of 8,118,860 tons, were foreign; 1,028, of 1,141,734 tons, were American ocean steamers, and 1,246, of 3,142,723 tons, foreign ocean steamers. The total number cleared was 28,236, of 11,896,507 tons, including 11,216 American vessels, of 3,736,639 tons, and 17,020 foreign vessels, of 8,159,868 tons. Besides the above, 74,027 vessels, of 31,614,282 tons, entered, and 73,324, of 30,440,626 tons, cleared in the coastwise trade and fisheries. The extent of the merchant marine of the United States at different periods has been as follows:

YEARS.	Sail, tons.	Steam, tons.	Total, tons.
1790	478,377	....	478,377
1800	972,492	....	972,492
1810	1,424,783	....	1,424,783
1820	1,280,167	....	1,280,167

1874	71	22	655	995	404	2,147	432,725
1875	114	22	502	340	323	1,301	297,639

On June 30, 1875, there were employed in the cod and mackerel fisheries 1,259 vessels of 68,703 tons, and in the whale fisheries 165 vessels of 38,229 tons. The products of the year ending on that date were valued at $15,588,581, including $2,841,002 whale and $10,747,579 other fisheries. (See Fisheries.) The number and chief nationalities of emigrants arriving in the United States each year to the close of 1873 are given in the article Emigration. For the years 1874 and 1875 they were:

The whole number of customs districts in the United States is 112, each having a port of entry. There are also 15 interior ports of delivery, at which duties may be collected on appraised merchandise transported in bond from exterior ports of entry, viz.: Albany, N. Y.; Pittsburgh, Pa.; Parkersburg and Wheeling, W. Va.; Cincinnati, O.; Evansville, Ind.; Cairo and Galena, Ill.; Burlington and Dubuque, Iowa; Omaha, Neb.; Louisville, Ky.; Memphis and Nashville, Tenn.; and St. Louis, Mo. Of these the following have also been made ports of entry, to which merchandise may be transported directly without prior appraisement: Cincinnati, O.; Evansville, Ind.; Louisville, Ky.; Memphis, Tenn.; Pittsburgh, Pa.; and St. Louis, Mo. The railroad, canal, telegraph, and postal systems of the United States are described in the special articles on those subjects.—The wealth, taxation (not national), and public debt (not national) in 1860 and 1870 were as follows:

PARTICULARS.	1860.	1870.

—The several states of the Union, so far as their internal affairs are concerned, are supreme and independent, while for the common interests of all they delegate a portion of their powers to a central government, whose laws, so long as they are not in conflict with the constitution, are paramount to state authority. All powers not expressly granted by the constitution to the federal government, nor prohibited by it to the states, are reserved to the states respectively or to the people. The government consists of three branches, the legislative, executive, and judicial. The executive power is vested in a president, who together with a vice president is elected for four years by a college of electors, each state returning as many electors as it is entitled to have senators and representatives in congress. The present total number of electors is 366. The constitution provides that they shall be appointed in such manner as the respective legislatures may direct. At first they were generally chosen by the legislatures themselves, and this continued to be done in South Carolina till 1860; but now they are designated in all the states by popular vote at an election held every four years (counting for this century from 1800), on the Tuesday next after the first Monday in November. The electors meet in each state on the first Wednesday in December and cast their votes for president and vice president. On the second Wednesday in February the certificates of the votes thus cast are opened by the president of the senate in presence of the two houses of congress, when the votes are counted and the result declared. The official term of the officers declared elected begins on the 4th of March following. In case of the removal, death, resignation, or inability of the president, the vice president succeeds to the presidency, and, if the disability be not temporary, serves the remainder of the presidential term; and in case of the failure of both president and vice president, congress has authority to declare what officer shall act as president until the disability be removed or a president shall be elected. By act of congress approved March 1, 1792, the president of the senate *pro tempore*, or in case there be no president of the senate, the speaker of the house of representatives, is to act as president in such a case, and a new president is to be elected if the vacancy occurs more than five months before the end of the existing presidential term. Neither the president of the senate nor the speaker of the house has ever succeeded to the presidency under this law. Three presidents have died in office and been succeeded by vice presidents, viz.: William Henry Harrison in 1841, succeeded by Vice President John Tyler; Zachary Taylor in 1850, succeeded by Millard Fillmore; and Abraham Lincoln in 1865, succeeded by Andrew Johnson. When there is no election of president by the people for want of a majority of electoral votes for any one candidate, the house of representatives chooses the president from the three having the highest number of votes, the body of representatives from each state casting a single vote. Two elections by the house have occurred, viz.: in 1801 (under the original provision of the constitution, which required that the candidate having the highest number of votes for president should be president and the candidate having the next highest number vice president), when, there being a tie between Thomas Jefferson and Aaron Burr, the former was chosen president by the house; and in 1825, when John Quincy Adams was chosen. When the election results in no choice for vice president, that officer is chosen by the senate from the two who have received the highest number of votes. In 1837 Richard M. Johnson was thus chosen vice president by the senate. The president may be removed from office on impeachment for and conviction of treason, bribery, or other high crimes and misdemeanors. He is commander-in-chief of the army and navy, and of the militia of the several states when they are called into the actual service of the general government; and has power, by and with the advice and consent of the senate, to make treaties, and to appoint ministers and other public officers of the United States whose appointment is not otherwise provided for. He receives a salary of $50,000 (until 1873, $25,000) a year, and the vice president $10,000. All acts of congress must be presented to him before they can become law, and he may within ten days from its presentation return any bill of which he disapproves to the house in which it originated, stating his objections. If on reconsideration the bill is again passed by two thirds of each house, it becomes law. The president and vice president must be native-born citizens, 35 years of age, and 14 years resident within the United States. The president is assisted by a cabinet of seven ministers, called the secretaries of state, of the treasury, of the interior, of war, and of the navy, the attorney general, and the postmaster general, who are nominated by him and confirmed by the senate. They receive $8,000 a year each. These are the heads of the seven executive departments of the government, viz., state, treasury, interior, war, navy, justice, and post office. There are two assistant secretaries in the department of state, two in that of war, two in the treasury, and one in the interior department. There are three assistant postmasters general, and three assistant attorneys general in addition to the solicitor general, who is the first assistant of the attorney general. These officers are also appointed by the president with the consent of the senate. The principal duties of the secretary of state relate to foreign affairs. Besides other matters relating more directly to finance, the secretary of the treasury superintends the collection of duties and internal revenue; he also has general supervision of the lighthouses of the United States. There are in the department of the treasury a treasurer, commissioner of customs, commissioner of internal revenue, and comptroller of the currency; also a bureau of statistics, which collects and publishes statistics relating to commerce and navigation; and a bureau of the mint, which has under its control all the mints and assay offices of the United States. The secretary of the interior is charged with the supervision of public business relating to: 1, the census; 2, public lands, including mines; 3, Indians; 4, pensions and bounty lands; 5, patents; 6, custody and distribution of publications; 7, education; 8, government hospitals for the insane; 9, Columbia asylum for the deaf and dumb; also certain duties relating to the territories. The most important of these functions are intrusted to the commissioner of the general land office, commissioner of Indian affairs, commissioner of pensions, commissioner and assistant commissioner of patents, superintendent of public documents, and commissioner of education, who are appointed by the president with the consent of the senate. The department of agriculture (which is not an executive department), under the charge of a commissioner of agriculture, is designed to obtain and diffuse useful information relating to agriculture, and to procure and distribute new and valuable seeds and plants. Annual reports are made to congress through the president by the chiefs of the departments above named. The general supervision of Indian affairs is vested in a board consisting of not more than ten commissioners, who are appointed solely by the president "from men eminent for intelligence and philanthropy," and who serve without pecuniary compensation. They are required to supervise all expenditures for the Indians, and to inspect all goods purchased for them. Inspectors, not exceeding five, are appointed by the president to visit the Indian superintendencies and agencies as often as twice a year and investigate their affairs. There are four superintendents of Indian affairs, who exercise a general supervision and control over the official acts of all persons employed by the government in that service. The national legislature consists of a congress composed of a senate and house of representatives. The senate consists of two senators from each state chosen by the respective legislatures for six years, in such a way that one third of the whole body goes out of office every two years. The act of congress of 1866 provides that in every state each branch of the legislature shall first vote separately and *viva voce* for senator. These votes are declared in joint assembly on the following day, and if no candidate has received a majority vote of each house, both houses in joint assembly elect a senator by ballot. If a vacancy occur in the senate when the legislature of the state interested is not in session, it may be filled by appointment of the governor until the legislature next meets, when a senator is chosen for the unexpired term. The vice president of the United States is president of the senate *ex officio*, and the senate elects a president *pro tempore* to serve in his absence; the vice president has only a casting vote. A senator must be 30 years of age, nine years a citizen of the United States, and at the time of his election resident within the state for which he is chosen. The senate has sole power to try all impeachments. The house of representatives is composed of members chosen for two years by the people of each state; they must be 25 years of age, seven years citizens of the United States, and at the time of their election resident within the states for which they are chosen. The number of representatives in congress is fixed by the law of 1872 at 292, and they are apportioned among the several states according to their representative population, excluding Indians not taxed. The number of representatives in congress and of electoral votes of each state are as follows:

STATES.	Represen-tatives.	Electoral votes.	STATES.	Represen-tatives.	Electoral votes.

The admission of Colorado as a state with one representative and two senators will add three to the total number of electoral votes. Every state is entitled to at least one representative. New states admitted after the apportionment (which is made after each decennial census) elect representatives in addition to the limited number of 292, but such excess continues only till the next apportionment. There are also delegates, one from each organized territory, who are entitled to speak in the house, but not to vote. The election for representatives and delegates to congress is held biennially on the Tuesday next after the first Monday of November in even years. The house of representatives chooses its own speaker and other officers; has the sole power of impeachment; and originates all bills relating to revenue. Members of both senate and house receive $5,000 a year, and mileage at the rate of 20 cents for each mile of travel in going to and returning from the seat of government. The pay of the speaker of the house is $8,000 a year. The regular sessions of congress begin on the first Monday of December in each year, and extra sessions may be called by the president whenever he deems it necessary. The term of office of representatives, and consequently the duration of each congress, expires by law on the 4th day of March of every odd year. Congress has power to lay and collect taxes, imposts, and excises, which must be uniform throughout the United States; to borrow money on the credit of the United States; to regulate commerce with foreign nations, among the several states, and with the Indian tribes; to coin money; to define and punish piracy and offences against the law of nations; to declare war; to raise and support an army and navy; to provide for calling forth the militia when required; and to exercise exclusive legislation over the District of Columbia. Congress can make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech or of the press, or the right of the people peaceably to assemble and to petition the government for a redress of grievances. It has passed general laws of bankruptcy and for the protection of inventions, copyrights, and trade marks. (See BANKRUPT, PATENTS, COPYRIGHT, and TRADE MARK.) The judiciary comprises a supreme court, circuit courts, district courts, and the court of claims. There are also the supreme court of the District of Columbia and the territorial courts, the judges of which are appointed by the president. The former has jurisdiction corresponding to that of the state courts and also that of the federal district courts; the jurisdiction of the latter is specially defined by the acts providing for their creation. Besides these, each state has its own independent judiciary. The supreme court consists of a chief justice (salary $10,500) and eight associate justices (salary $10,000 each). It holds one session annually in Washington, beginning on the second Monday in October. The United States is divided into nine judicial circuits, as follows: 1, Maine, New Hampshire, Massachusetts, and Rhode Island; 2, Vermont, Connecticut, and New York; 3, Pennsylvania, New Jersey, and Delaware; 4, Maryland, Virginia, West Virginia, North Carolina, and South Carolina; 5, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas; 6, Ohio, Michigan, Kentucky, and Tennessee; 7, Indiana, Illinois, and Wisconsin; 8, Nebraska, Minnesota, Iowa, Missouri, Kansas, and Arkansas; 9, California, Oregon, and Nevada. There is a circuit judge (salary $6,000) resident in each circuit, and a justice of the supreme court visits each circuit for the purpose of holding circuit court. Circuit courts are held by the justice of the supreme court assigned to the circuit, or by the circuit judge of the circuit, or by the district judge of the district, or by any two of them sitting together. The United States is also divided into 57 districts, in each of which there is a district court composed of one judge, who resides in the district for which he is appointed. In many states the district is coextensive with the state; in others the state is divided into two or three districts. The court of claims consists of a chief justice and four associate judges; its sessions are held in Washington. All the judges of the federal courts are appointed for life by the president with the consent of the senate; but they may be removed for cause. (For the jurisdiction of the federal courts, see COURT, vol. v., pp. 432–'3.) The qualifications of voters in the United States are prescribed by the states respectively; the fifteenth amendment to the federal constitution provides that the right of citizens to vote shall not be denied or abridged on account of race, color, or previous condition of servitude. The executive power of each organized territory is vested in a governor, who is appointed for four years by the president of the United States with the consent of the senate, and receives a salary of $3,000. The secretary is appointed in the same manner and for the same period, and receives a salary of $2,500. The legislative power is vested in a council and house of representatives, chosen by the people for two years; the sessions are biennial. A delegate to congress is elected by the people in each territory for two years. The legislation of the territories is subject to revision by congress. The judicial power is vested in a supreme court consisting of a chief and two associate justices, who are appointed for four years by the president with the consent of the senate, and receive a salary of $3,000 each; in three district courts each held by a judge of the supreme court; and in inferior courts organized by the territory. Territories are admitted as states into the Union by special acts of congress. The District of Columbia is under the exclusive jurisdiction of congress. By act of June 20, 1874, the government is vested in a commission of three persons appointed by the president with the consent of the senate. All ministers to foreign countries are appointed by the president and confirmed by the senate.—The constitution forbids the suspension of the writ of *habeas corpus*, unless when in cases of rebellion or invasion the public safety may require it; the passing of any bill of attainder or *ex post facto* law; the imposition of any capitation or other direct tax except in proportion to the census, or of any tax or duty on articles exported from any state; and the passing of any commercial or revenue regulation giving a preference to the ports of one state over those of another state. No money can be drawn from the treasury except in consequence of appropriations made by law, and a statement of the public receipts and expenditures must be published from time to time. No title of nobility can be granted by the United States, and no person holding any office of profit or trust under them can without the consent of congress accept of any present, emolument, office, or title of any kind from any king, prince, or foreign state. The right of the people to bear arms may not be infringed; soldiers may not be quartered in any house in time of peace without the consent of the owner, nor even in time of war except in a manner to be prescribed by law. The persons, houses, papers, and effects of the people are exempt from search and seizure except under a warrant issued upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched and the persons or things to be seized. No person may be held to answer for a capital or otherwise infamous crime unless on a presentment or indictment of a grand jury, except in cases arising in the land or naval forces, or in the militia when in actual service in time of war or public danger; nor may any person be subject for the same offence to be twice put in jeopardy of life or limb; nor be compelled in any criminal case to be a witness against himself; nor be deprived of life, liberty, or property, without due process of law. In all criminal prosecutions, the accused shall enjoy the right to a speedy and public trial by an impartial jury of the state and district wherein the crime shall have been committed; to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining witnesses in his favor; and to have the assistance of counsel for his defence. Excessive bail may not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted. Private property may not be taken for public use without just compensation. No state can enter into any treaty, alliance, or confederation; grant letters of marque and reprisal; coin money, emit bills of credit, or make anything but gold and silver a legal tender for debts; pass any bill of attainder, *ex post facto* law, or law impairing the obligation of contracts; grant any title of nobility; or lay any imposts or duties on imports and exports, without the consent of congress, except what may be necessary for executing its inspection laws. The net produce of all imposts and duties laid by any state on imports or exports shall be for the benefit of the treasury of the United States. Without the consent of congress no state may lay any duty on tonnage; keep troops or ships of war in times of peace; enter into any agreement or compact with another state or with a foreign power; or engage in war unless actually invaded, or in such imminent danger as will not admit of delay. Treason against the United States consists only in levying war against them, or in adhering to their enemies, giving them aid and comfort. The punishment of treason is left to be defined by congress, but no attainder of treason shall work corruption of blood or forfeiture except during the life of the person attainted. Full faith and credit shall be given in each state to the public acts, records, and judicial proceedings of every other state, and citizens of each state are entitled to all the privileges and immunities of citizens in the several states. Slavery is prohibited by the thirteenth amendment of the constitution. All persons born or naturalized in the United States are declared to be citizens thereof, and every state is prohibited from making or enforcing any law which shall abridge the privileges or immunities of such citizens. New states may be admitted into the Union by congress, but no new state can be erected within the jurisdiction of any other state, nor any state be formed by the junction of two or more states or parts of states, without the consent of the legislatures of the states concerned as well as of congress. The several states have exclusive power to prescribe the qualifications of voters and state officers, and the form of their state government. The constitution only requires that the form of government be republican, and that no law or ordinance be passed which would conflict with any law of the United States. Congress has power to dispose of and make all needful rules and regulations respecting the territories or other property belonging to the United States. Amendments to the constitution may be proposed by two thirds of both houses of congress, or by a convention convoked by congress on the application of the legislatures of two thirds of the states; they become valid when ratified by the legislatures of or conventions in three fourths of the states.—The army of the United States comprises 25 regiments of infantry, 10 of cavalry, and 5 of artillery, besides a corps of engineers, &c. The chief officers are: the general (in 1876, William T. Sherman), annual salary $13,500; the lieutenant general (Philip H. Sheridan), $11,500; three major generals, $7,500 each; and six brigadier generals, $3,500 each. The United States is divided into four military divisions, which are respectively under the command of the lieutenant general and the three major generals. The division of the Atlantic, with headquarters in New York, constitutes but one department; that of the Missouri, with headquarters in Chicago, comprises the departments of Dakota, Missouri, the Platte, and Texas; that of the South, headquarters in Louisville, Ky., includes the departments of the South and of the Gulf; that of the Pacific, headquarters in San Francisco, the departments of California, the Columbia, and Arizona. The numerical strength of the army is about 25,000 enlisted men. The national armory is at Springfield, Mass. There are United States arsenals at Augusta, Ga.; Augusta, Me.; Benicia, Cal.; Fort Union, N. M.; Indianapolis, Ind.; Jefferson Barracks, Mo.; New York city (arsenal and agency); Old Point Comfort, Va.; Philadelphia, Pa.; Pikesville, Md.; Pittsburgh, Pa.; Rock Island, Ill.; San Antonio, Texas; Vancouver, W. T.; Washington, D. C.; Watertown, Mass.; and West Troy, N. Y. The soldiers' home, for honorably discharged soldiers of the regular army who have served 20 years or have been discharged for disability contracted in the service, is situated in the District of Columbia, near Washington. It is under the supervision of a board of commissioners consisting of the surgeon general, adjutant general, and commissary general of subsistence of the army. The national home for disabled volunteer soldiers is at Dayton, Ohio, and has branches at Augusta, Me., Milwaukee, Wis., and Hampton, Va. These homes are under the direction of a board of managers, and are maintained by annual congressional appropriations. (See PENSION.) In 1876 there were for the interment of soldiers and sailors 81 national cemeteries in the United States, most of them being near famous battle fields of the war. The total number of interments to 1875 was 306,053. The cemeteries were classified as follows:

FIRST CLASS.

Arlington, Va.
Andersonville, Ga.
Beaufort, S. C.
City of Mexico, Mexico.
Corinth, Miss.
Camp Nelson, Ky.
Chattanooga, Tenn.
Chalmette, La.
Fredericksburg, Va.
Gettysburg, Pa.
Hampton, Va.
Jefferson Barracks, Mo.
Little Rock, Ark.
Mound City, Ill.
Memphis, Tenn.
Murfreesboro, Tenn.
Marietta, Ga.
Nashville, Tenn.
Natchez, Miss.
Pittsburgh Landing, Tenn.
Poplar Grove, Va.
Port Hudson, La.
Richmond, Va.
Salisbury, N. C.
Soldiers' Home, D. C.
Vicksburg, Miss.

SECOND CLASS.

Alexandria, Va.
Alexandria, La.
Brownsville, Texas.
Baton Rouge, La.
Barrancas, Fla.
City Point, Va.
Culpeper, Va.
Fort Leavenworth, Kan.
Fort Smith, Ark.
Florence, S. C.
Fort Scott, Kan.
Knoxville, Tenn.
Mill Springs, Ky.
Mobile, Ala.
New Berne, N. C.
Philadelphia, Pa.
Raleigh, N. C.
Wilmington, N. C.
Winchester, Va.
Yorktown, Va.

THIRD CLASS.

Annapolis, Md.
Ball's Bluff, Va.
Battle Ground, D. C.
Beverly, N. J.
Camp Butler, Ill.
Cave Hill, Ky.
Cold Harbor, Va.
Crown Hill, Ind.
Cypress Hills, N. Y.
Danville, Ky.
Danville, Va.
Fayetteville, Ark.
Finn's Point, N. J.
Fort Donelson, Tenn.
Fort Gibson, Indian Ter.
Fort Harrison, Va.
Fort McPherson, Neb.
Fort St. Philip, La.
Fort Vancouver, W. T.
Glendale, Va.
Grafton, W. Va.
Jefferson City, Mo.
Keokuk, Iowa.
Laurel, Md.
Lebanon, Ky.
Lexington, Ky.
Loudon Park, Md.
New Albany, Ind.
Rock Island, Ill.
San Antonio, Texas.
Santa Fé, N. M.
Seven Pines, Va.
Springfield, Mo.
Staunton, Va.
Woodlawn (Elmira), N. Y.

The law provides for the enrolment in the militia of every able-bodied male citizen of the respective states between the ages of 18 and 45 years, except those specially exempted. The organization and control of the militia when not in active service are left to the respective states. The president is empowered to call out the militia whenever the United States is invaded, or in imminent danger of invasion from any foreign nation or Indian tribe, or in case of rebellion. (See MILITIA, vol. xi., p. 540.) In 1876 the navy comprised 147 vessels of 152,492 tons measurement, carrying 1,195 guns. Of these, 26 were sailing vessels, 26 ironclads, and 95 ordinary steam vessels, including 25 tugs. The chief officers on the active list are the admiral (in 1876, David D. Porter), annual salary $13,000; vice admiral (Stephen C. Rowan), salary $9,000 when at sea and $8,000 when on shore duty; 12 rear admirals, each receiving $6,000 a year when at sea and $5,000 on shore duty; 25 commodores, 50 captains, and 90 commanders. The whole field of naval operations in every part of the world is divided into six stations, each commanded by a rear admiral, designated as the European, the Asiatic, the South Pacific, the North Pacific, the South Atlantic, and the North Atlantic. There are United States navy yards at Kittery, Me.; Boston, Mass.; New London, Conn.; Brooklyn, N. Y.; League Island (Philadelphia), Pa.; Washington, D. C.; Norfolk, Va.; Pensacola, Fla.; and Mare Island, Cal. Nine naval hospitals are maintained by the United States, as follows: Annapolis, Md.; Brooklyn, N. Y.; Chelsea, Mass.; Mare Island, Cal.; Norfolk, Va.; Pensacola, Fla.; Philadelphia, Pa.; Washington, D. C.; and Yokohama, Japan. (See Navy.)—The national debt of the United States, past and present, has accrued chiefly in consequence of the war of the revolution, that of 1812, the Florida war, the Mexican war, and the civil war. The cost of the revolutionary war was estimated by Hamilton at $135,193,703 in specie; the estimated cost of the war of 1812 was $75,450,930, and of the Mexican war $82,232,745. Acquisitions of territory have added $72,200,000 to the debt, as follows: the purchase of Louisiana from France in 1803, for $23,500,000 (including certain claims in addition to the price of the territory); of Florida from Spain in 1819 for $6,500,000; the Texas cession in 1850, $10,000,000; the acquisition of California from Mexico in 1848, $15,000,000; the Gadsden purchase from Mexico in 1853, $10,000,000; and the purchase of Alaska from Russia in 1867, $7,200,000. In 1790 the secretary of the treasury reported that the aggregate foreign and domestic debt on Dec. 31, 1784, was $54,124,464; the state debts, including interest, were estimated at $25,000,000. The outstanding principal of the public debt of the United States on Jan. 1 of each year from 1791 to 1843 inclusive, and on July 1 from 1844 to 1875, has been as follows:

YEARS.	Amount.	YEARS.	Amount.
1791	$75,463,476	1804	$86,427,120
1792	77,227,924	1805	82,312,150
1793	80,352,634	1806	75,723,270
1794	78,427,404	1807	69,218,398
1795	80,747,587	1808	65,196,317
1796	83,762,172	1809	57,023,192
1797	82,064,479	1810	53,173,217
1798	79,228,529	1811	48,005,587

1842	20,601,226	1872	2,253,251,328
1843	32,742,922	1873	*2,234,482,993
1844	23,461,652	1874	*2,251,690,468
1845	15,925,303	1875	*2,232,284,531
1846	15,550,202		

In 1835 the country was entirely out of debt, the small amount unpaid having been provided for. The total amount of loans and treasury notes issued by the government previous to the year 1861 was $492,371,087, all of which has been paid, with the exception of $1,408,050, which has matured but has not been presented for payment. The whole amount of loans and treasury notes issued since 1861 is $5,011,818,908. Under the acts of Feb. 8, July 17, and Aug. 5, 1861, were issued $207,736,350 of bonds redeemable in 1881, bearing 6 per cent. interest payable semi-annually, and known as sixes of '81. Under the acts of July 17, 1861, June 30, 1864, and March 3, 1865, treasury notes to the amount of $970,087,250 were issued in denominations of $50 and over, bearing 7$\frac{3}{10}$ per cent. interest, and known as seven-thirties. With an unimportant exception, all of these have been paid or funded. Under the acts of Feb. 25, 1862, March 3, 1864, and Jan. 28 and March 3, 1865, $1,602,697,000 of coupon and registered bonds were issued, redeemable after 5 and payable in 20 years, bearing 6 per cent. interest payable semi-annually in coin, and known as five-twenties of '62, '64, and '65, and consols of '65, '67, and '68; outstanding, April 1, 1876, $701,318,300. Under the act of March 3, 1864, were issued $196,117,300 of "ten-forty" bonds, redeemable in 10 and payable in 40 years in coin, with 5 per cent. interest payable semi-annually; outstanding, $194,566,300. Under the acts of July 14, 1870, and Jan. 20, 1871, were issued $500,000,000 of 5 per cent. bonds payable in coin after 10 years, and the interest quarterly. Under the act of March 3, 1863,

---

* Included in these sums are certificates of deposit amounting to $31,730,000 in 1873, $58,760,000 in 1874, and $58,415,000 in 1875. These certificates are offset by notes held on deposit for their redemption, and should be deducted from the principal of the public debt in comparing with previous years.

$266,595,440 of compound interest notes were issued, payable in three years with 6 per cent. interest; outstanding April 1, 1876, $336,700. The acts of Feb. 25 and July 11, 1862, authorized the issue of $300,000,000 of legal-tender notes fundable into a bond bearing 6 per cent. interest in gold. The demand notes previously issued, $60,000,000, were also made a legal tender by the act of March 17, 1862. The act of March 3, 1863, authorized an additional issue of $150,000,000; and the right to exchange such notes for 6 per cent. bonds was limited to July 1, 1863. The act of June 30, 1864, provided that the total amount of such notes should not exceed $400,000,000, and such additional sum, not exceeding $50,000,000, as might be lawfully required for the redemption of temporary loans. The amount outstanding on April 1, 1876, was $370,823,645. (See MONEY, vol. xi., p. 743.) On Jan. 1, 1861, the debt amounted to $66,243,721. During the next six months it increased at the rate of about $4,000,000 a month; during the year beginning July 1, 1862, at the rate of about $36,000,000 a month; during the following year at the rate of $49,500,000 a month. Increasing more than $70,500,000 a month from Dec. 1, 1863, to April 1, 1865, and $84,400,000 a month during the five months following, it reached its maximum on Aug. 31, 1865, when it amounted to $2,845,907,626, composed as follows:

Funded debt	$1,109,568,192
Matured debt	1,503,020
Temporary loans	107,148,713
Certificates of debt	85,093,000
Five per cent. legal-tender notes	33,954,230
Compound interest legal-tender notes	217,024,160
Seven-thirty notes	830,000,000
United States notes (legal tenders)	433,160,569
Fractional currency	26,344,742
Suspended requisitions uncalled for	2,111,000

Of these obligations, $684,138,959 were a legal tender in the payment of all debts, public and private, except customs duties and interest on the public debt. The amount of legal-tender notes, demand notes, fractional currency, and national bank notes outstanding on Aug. 31, 1865, and annually thereafter, from Jan. 1, 1866, to Jan. 1, 1876, inclusive, was:

DATES.	UNITED STATES ISSUES.				National bank notes, including national gold bank notes.	Aggregate.
	Fractional currency.	Old demand notes.	Legal-tender notes.*	Total.		
August 31, 1865	$26,344,742	......	$433,160,569	$459,505,311	$176,213,955	$635,719,266

The refunding of the national debt was authorized by the acts of congress of July 14, 1870, and Jan. 20, 1871. The amount of six per cent. gold-bearing bonds outstanding on Jan. 1, 1870, was $1,886,349,800, and of five per cent. bonds $221,589,300. On Jan. 1, 1876, the former amounted to $1,017,615,400, and the latter to $670,384,750, showing a decrease in the funded debt of $419,938,950. The reduction in the total debt during this period (excluding $35,175,000 of special deposits of legal-tender notes) was $435,716,254. The temporary loans, certificates of indebtedness, seven-thirty notes, and all the items of the debt bearing interest in lawful money, with the exception of the navy pension fund, either have been paid, have matured and ceased to bear interest, or have been funded. The public debt outstanding on April 1, 1876, is shown in the following statement. Besides this, $64,623,512 of 6 per cent. bonds, maturing 30 years from their date, have been issued to the several Pacific railway companies, which are to pay them at maturity.

Debt bearing interest in coin:		
Bonds at 6 per cent.	$984,999,650 00	
Bonds at 5 per cent.	710,037,600 00	
		$1,695,037,250 00
Debt bearing interest in lawful money:		
Navy pension fund at 3 per cent.		14,000,000 00
Debt on which interest has ceased since maturity		9,183,360 26
Debt bearing no interest:		
Old demand and legal-tender notes	$370,823,645 50	
Certificates of deposit	34,230,000 00	
Fractional currency	42,604,893 71	
Coin certificates	32,337,600 00	
		479,996,139 21
Total debt		$2,198,216,749 47

The total receipts and expenditures of the government during each decade to 1860 were:

PERIODS.	RECEIPTS.		EXPENDITURES.	
	Net ordinary.	Gross.	Net ordinary.	Gross.
1791–1800	$56,800,000	$77,200,000	$34,000,000	$75,000,000
1800–1810	132,000,000	183,600,000	55,900,000	131,900,000
1810–1820	201,800,000	312,400,000	182,900,000	314,200,000
1820–1830	212,200,000	230,800,000	122,000,000	226,600,000
1830–1840	310,000,000	329,500,000	230,700,000	300,600,000
1840–1850	246,400,000	374,200,000	293,900,000	374,400,000
1850–1860	589,200,000	646,200,000	545,500,000	645,800,000

---

* No interest-bearing notes, but demand notes only, are included with legal-tender notes from Aug. 31, 1865, to Jan. 1, 1870.

The annual receipts and expenditures of the government for 20 years, with the chief sources and objects, have been as follows, the fiscal year ending June 30:

RECEIPTS.

YEARS.	Customs.	Internal revenue.	Direct tax.	Public lands.	Miscellaneous.	Net ordinary receipts.	Premiums.	Receipts from loans and treasury notes.	Gross receipts.

The receipts and expenditures of the post office department are not included in the above statement. They are given from 1790 to 1874 in the article POST, vol. xiii., p. 754. The receipts for the year ending June 30, 1875, were $26,791,360, of which $24,490,942 were for stamps, stamped envelopes, and postal cards. The expenditures were $33,611,309, of which $18,779,201 were for transportation of the mails, $10,464,746 for compensation of postmasters and clerks, $1,877,210 for compensation of letter carriers, and $724,186 for postage stamps. (For particulars concerning internal revenue, see TAXES, vol. xv., p. 589.) The total production of gold from 1848 to 1874, inclusive, was $1,282,927,092; of silver, $217,051,114. The coinage of the mints from 1793 to Jan. 1, 1876, was: of gold, $920,070,958; of silver, $169,669,963; of minor coinage, $12,717,198. Of this amount, $471,433,936 of gold, $116,153,632 of silver, and all of the minor, were coined at Philadelphia; and $390,427,157 of gold, and $19,175,425 of silver, coined at San Francisco. (See GOLD, SILVER, and MINT.)—A law for the establishment of a national banking system was passed by congress in February, 1863, and was superseded by the national bank act of June 3, 1864. (See BANK, vol. ii., p. 281.) The act of June 20, 1874, authorized the retirement of the circulation of national banks, and the surrender of bonds held as security therefor, upon the deposit of legal-tender notes in the treasury for the amount of the circulation thus retired. It also repealed the provision requiring a reserve on circulation, and provided for a system of redemption of national bank notes in the treasury department. The act of Jan. 14, 1875, provides for the unlimited issue of circulating notes to national banks, subject to the provisions of existing laws, and the reduction of the legal-tender notes at the rate of 80 per cent. upon the amount of additional bank notes issued, until the legal-tender notes shall be reduced to $300,000,000. The following table exhibits

---

* Including the Geneva award, $15,500,000.

The total amount of circulation on March 1, 1876, was $342,819,073, of which $24,452,580 is being retired, lawful money having been deposited with the treasurer for that purpose. The remainder of the circulation, $318,366,493, is secured by $356,680,150 of United States bonds, the value of which in currency on March 1, 1876, was $427,947,224, and in gold $374,582,200. The following statement shows by geographical divisions the average number of national, state, private, and savings banks during the six months ending May 31, 1875, with their average capital and deposits in millions of dollars:

—There is no national system of education in the United States, and the general government exercises no control over public schools and makes no regular provision for their support, except that the military academy at West Point, N. Y., the school of artillery at Fortress Monroe, Va., and the naval academy at Annapolis, Md., are wholly supported and controlled by the government. Officers are also detailed by the government to give military instruction in certain colleges. (See MILITARY SCHOOLS, and ANNAPOLIS. For the aid given by the government for the advancement of learning, see SMITHSONIAN INSTITUTION.) The regulation of all matters pertaining to education is left entirely to the states, each of which maintains a system of public instruction independently of the others. In each state free common schools are provided by law for all persons of school age. But the general government has made liberal provision for purposes of education by various grants of land, dating as far back as 1803. More than 75,000,000 acres of land have thus been set apart for common schools and universities, including 7,830,000 reserved by act of congress passed July 2, 1862, for the establishment in the several states of colleges for the benefit of agriculture and the mechanic arts. The organization and control of these institutions are given to the respective states, and many of them are in operation. The following are the most important facts relating to the common schools in the United States in 1874, as reported by the bureau of education, the number of states in the Union being 37, and of territories, including the District of Columbia, 11:

---

* The total amount of circulation outstanding on Oct. 1, 1875 (2,302 banks), was $347,900,082, which amount includes the notes in circulation of banks which have failed, are in liquidation, and have deposited legal-tender notes under the act of June 20, 1874.

The charitable educational institutions embraced, besides those mentioned for the blind, deaf and dumb, and feeble-minded, 56 reform schools, 156 orphan asylums, 21 soldiers' orphans' homes, 9 infant asylums, and 57 miscellaneous charities. There were 26 industrial schools, with 259 teachers and 6,096 pupils. Art instruction, including training in industrial art, was afforded by 26 institutions. There were 44 museums of natural history, and 27 of art. (See Education, vol. vi., pp. 424–431.) No general provision is made by the United States for the treatment of the insane, idiotic, deaf and dumb, or blind. Such institutions are organized and maintained by the states and by corporations. (See Blind, Deaf and Dumb, Idiocy, and Insanity.) There is a government hospital for the insane in the District of Columbia, intended for the treatment of the insane of that district and of the army and navy. The superintendent is appointed by the secretary of the interior. The Columbia deaf and dumb institution is intended primarily for the deaf and dumb of the District of Columbia; but pupils residing in the states, not exceeding 40 in number, may be admitted to the collegiate department without charge for tuition. For an account of the charitable and reformatory institutions maintained or aided by congress in the District of Columbia, see District of Columbia, and Washington. United States prisoners are confined in state or territorial prisons. For the prison systems of the states and the mode of treating paupers, see Prisons and Prison Discipline, and Pauperism; see also Reformatories.—The total number of libraries in 1870 was 164,815, having 45,528,938 volumes. Of these, 108,800 with 26,072,420 volumes were private, and 56,015 with 19,456,518 volumes other than private. They were classified as follows: 1 congressional library, with 190,000 volumes; 14 departmental, 115,185; 53 state and territorial, 653,915; 1,101 town, city, &c., 1,237,430; 1,073 court and law, 425,782; 14,375 school, college, &c., 3,598,537; 33,580 Sabbath school, 8,346,153; 4,478 church, 1,634,915; 47 of historical, literary, and scientific societies, 590,002; 9 of charitable and penal institutions, 13,890; 43 of benevolent and secret associations, 114,581; and 1,241 circulating, 2,536,128. In 1876 the library of congress had more than 300,000 volumes. (See Library, vol. x., p. 404.)—The whole number of newspapers and periodicals in 1870 was 5,871, having an aggregate circulation of 20,842,475, and issuing annually 1,508,548,250 copies. There were 574 daily, with a circulation of 2,601,547; 107 tri-weekly, 155,105; 115 semi-weekly, 247,197; 4,295 weekly, 10,594,643; 96 semi-monthly, 1,349,820; 622 monthly, 5,650,843; 13 bi-monthly, 31,650; and 49 quarterly, 211,670. In 1875 the total number was reported at 7,870, including 718 daily, 80 tri-weekly, 107 semi-weekly, 6,957 weekly, 24 bi-weekly, 106 semi-monthly, 802 monthly, 8 bi-monthly, and 68 quarterly. (See Newspapers, vol. xii., p. 342.)—There is no established or state church in the United States. The most numerous denominations are the Methodists, Roman Catholics, Baptists, and Presbyterians, which are generally found in all parts of the country, though the number of Presbyterians is not great in New England, and the Baptist denomination is not relatively so strong there as in other parts of the country. But a small proportion of the Roman Catholics are of American parentage, being mostly of Irish, German, and French nativity. Of the 2,887 Congregational organizations reported by the census of 1870, 1,400 were in New England and 1,178 in New

York, Illinois, Ohio, Iowa, Wisconsin, and Michigan. The greatest numerical strength of the Friends is in Pennsylvania, though the denomination is well represented in Ohio, New York, Iowa, Indiana, New Jersey, Massachusetts, North Carolina, and Maryland. The Jews are found in most of the states, chiefly in the largest cities, the greatest numbers being in New York, Pennsylvania, Illinois, and California. More than a third of all the Lutherans were reported in Pennsylvania and Ohio. Of the 72 Moravian organizations, 15 were in Pennsylvania, 13 in Wisconsin, 10 in North Carolina, 6 each in New York and Minnesota, and 5 in Iowa. The Mormons are almost exclusively in Utah. Of the 471 organizations of the Reformed church in America (late Dutch Reformed), 304 were in New York, 97 in New Jersey, and 22 in Michigan; and of the 1,256 of the Reformed church in the United States (late German Reformed), 712 were in Pennsylvania and 288 in Ohio. Of the 18 Shaker organizations, 15 were in Maine, Massachusetts, New Hampshire, New York, and Ohio. More than half of the Spiritualists are in Massachusetts and Michigan. Of the 331 Unitarian societies, 180 were in Massachusetts, 23 in New Hampshire, and 22 in New York. Seven Chinese religious organizations were reported in California. The total number of religious organizations, as reported by the census of 1870, was 72,459, having 63,082 edifices with 21,665,062 sittings, and property valued at $354,483,581. The denominations were represented as follows:

DENOMINATIONS.	Organizations.	Edifices	Sittings.	Property.
Baptist, regular	14,474	12,857	3,997,116	$39,229,221

Among the miscellaneous denominations were 7 Chinese and 2 Greek organizations in California; 1 Bible Communist in Connecticut and 2 in New York; 1 Catholic Apostolic each in Connecticut, Illinois, and Massachusetts, and 2 in New York; 1 Sandemanian in Connecticut; 1 Plymouth church in Massachusetts; 1 Bible Christian and 1 Schwenkfelder in Pennsylvania; and 1 Huguenot in South Carolina.

—History. When first visited by the Europeans, the country now comprised within the United States was exclusively inhabited by the red or copper-colored race commonly called American Indians. Of the origin of these people nothing is positively known, though their own vague traditions and their general resemblance to the tribes of N. E. Asia give a certain degree of plausibility to the theory that their ancestors came to America by way of Behring strait or the Aleutian islands. There is reason to believe that these savages were not the first occupants of the land, in almost every part of which, and especially in the valley of the Mississippi, are found monuments consisting of mounds and other earthworks of great extent, which must have been erected by an unknown and long extinct race. In physical appearance, manners, customs, religion, and social and political institutions, the Indians were so strikingly alike as to form but one people; yet they were divided into a multitude of tribes almost perpetually at war with each other, and speaking a great variety of dialects. While in possession of its savage aborigines, the country from the Mississippi to the Atlantic, and from the lakes to the gulf of Mexico, with comparatively slight exceptions, was one vast forest, inhabited by wild beasts, whose pursuit formed the principal occupation of the Indians, and gave them their chief means of subsistence and clothing. (See American Antiquities, American Indians, and American Indians, Languages of the.) According to the Scandinavian sagas, Leif, a Norwegian, sailed about 1001 from Iceland for Greenland, but was driven southward by storms till he reached a country called Vinland, from the wild grapes he found growing there. Other Scandinavian adventurers followed him, and made settlements, none of which were permanent. By many writers Vinland is supposed to have been Rhode Island or some other part of the coast of New England, but of its real position nothing is certainly known. If these northern legends be rejected as too vague to afford a basis for history, we must conclude that the territory now comprised within the United States was first visited by Europeans about five years after Columbus discovered the West Indies. In 1497 John Cabot, a Venetian, commanding an English ship under a commission from Henry VII., sailed from Bristol westward, and on June 24 discovered land (coast of Labrador), along which he coasted to the southward nearly 1,000 m., landing at various points, and planting on the soil the banners of England and of Venice. In 1498 his son Sebastian Cabot sailed with two ships from Bristol in search of a northwest passage to China;

but finding the ice impenetrable, he turned to the south and coasted along as far as the entrance of Chesapeake bay. A few years later, about 1508, it is probable that Verrazzano, a Florentine in the French service, made a cruise on the coast of North America; but there is no authentic account of his discoveries, the letter over his signature addressed to Francis I. and long received as genuine being now suspected to be spurious. In 1513 the Spaniard Ponce de Leon discovered Florida, and took formal possession of the country near where St. Augustine now stands; but on attempting afterward to plant a colony, he was repulsed and mortally wounded by the natives. In 1539 took place the famous expedition of the Spaniard De Soto, who landed with several hundred followers in Tampa bay on the west coast of Florida, and fought his way in the course of two years through the region which now forms the states of Georgia, Alabama, and Mississippi, to the river Mississippi, beyond which he penetrated for about 200 m., and to which he returned to die in 1542. After his death his discouraged followers descended the river in boats, and crossed the gulf to the Spanish settlements in Mexico. For a long period no further attempt was made by the Spaniards to colonize Florida. But in 1562 the French Calvinists, under the direction of Admiral Coligni, endeavored to found there a colony which might become a place of refuge for the persecuted Huguenots. Charles IX. conceded an ample charter, and an expedition under Jean Ribault made a settlement at Port Royal in South Carolina, the name of Carolina being then first given to the country in honor of King Charles. This colony was soon abandoned, and another, composed also of Protestants, was planted on the banks of the St. John's in Florida, which in 1565 was surprised and massacred by the Spaniards, who in the same year founded St. Augustine, the first permanent settlement in the United States.—The discoveries of the Cabots had given the English crown a claim to North America, which, though not prosecuted for nearly a century, was never relinquished, and which in the reign of Elizabeth led to efforts at colonization on a large scale. In 1585 an expedition sent by Sir Walter Raleigh made a settlement on Roanoke island in North Carolina, which failed so utterly that in a few years not a trace of it remained. In 1602 Bartholomew Gosnold effected a settlement on the Elizabeth islands in Massachusetts, which was abandoned the same year. James I. in 1606 established two great divisions in the American territory claimed by England: South Virginia, extending from Cape Fear to the Potomac, and North Virginia, from the mouth of the Hudson to Newfoundland. Two companies were formed in England for the colonization of America: the London company, to which was granted South Virginia, and the Plymouth company, to which was granted North Virginia; and it was agreed that the region between the Potomac and the Hudson should be neutral ground on which either company might make settlements. The London company sent out three ships and 105 emigrants, who entered Chesapeake bay, and founded on May 13, 1607, the commonwealth of Virginia by building Jamestown on James river, both names being given in honor of the English king. Capt. Newport commanded the expedition, but the master spirit of the enterprise was the celebrated Capt. John Smith. The natives were conciliated by the marriage of Pocahontas, the daughter of their king or principal chief Powhatan, to an Englishman, and remained friendly for some years. The government of Virginia was at first retained by the king in the hands of councils subject to his appointment or control; but after repeated changes the constitution was at length so framed that a house of burgesses chosen by the people was instituted, which met for the first time July 30, 1619. This was the beginning of representative government in America. In August, 1619, a Dutch man-of-war entered James river, and sold 20 Africans to the planters, thus introducing slavery into the colony; and in 1621 the cultivation of cotton was begun. Capt. John Smith had returned to England in 1609, and in 1614 sailed again for America; and having examined the coast from the Penobscot to Cape Cod, he named the country New England. On his return home he published a map and description of New England, which, together with his personal representations of the advantages of emigration, excited much enthusiasm in England for colonizing America; and a patent was obtained from the king for a new company incorporated as "the council established at Plymouth in the county of Devon for the planting, ruling, ordering, and governing New England in America," which gave the planters absolute property, with unlimited jurisdiction, the sole powers of legislation, and the appointment of all officers and all forms of government, over the territory, extending in breadth from the 40th to the 48th degree of north latitude, and in length from the Atlantic to the Pacific. The first English settlement within its limits, however, was established without the knowledge of the corporation and without the aid of King James, by the "pilgrim fathers of New England," a body of Puritans (102 in number) who, led by John Carver, William Brewster, William Bradford, Edward Winslow, and Miles Standish, sailed from England, Sept. 6, 1620, in the Mayflower, a vessel of 180 tons burden. They anchored first at Cape Cod (Nov. 9), and on Dec. 11 (O. S.) an exploring party landed at a harbor in Massachusetts bay, where the Mayflower anchored a few days afterward. Here they began to build a town, which they called Plymouth in memory of the hospitalities received at the last English port from which they had sailed. The government of the colony was strictly republican. The governor was elected by the people, and restricted by a council of five (afterward seven) assistants. The legislature at first comprised the whole body of the people, but as population advanced the representative system was adopted. The foundation of the Plymouth colony was followed by that of Massachusetts Bay, where Salem was settled by John Endicott in 1628. A reënforcement of 400 colonists landed in 1629. In 1630 a fleet arrived with about 700 additional emigrants, with John Winthrop as governor, and Thomas Dudley as deputy governor. In September of the same year they settled Boston, which they named in honor of the town in England from which came their minister, the Rev. John Cotton. In 1692 Plymouth colony was united to Massachusetts. While these settlements on Massachusetts bay were in progress, Sir Ferdinando Gorges and John Mason obtained a patent for a territory called Laconia, extending from the Atlantic to the St. Lawrence and from the Merrimack to the Kennebec, and settled Portsmouth and Dover in New Hampshire in 1623. In Maine a French colony had been planted in the island of Mount Desert as early as 1613, which was soon broken up by an expedition from Virginia; and the first permanent English settlements in Maine were made at Monhegan in 1622 and at Saco about the same time, or according to Bancroft, probably at the mouth of the Pemaquid in 1626. These settlements ultimately fell under the jurisdiction of Massachusetts, and Maine continued to form a part of that commonwealth till 1820. Connecticut was colonized in 1635–'6 by emigrants from Massachusetts, who settled at Hartford, Windsor, and Wethersfield, though a trading post had been established at Windsor somewhat earlier, and the Dutch, who claimed the territory, had built a fort and trading house at Hartford in 1633. Rhode Island was first settled at Providence in 1636 by Roger Williams, who had been exiled from Massachusetts for maintaining religious and political opinions at variance with those of the rulers of that colony. In September, 1609, Henry Hudson, an Englishman in the service of the Dutch East India company, entered New York harbor and went up the river to which his name has been given, exploring it beyond the mouth of the Mohawk. The region thus discovered was claimed by Holland and named New Netherland; and in a few years trading posts were erected at Fort Orange (now Albany) and on Manhattan island. In 1623 permanent settlements were made at Fort Orange and at New Amsterdam on Manhattan island, on the present site of the city of New York. The Dutch settlements gradually spread up the river, and eastward to the Connecticut, and westward and southward to the Delaware. On the Delaware they came in collision with the Swedes, who had settled there in 1638 and occupied both banks nearly to the site of Philadelphia, and named their settlements New Sweden. They were finally expelled in 1655 by a Dutch army. The English claimed the whole country under the right given by Cabot's discovery, and, after much diplomatic controversy protracted through nearly half a century, at length ended the contest by seizing New Amsterdam in 1664, and with it the whole of New Netherland. The province in the same year had been granted by Charles II. to his brother the duke of York and Albany, in whose honor the name of New Amsterdam was changed to New York, which also became the name of the province, while Fort Orange became Albany. New Jersey at this time acquired its distinctive name from Sir George Carteret, who had been governor of the island of Jersey, and in conjunction with Lord Berkeley had purchased the territory from the duke of York and made it a separate colony. In 1681 the territory west of the Delaware was granted to William Penn, who colonized it chiefly with Friends or Quakers, and founded Philadelphia in 1682. Pennsylvania soon became one of the most flourishing of the colonies, and was honorably distinguished among them for the kindness and justice of its treatment of the Indians, and its consequent exemption for nearly a century from savage warfare. About 1730 a large immigration of Germans began, which peopled several counties and gave a peculiar character to the population of the province. The country between the southern line of Pennsylvania and the Potomac was early called Maryland, in honor of Henrietta Maria, queen of Charles I. The first settlement within its limits was made in 1631 by Capt. William Clayborne, with a party of men from Virginia, on Kent island in Chesapeake bay. In 1632 Charles I. granted the province by a charter to Cecilius Calvert, Lord Baltimore, who sent out in 1633 a colony of about 200 persons, nearly all of them Roman Catholic gentlemen and their servants, led by the brother of the lord proprietor, Leonard Calvert, who became the first governor of the province. They landed on St. Mary's river, March 27, 1634, and began a settlement. In 1649 the assembly passed the memorable act by which Christians of all sects were secured in the public profession of their faith, and allowed to worship God according to the dictates of their own consciences. The first permanent settlement in North Carolina appears to have been made about 1663, on Albemarle sound, by emigrants from Virginia. The first permanent settlement in South Carolina was made in 1670 by colonists from England on the Ashley river, near the site of Charleston, which began to be settled about the same time. The territory S. of Virginia had been granted in 1663 by Charles II., under the name of Carolina, to Clarendon, Monk, and others as proprietaries. A constitution for the government of the country, framed by the philosopher Locke, was adopted by the proprietaries in 1670; but, being impracticable, it never completely went into operation, and was abrogated in 1693. In 1729 the king bought out the proprietors and divided the colony into two, called respectively North and South Carolina. The present state of Georgia originally formed part of Carolina, but in 1732 George II., in honor of whom it was named, granted the territory to a corporation entitled "the trustees for settling the colony of Georgia." In the same year a colony of about 120 persons sailed for the new province, under the direction of Gen. James Oglethorpe, and in February, 1733, founded Savannah.—In the course of little more than a century from the settlement of Jamestown, 13 permanent colonies were thus founded by the English within the present limits of the United States. Within the same limits the Spaniards had also settled in Florida and New Mexico, and the French had established posts in Michigan, in Illinois, and in Louisiana near the mouth of the Mississippi. Though agriculture was the chief pursuit of the colonists, manufactures and commerce were not wholly neglected. But as early as 1660 the mother country began to hamper their trade with navigation acts designed to compel the commerce of the Americans to pass exclusively through English hands. The house of commons in 1719 declared "that the erecting of manufactories in the colonies tended to lessen their dependence upon Great Britain," and laws were accordingly enacted prohibiting or restricting manufactures. Prompt attention was paid to education. Provision was made for a school in Virginia in 1621, and in 1692–'3 William and Mary college was established at Williamsburg. A school was founded in New Amsterdam in 1633. Harvard college in Massachusetts was founded in 1636, and Yale college in Connecticut in 1700; the college of New Jersey was incorporated in 1746, and King's (now Columbia) college in New York in 1754. In the New England colonies, as soon almost as they were founded, laws were enacted providing for a liberal system of common schools.—The details of colonial history being given in this work under the names of the individual states, we shall only notice here the most prominent events of general interest, which may be classed under the three heads of Indian wars, French wars, and political struggles against the English government. The Indians at first received the whites as friends; but the steady encroachments of the settlers on their hunting grounds and other causes led at length to war, though to the last a few tribes continued faithful friends to the Europeans. The first serious encounter took place in 1622, after the death of the friendly Powhatan, when a general conspiracy of the Indians of Virginia broke out in a bloody massacre, in which in one hour about 350 of the English fell beneath the tomahawk. The colonists were victorious in this contest, and again in 1644–'6, when the Virginian tribes made their last struggle for independence, led by Opechancanough, who was captured and kept in prison till he died. In 1636 the powerful Pequot tribe began hostilities in Connecticut, which resulted in its destruction in 1637 by Massachusetts and Connecticut troops. In 1675 the famous Pometacom, sachem of the Wampanoags, or King Philip as he was called by the English, effected a general combination of the aborigines against the colonists. A terribly destructive war ensued, which for some months threatened the extermination of the European population of New England, but was finally ended by the defeat and death of Philip in 1676. The Carolinas became involved in a fierce and sanguinary struggle with the Corees and Tuscaroras in 1711, and with the Yemassees in 1715, in both of which the whites were victorious. Toward the close of the 17th century the hostile Indians on the northern and western frontiers began to receive powerful aid and encouragement from the French in Canada, who, whenever their mother country was at war with England, carried on hostilities with the English colonies, and frequently, accompanied by their savage allies, made destructive inroads into New England and New York. In one of these incursions, in 1689, Dover in New Hampshire was burned by the Indians, and the inhabitants were killed or carried away captive; and in 1690 a similar fate was inflicted on Schenectady in New York, by a party from Montreal. A few years later (1704–'8) Deerfield and Haverhill in Massachusetts were destroyed, with hundreds of men, women, and children, by bands led by Hertel de Rouville, a French officer. Father Marquette, Louis Joliet, Robert Cavelier de la Salle, and other missionaries and adventurers, had carried the cross and the standards of France through the wilderness, from the St. Lawrence and the great lakes to the Mississippi and the gulf; and gradually the English settlements on the Atlantic were flanked on their western side by a chain of French posts. This threatening lodgment of the French in the rear of their American colonies greatly excited the jealousy of the English, who, under the charters granted by James I., claimed dominion westward from the Atlantic to the Pacific, south of the latitude of the north shore of Lake Erie, while the French claimed all the territory watered by the Mississippi and its tributaries under the more plausible title of having made the first explorations and settlements. But the earliest conflict between the two nations in America arose not from any colonial quarrel, but from the revolution of 1688, and is known as King William's war. It lasted seven years, and during its continuance the colonies suffered exceedingly from the incursions of the French and their Indian allies. In retaliation for these attacks efforts were made by the colonists to conquer Canada, against which in 1690 two expeditions were sent, one from Massachusetts under Sir William Phips, and another from Connecticut and New York under Gen. Winthrop, neither of which accomplished anything of importance. The war was terminated by the treaty of Ryswick, Sept. 20, 1697, but peace was not long maintained. The war of the Spanish succession involved in its hostilities the French and English in America (1702), where the contest is known as Queen Anne's war. Its effects were chiefly felt in New England, whose whole western frontier was ravaged by the Indians to such an extent that most of the remote settlements were destroyed or abandoned. In 1707 an ineffectual attack was made upon the French colony of Acadia; but in 1710 an expedition from Boston conquered it and annexed it to the English empire, under which it received the name of Nova Scotia. In 1711 a powerful armament of English and New England troops, under Sir Hovenden Walker, attempted the conquest of Canada by sea, but failed, as did another expedition which at the same time marched from Albany to attack Montreal. The peace of Utrecht (April 11, 1713) terminated hostilities, which were not resumed for 30 years. At the expiration of that period the war of the Austrian succession broke out in Europe, and spread to America, where it is known as King George's war. Its principal event was the capture of Louisburg, the chief stronghold of the French in America, which was taken June 17, 1745, by a force from New England led by William Pepperell, a wealthy merchant of Maine. This exploit excited much enthusiasm in England as well as in the colonies, and gave the Americans an idea of their own military strength which had an important influence in the future. The war ended by the treaty of Aix-la-Chapelle, Oct. 18, 1748, and Louisburg was restored to the French. Disputes having arisen with the French on the Ohio, an expedition under Washington was sent toward that river, which on May 28, 1754, cut to pieces a French detachment under Jumonville, who was slain. This affair began the long contest known in America as the French and Indian war (nearly simultaneous with the seven years' war in Europe). Hostilities were waged in America for two years before war was formally declared between France and England. In 1755 four expeditions were undertaken against the French. Gen. Braddock, with a force of regulars and provincials, the latter commanded by Washington, proceeded against Fort Duquesne on the Ohio; but about 10 m. from that post he fell into an ambush, and was defeated and mortally wounded. The army was withdrawn from danger chiefly by the steadiness and skill of Washington and his provincials, who covered the retreat. The result of this expedition shook the confidence of the people in the prowess of the British soldiery, and gave Washington a hold on popular esteem and confidence which was never afterward shaken. An expedition against Niagara and Frontenac on Lake Ontario, commanded by Gov. Shirley of Massachusetts, also failed. An attack on the French posts near the head of the bay of Fundy, led by Gen. Winslow, a New Englander, resulted in their capture and the expulsion of the French inhabitants from Acadia. The fourth expedition, composed chiefly of New England troops, was led by Sir William Johnson against Crown Point. It encountered the enemy at the head of Lake George, and in one day, Sept. 8, suffered a repulse and gained a complete victory, in which the French commander Dieskau was incurably wounded and made prisoner. Johnson failed to follow up this success, and the campaign of 1755 ended on the whole more favorably for the French than for the English. The energy and ability of the marquis de Montcalm, who succeeded Dieskau as commander-in-chief in Canada, gave during the next two years a still more marked superiority to the French arms. Oswego, with an immense amount of military stores, was captured by them in 1756; and Fort William Henry, at the head of Lake George, was compelled to surrender in 1757, an event long remembered from the massacre of part of the garrison after the capitulation by Montcalm's Indian allies. In 1758 the current of affairs, under the management of the new English premier William Pitt, was reversed. Louisburg was taken after a siege of seven weeks by Generals Amherst and Wolfe; Fort Frontenac was captured by Col. Bradstreet, with a provincial force; and Fort Duquesne met the same fate from an expedition of which Washington was one of the commanders. These advantages, however, barely counterbalanced the repulse of an attack on Ticonderoga made by a powerful army under Gen. Abercrombie and Lord Howe, in which the latter officer fell at the head of his troops, while the former was obliged to retreat with a loss of 2,000 men. Abercrombie was promptly superseded by Amherst, before whose approach in 1759 the French fled from Ticonderoga and Crown Point without striking a blow. Almost at the same time Niagara was taken by Sir William Johnson, and a large force sent to its relief was completely routed. The crowning exploit of the campaign and of the war was the taking of Quebec by an army led by Gen. Wolfe, after a battle on the plains of Abraham (Sept. 13), in which both Wolfe and Montcalm were mortally wounded. The surrender of Quebec virtually decided the contest in America, though it continued in Europe and on the ocean till 1763, when by the treaty of Paris Canada and its dependencies were formally ceded to Great Britain. The transfer from the French to the English of the posts between the great lakes and the Ohio led to a war with the Indian tribes, of which the master spirit was Pontiac. It broke out in May, 1763, and lasted several years. Detroit was besieged, and many posts were captured and their garrisons put to death. (See PONTIAC.)—The termination of this war left the colonies poor and exhausted, for their contributions in men and money had been very large, and they had suffered severely from the enemy during the mismanagement of the first half of the contest. Nevertheless they had gained greatly by the struggle. The conquest of Canada, of Louisburg, and of the military posts on their western frontier, extinguished their chief source of anxiety and danger, and freed them for ever from any serious dread of the Indians, who were really formidable only when supported by the French. Then, too, the incapacity of the English generals and the defeats sustained by large bodies of English troops had materially weakened their superstitious reverence for the power of the mother country, while their own exploits in the war had given them a confidence in their strength hitherto unfelt. The general characteristics of the people were intelligence, industry, and a high degree of moral and religious culture. They were descended for the most part from intelligent and enterprising ancestors, who had emigrated from the old world either to secure to themselves greater freedom to worship God or better opportunities to acquire competence or wealth. The passage across the Atlantic was tedious and expensive, and life in the new settlements hard and perilous. The lazy, the timid, the improvident, the brutally ignorant, shrank from the terrors of the sea and the wilderness, and the vast majority of the emigrants were of the respectable and energetic middle class. Religious influences operated powerfully, not only in giving an impulse to emigration, but on the character of the emigrants in their new homes; and not only on the Puritans, Huguenots, and Quakers, who came avowedly from the highest motives, but on vast bodies of churchmen, Dutch Calvinists, and Scotch-Irish Presbyterians. Much care was devoted to the education of children, and especially to training them in a knowledge of the Bible and the catechism, and in reverence for the sabbath. In Virginia the laws enacted that in every settlement there should be "a house for the worship of God." Absence from church was punished by a fine, and travelling or shooting on the sabbath was forbidden. In the Carolinas there were similar laws, and in Pennsylvania acts were passed against "stage plays, playing of cards, dice, May games, masques, and balls." Similar also was the legislation of the New England colonies, where in addition at some periods sumptuary laws and laws regulating the use of tobacco were in force. The spirit of political freedom was strongly developed among the colonists, and republican ideas and feelings transmitted from the period of the commonwealth in England were widely diffused, though at the same time a warm attachment existed for the mother country and a devoted loyalty to the crown. This attachment was disinterested, for though England afforded protection during the wars with the French, these wars, with the single exception of that recently concluded, had originated in Europe, and were waged for objects with which America had neither concern nor sympathy. In many other respects the connection was injurious to the colonies. Their trade and manufactures were systematically restricted for the selfish benefit of England; but though these oppressive enactments were heavily felt by the colonists, they made no resistance so long as the imperial authority confined itself to measures which, however harsh or injurious, were not clearly unconstitutional. But in 1761 parliament authorized sheriffs and officers of the customs to use "writs of assistance" or general search warrants which empowered them to enter stores and private dwellings and search for merchandise which it was suspected had not paid duty. These writs were first used in Massachusetts, where they roused great excitement and opposition. Obedience was refused to them on the ground of illegality, and a trial ensued in which the eloquent James Otis, the advocate general of the crown, refused to defend them, but resigned his office and appeared in behalf of the people. His speech made a profound impression. The judges evaded a decision, and the writs, although secretly granted, were never executed. In Virginia two years later occurred a collision between the royal prerogative and the colonial legislation on the subject of dues to the clergy, in which the cause of the colony was defended by Patrick Henry. It was at length decided in England to tax the colonies directly in spite of all their protests, and the stamp act passed the house of commons on Feb. 27, 1765, and the house of lords on March 8, and received the royal assent on March 22. This act declared that every document used in trade or legal proceedings, to be valid, must have affixed to it a stamp, the lowest in value costing a shilling, and the duty increasing indefinitely in proportion to the value of the writing. To enforce the act, against which while it was under discussion the colonies had vehemently remonstrated, parliament authorized the ministry to send as many troops as they saw proper to America, for whom the colonies were required to find "quarters, fuel, cider or rum, candles, and other necessaries." These acts created great excitement and indignation in America. The Virginia assembly passed resolutions, introduced by Patrick Henry, declaring that the general assembly of that colony possessed the sole right and power to lay taxes on its inhabitants. The legislature of Massachusetts resolved that the courts should conduct their business without the use of stamps. In New York and Pennsylvania the opposition, though not so general, was yet very strong. Everywhere the people determined not to use the stamps, and associations calling themselves "sons of liberty" were organized in opposition to the act and for the general defence of the rights of the colonies. So powerful were these combinations, and so intense the popular indignation, that when the day came (Nov. 1) on which the obnoxious law was to go into effect, it was found that all the stamp distributors had resigned their offices. Meantime in June the Massachusetts legislature issued a circular inviting all the colonies to send delegates to a congress at New York on the first Tuesday of October. On that day delegates from nine of the colonies appeared. The congress drew up a declaration of rights, a memorial to parliament, and a petition to the king, in which they claimed the right of being taxed only by their own representatives; and these proceedings were approved by the colonial assemblies. The merchants of the principal cities agreed to purchase no more goods in England till the act was repealed, and the people pledged themselves to use no articles of English manufacture. These demonstrations of popular feeling in America led to the repeal of the stamp act on March 18, 1766, an event celebrated with great rejoicings both in the colonies and in the English seaports, whose trade was already seriously affected. But the plan of taxing America was not yet given up, and in June, 1767, parliament passed an act imposing duties on paper, glass, tea, and some other articles imported into the colonies. The colonies in return revived with renewed vigor their non-importation associations. Massachusetts, and especially the town of Boston, was foremost in the opposition; and in Boston, on the occasion of the seizure (June 10, 1768) of a sloop belonging to John Hancock for an alleged false entry, a disturbance occurred, which the commissioners of customs made the pretext for retiring to a vessel of war in the harbor. The government resolved to take vengeance on "the insolent town of Boston," and a military force under Gen. Gage was sent to occupy the place in September. A collision took place March 5, 1770, between the soldiers and a crowd of citizens, in which three of the latter were killed and eight wounded. This "Boston massacre," as it was called, caused great excitement throughout the country, and had much influence in heightening the popular feeling against England. The non-importation associations soon produced such an effect in England, that in April, 1770, the government removed all the duties except that of threepence a pound on tea, which was retained at the express command of George III., who said that "there should be always one tax, at least, to keep up the right of taxing." This did not satisfy the Americans, who objected not to the amount of the taxes, but to the principle of taxation without representation; and combinations were formed against the importation and use of tea, and measures taken to prevent its being either landed or sold. At Boston, on the evening of Dec. 16, 1773, a band of men disguised as Indians went on board three tea ships, which had recently arrived from England and lay at one of the wharves, and, taking out the chests, emptied the tea into the water, and then quietly retired. When the news of this action reached England, the government determined to punish the colonies, and especially to make an example of Boston. Parliament accordingly, in March, 1774, passed the "Boston port bill," which closed that port to all commerce, and transferred the board of customs to Marblehead and the seat of colonial government to Salem. Bills were also passed abrogating the most popular features of the colonial charter, and authorizing the commander to quarter his army in towns, and to transfer to another colony or to Great Britain any persons informed against or indicted for crimes committed in supporting the revenue laws or suppressing riots. These acts excited to a still greater pitch the already deep indignation of the people. Boston was everywhere regarded as the champion of popular rights, and as the victim of ministerial persecution; and money and provisions were sent to it from the most distant colonies and from England. Hutchinson was superseded as governor of Massachusetts in May, 1774, by Gen. Gage. Meanwhile conventions were held and delegates chosen to the congress at Philadelphia, known as the "old continental congress," which met Sept. 5 in Carpenters' hall, all the colonies being represented except Georgia and North Carolina; but delegates from the latter arrived on the 14th. Among the 53 members were Washington, Patrick Henry, Richard Henry Lee, Edward and John Rutledge, Christopher Gadsden, Samuel Adams, John Adams, Roger Sherman, Philip Livingston, William Livingston, and John Jay. Peyton Randolph of Virginia (succeeded by Henry Middleton of South Carolina on Oct. 22) was chosen speaker, and Charles Thomson of Pennsylvania secretary. The discussions were opened on the second day by Patrick Henry in a speech of surpassing eloquence, in which he said: "British oppression has effaced the boundaries of the several colonies; the distinctions between Virginians, Pennsylvanians, New Yorkers, and New Englanders are no more. I am not a Virginian, but an American." A declaration of rights was agreed upon, in which was set forth the claim of the colonists as British subjects to participate in making their own laws and in imposing their own taxes, to the right of trial by a jury of the vicinage, of holding public meetings, and of petitioning for redress of grievances. The maintenance of a standing army in the colonies without their consent was protested against, as were eleven acts passed since the accession of George III. in violation of colonial rights and privileges. The measures of redress which they proposed were peaceable, and comprised the formation of an "American association," pledged not to trade with Great Britain or the West Indies, nor with those engaged in the slave trade, and not to use British goods or tea. Among the papers issued by them were a petition to the king and an address to the people of Canada, written by John Dickinson of Pennsylvania; an address to the people of Great Britain, by John Jay; and a memorial to the people of the colonies, by Richard Henry Lee. The congress adjourned on Oct. 26, after providing for another congress to meet the following May, in case redress of grievances should not meanwhile be obtained. Perceiving a conflict to be almost inevitable, the people of the colonies began to prepare earnestly for war, and in Massachusetts nearly all men able to bear arms were trained daily in military exercises, and engaged to take the field at a moment's notice, whence originated their name of "minute men." Gen. Gage began to fortify Boston neck, and to seize arms and ammunition in the surrounding towns. Small stores of these had been accumulated by the provincial government of Massachusetts at Worcester and at Concord. Gage, on the night of April 18, 1775, secretly despatched a large force to destroy the stores at Concord. The movements of the British were vigilantly watched, and the minute men were roused in every direction. At Lexington, half way between Boston and Concord, on the following morning, the first blood of the revolution was shed. Major Pitcairn ordered the soldiers to fire upon the citizens who appeared in arms upon the common, and eight were killed and nine wounded. The British proceeded to Concord, and destroyed some stores, but met with such resistance at the north bridge over Concord river that they were forced to retreat, and, hotly pursued by the Americans, made their way back to Boston with a loss of 273 killed, wounded, and missing. The entire loss of the Americans during the day was 49 killed, 34 wounded, and 5 missing. This action brought the political contest between the colonies and England to a summary ending, and inaugurated the war of the revolution. The tidings of the fight spread with wonderful rapidity while it was going on, and everywhere throughout New England the people sprang to arms; and on the night of the day following the action the king's governor and army found themselves closely beleaguered in Boston. The provincial congress of Massachusetts on April 22 resolved unanimously that a New England army of 30,000 men should be raised, of which the quota of Massachusetts should be 13,600. As the news from Lexington and Concord spread westward and southward, the people everywhere rose in arms, and before the close of summer the power of all the royal governors from Massachusetts to Georgia was at an end. Volunteer expeditions from Vermont and Connecticut, led by Ethan Allen and Benedict Arnold, seized the important fortresses of Ticonderoga (May 10) and Crown point (May 12), whose cannon and ammunition were of incalculable value to the poorly equipped forces of America. In North Carolina a convention assembled at Charlotte, Mecklenburg co., in May, proclaimed their constituents absolved from all allegiance to the British crown, and organized a local government with preparations for military defence. The second continental congress assembled on May 10 at Philadelphia, in the state house, now known as Independence hall. Among the members were Franklin, Hancock, Samuel Adams, John Adams, Washington, Richard Henry Lee, Patrick Henry, Jay, George Clinton, and Robert R. Livingston. Hancock, who with Samuel Adams had been proscribed as a rebel, was elected president on May 24, Peyton Randolph vacating the chair to attend the Virginia legislature. Conservative and moderate to the last, the congress sent still another petition to the king, denying any intention of separation from England, and asking only for redress of grievances. But they took measures to raise an army, to equip a navy, and to procure arms and ammunition. The forces before Boston were adopted as the continental army, and at the suggestion of the New England members Washington was nominated and unanimously chosen (June 15) as commander-in-chief. Before he could reach the seat of war the battle of Bunker Hill had been fought, June 17. (See Bunker Hill.) Four days later he arrived, and on July 3 assumed command of the army in Cambridge. Charles Lee, Philip Schuyler of New York, Artemas Ward of Massachusetts, and Israel Putnam of Connecticut had been elected major generals. Horatio Gates (adjutant general), Seth Pomeroy, Richard Montgomery, David Wooster, William Heath, Joseph Spencer, John Thomas, John Sullivan, and Nathanael Greene were chosen brigadiers. The army was unorganized, undisciplined, poorly clad, imperfectly armed, and almost destitute of powder. With the aid of Gates, who almost alone of the generals had had much experience in war, Washington brought the troops into tolerable order, and regularly beleaguered Boston till March 17, 1776, when the British evacuated the city and sailed for Halifax, carrying with them a large body of loyalists. Meantime an invasion of Canada, whose inhabitants were reported to be disaffected to British rule, was decided upon by congress, and carried out with insufficient forces under command of Gen. Montgomery. Montreal was taken, and Quebec was attacked Dec. 31, 1775, by parties led by Montgomery and Arnold. The assault was conducted with great courage and energy, but was repulsed, and Montgomery was slain and Arnold severely wounded. After a blockade of the city continued for some months, the Americans, whose forces were totally inadequate in numbers and equipment to the enterprise, on the arrival of powerful reënforcements to the British, abandoned the province in June, 1776. On June 28 a British fleet made an attack on Charleston, S. C., where they were repulsed with great loss by a small force in Fort Sullivan (afterward Fort Moultrie), commanded by Col. Moultrie. In all these operations the Americans were greatly impeded by want of powder and other munitions of war. Cruisers were fitted out by order of congress and by some of the colonies, and several of the British supply ships were captured. Congress also appointed a naval committee with authority to build 13 frigates. A secret committee appointed to correspond privately with the friends of the colonies in Europe may be regarded as the germ of the state department. A financial committee and a war committee had already been instituted, and thus the main departments of the government of the united colonies were put in operation. The success of the colonial armies at Boston and at Charleston, and the outrages committed by British commanders on the coast and in Virginia, greatly stimulated the feeling in favor of independence, which Samuel Adams and a few others had desired from the beginning of the contest; and a powerful impulse was given to this sentiment by Thomas Paine's "Common Sense," which was issued about the beginning of 1776 and widely circulated. On June 7 Richard Henry Lee introduced a resolution into congress declaring "That these united colonies are, and of right ought to be, free and independent states; that they are absolved from all allegiance to the British crown, and that all political connection between them and the state of Great Britain is, and ought to be, totally dissolved." This was adopted on July 2 by the vote of twelve colonies, the delegates from New York, pending the decision of the question by the people of that colony, not voting. On the 4th the Declaration of Independence, written by Jefferson, setting forth the reasons for the separation, was adopted by the same vote, and in this document the colonies were first designated the "United States of America." On the same day it was authenticated by the president and secretary of congress, and published, but it was not then signed by the members. Having been engrossed on parchment, it was signed on Aug. 2 by 54 delegates, and subsequently by two others, 56 in all, representing all the thirteen colonies, the New York convention having approved the act on July 9. The text of the declaration is as follows:

When, in the course of human events, it becomes necessary for one people to dissolve the political bands which have connected them with another, and to assume among the powers of the earth the separate and equal station to which the laws of nature and of nature's God entitle them, a decent respect to the opinions of mankind requires that they should declare the causes which impel them to the separation.

We hold these truths to be self-evident: That all men are created equal; that they are endowed by their Creator with certain unalienable rights; that among these are life, liberty, and the pursuit of happiness. That to secure these rights, governments are instituted among men, deriving their just powers from the consent of the governed; that whenever any form of government becomes destructive of these ends, it is the right of the people to alter or to abolish it, and to institute a new government, laying its foundation on such principles, and organizing its powers in such form, as to them shall seem most likely to effect their safety and happiness. Prudence, indeed, will dictate that governments long established should not be changed for light and transient causes; and accordingly, all experience hath shown that mankind are more disposed to suffer, while evils are sufferable, than to right themselves by abolishing the forms to which they are accustomed. But when a long train of abuses and usurpations, pursuing invariably the same object, evinces a design to reduce them under absolute despotism, it is their right, it is their duty, to throw off such government, and to provide new guards for their future security. Such has been the patient sufferance of these colonies, and such is now the necessity which constrains them to alter their former systems of government. The history of the present king of Great Britain is a history of repeated injuries and usurpations, all having in direct object the establishment of an absolute tyranny over these states. To prove this, let facts be submitted to a candid world:

He has refused his assent to laws the most wholesome and necessary for the public good.

He has forbidden his governors to pass laws of immediate and pressing importance, unless suspended in their operation till his assent should be obtained; and, when so suspended, he has utterly neglected to attend to them.

He has refused to pass other laws for the accommodation of large districts of people, unless those people would relinquish the right of representation in the legislature; a right inestimable to them, and formidable to tyrants only.

He has called together legislative bodies at places unusual, uncomfortable, and distant from the depository of their public records, for the sole purpose of fatiguing them into compliance with his measures.

He has dissolved representative houses repeatedly, for opposing with manly firmness his invasions on the rights of the people.

He has refused, for a long time after such dissolutions, to cause others to be elected; whereby the legislative powers, incapable of annihilation, have returned to the people at large for their exercise; the state remaining, in the mean time, exposed to all the danger of invasion from without and convulsions within.

He has endeavored to prevent the population of these states; for that purpose obstructing the laws for naturalization of foreigners, refusing to pass others to encourage their migration hither, and raising the conditions of new appropriations of lands.

He has obstructed the administration of justice, by refusing his assent to laws for establishing judiciary powers.

He has made judges dependent on his will alone for the tenure of their offices, and the amount and payment of their salaries.

He has erected a multitude of new offices, and sent hither swarms of officers to harass our people and eat out their substance.

He has kept among us, in times of peace, standing armies, without the consent of our legislatures.

He has affected to render the military independent of, and superior to, the civil power.

He has combined with others to subject us to a jurisdiction foreign to our constitution and unacknowledged by our laws, giving his assent to their acts of pretended legislation—

For quartering large bodies of armed troops among us;

For protecting them, by a mock trial, from punishment for any murders which they should commit on the inhabitants of these states;

For cutting off our trade with all parts of the world;

For imposing taxes on us without our consent;

For depriving us, in many cases, of the benefits of trial by jury;

For transporting us beyond seas to be tried for pretended offences;

For abolishing the free system of English laws in a neighboring province, establishing therein an arbitrary government, and enlarging its boundaries, so as to render it at once an example and fit instrument for introducing the same absolute rule into these colonies;

For taking away our charters, abolishing our most valuable laws, and altering, fundamentally, the powers of our governments;

For suspending our own legislatures, and declaring themselves invested with power to legislate for us in all cases whatsoever.

He has abdicated government here, by declaring us out of his protection and waging war against us.

He has plundered our seas, ravaged our coasts, burned our towns, and destroyed the lives of our people.

He is at this time transporting large armies of foreign mercenaries, to complete the works of death, desolation, and tyranny, already begun with circumstances of cruelty and perfidy scarcely paralleled in the most barbarous ages, and totally unworthy the head of a civilized nation.

He has constrained our fellow citizens, taken captive on the high seas, to bear arms against their country, to become the executioners of their friends and brethren, or to fall themselves by their hands.

He has excited domestic insurrections amongst us, and has endeavored to bring on the inhabitants of our frontiers the merciless Indian savages, whose known rule of warfare is an undistinguished destruction of all ages, sexes, and conditions.

In every stage of these oppressions, we have petitioned for redress in the most humble terms. Our repeated petitions have been answered only by repeated injury. A prince,

> whose character is thus marked by every act which may define a tyrant, is unfit to be the ruler of a free people.
>
> Nor have we been wanting in attention to our British brethren. We have warned them, from time to time, of attempts made by their legislature to extend an unwarrantable jurisdiction over us. We have reminded them of the circumstances of our emigration and settlement here. We have appealed to their native justice and magnanimity, and we have conjured them, by the ties of our common kindred, to disavow these usurpations, which would inevitably interrupt our connections and correspondence. They, too, have been deaf to the voice of justice and consanguinity. We must, therefore, acquiesce in the necessity which denounces our separation, and hold them, as we hold the rest of mankind, enemies in war, in peace friends.
>
> We, therefore, the representatives of the United States of America, in general congress assembled, appealing to the Supreme Judge of the world for the rectitude of our intentions, do, in the name and by the authority of the good people of these colonies, solemnly publish and declare that these united colonies are, and of right ought to be, free and independent states; that they are absolved from all allegiance to the British crown, and that all political connection between them and the state of Great Britain is, and ought to be, totally dissolved; and that, as free and independent states, they have full power to levy war, conclude peace, contract alliances, establish commerce, and to do all other acts and things which independent states may of right do. And for the support of this declaration, with a firm reliance on the protection of Divine Providence, we mutually pledge to each other our lives, our fortunes, and our sacred honor.

"The declaration was not only the announcement of the birth of a people," says Bancroft, "but the establishment of a national government; a most imperfect one, it is true, but still a government, in conformity with the limited constituent powers which each colony had conferred upon its delegates in congress. The affairs of internal police and government were carefully retained by each separate state, which could, each for itself, enter upon the career of domestic reforms. But the states, which were henceforth independent of Britain, were not independent of one another; the United States of America assumed powers over war, peace, foreign alliances, and commerce." Soon after the evacuation of Boston by the British, Washington had transferred his army to the city of New York. On June 29 a fleet from Halifax, bearing Gen. Howe and the late garrison of Boston, entered New York harbor, and on July 2 landed the forces on Staten Island. A few days later arrived Admiral Lord Howe, to whom, in conjunction with his brother Sir William, the king had intrusted the control of American affairs. The British government, unable to recruit the army to the desired number from its own people, who disapproved the war, had hired from German princes, and especially from Hesse-Cassel, large bodies of mercenaries; and with these and fresh troops brought from the south by Sir Henry Clinton, the force on Staten Island was augmented to 30,000 men. Washington's army was much less in numbers, and every way inferior in supplies and equipments. The campaign began on Long Island, where on Aug. 27 the Americans were defeated with heavy loss, and forced to abandon that island, and soon after the city of New York. Having fought another unsuccessful battle at White Plains (Oct. 28), Washington early in December was compelled to retreat beyond the Delaware at the head of but 3,000 men, poorly clad, half starved, and destitute of blankets and tents. About the same time the British seized and held the island of Rhode Island, and at Baskingridge, N. J., captured Gen. Charles Lee. On the night of Dec. 25 Washington crossed the Delaware in open boats with 2,400 men, and falling upon the British forces at Trenton captured about 1,000 Hessians. A few days later (Jan. 3, 1777), he defeated the enemy again at Princeton, taking 230 prisoners. Soon after the army went into winter quarters at Morristown. When the campaign opened in the spring of 1777, Washington's force consisted of about 7,500 men. Gen. Howe, after vainly attempting to bring on a general engagement, withdrew his forces (June 30) from New Jersey to Staten Island, and afterward sailed with nearly 20,000 men for the Chesapeake, where he landed on Elk river and threatened Philadelphia. To defend the capital Washington was forced to give battle on the Brandywine, Sept. 11, but was outnumbered and compelled to retreat with the loss of nearly 1,000 men. Lafayette, who had recently entered the service of the United States as a volunteer, and had been made a major general, was severely wounded on this occasion. On the 26th the British took possession of Philadelphia without opposition. On Oct. 4 Washington made an attack on the British at Germantown, seven miles from Philadelphia, but was repulsed with heavy loss; and soon afterward both armies went into winter quarters, the Americans at Valley Forge, on the Schuylkill, 20 m. from Philadelphia. The want of success in this region was more than counterbalanced by victories in the north. A British army, 7,500 strong, besides Indians, commanded by Gen. Burgoyne, advanced from Canada by Lake Champlain, and took Ticonderoga, Fort Independence, and Whitehall. Strong detachments, which were sent to Bennington, Vt., to destroy a collection of stores, were met there (Aug. 16) and defeated with the loss of about 200 killed and 600 prisoners by the Vermont and New Hampshire militia led by Gen. Stark. Burgoyne advanced to Stillwater on the Hudson, where he was encountered by Gen. Gates; and on Sept. 19 an indecisive engagement was fought at that place, in which the British lost more than 600 men. The American encampment had been strongly fortified by Kosciuszko. On Oct. 7 a second battle (commonly called the battle of Saratoga) was fought on nearly the same ground, in which the Americans had the advantage; and ten days later Burgoyne with his whole army capitulated at Saratoga. The consequences of this victory were of the highest importance at home and abroad. On Dec. 1 Baron Steuben, a German officer, arrived in the country, and during the winter joined Washington at Valley Forge. He was afterward appointed inspector general, and was of great service in introducing discipline into the army. From the beginning of the conflict the French government had secretly encouraged the revolt of the colonies, and had furnished them with supplies of arms and military stores, without which it would have been almost impossible to carry on the war. Franklin, Silas Deane, and Arthur Lee had been sent by congress as commissioners to France shortly after the declaration of independence, but received no open countenance from the court till after the surrender of Burgoyne. That event decided the negotiations in their favor; and in February, 1778, treaties of alliance and of amity and commerce were signed at Paris. Sir Henry Clinton, who succeeded Howe as commander-in-chief of the British, evacuated Philadelphia in the night of June 17 with more than 17,000 men, and on the 18th began his march toward New York. Washington pursued, and on the 28th the two armies engaged in battle on the plains of Monmouth, near the village of Freehold, N. J. The action was not decisive, but the Americans remained masters of the field, while the British retreated to New York and remained inactive for the rest of the summer. On July 8 a French fleet from Toulon, under Count d'Estaing, anchored in Delaware bay, but too late to intercept the British squadron and transports retreating from Philadelphia. An attempt made in August with the assistance of the French fleet to drive the British from Rhode Island proved a failure, and d'Estaing, without having accomplished anything of importance, sailed in November for the West Indies. At the close of the campaign of 1778 the position of the British was not at all advanced from that which their forces held in 1776. They occupied nothing but Rhode Island and the island of Manhattan, while the Americans had gained largely in knowledge of the art of war, and had secured the powerful alliance of France. But great embarrassment was felt from the wretched condition of the national finances, the continental money issued by congress having depreciated to a very low point. In this emergency the patriotism and the financial skill and credit of Robert Morris were of the highest value. In 1779 the principal theatre of war was at the south, where Gen. Benjamin Lincoln commanded the Americans. Toward the end of 1778 Gen. Clinton had sent an expedition to Georgia, which defeated the American forces at Savannah, and took possession of the city, Dec. 29; and the colony was soon completely in the power of the British. In September, 1779, Savannah was besieged by a French and American force, and on Oct. 9 an assault was made upon it, which was repulsed with a loss to the allies of nearly 800 men, among them Casimir Pulaski. The siege was thereupon abandoned. About this time the British evacuated Rhode Island, to concentrate their forces at New York. Paul Jones, commanding an American frigate, captured on Sept. 23 two British ships of war in the English channel, in one of the most desperate naval battles ever fought. During the whole war in fact Paul Jones was actively employed against the enemy on the sea, and, together with a swarm of privateers from New England, inflicted immense loss on the mercantile marine of England. One of the most brilliant achievements of the war was the storming (July 16) of Stony Point on the Hudson by Gen. Wayne at the head of 1,200 men, taking 543 prisoners; only 15 of his men were killed, while the British killed numbered 63. About the beginning of 1780 Clinton, leaving the Hessian general Knyphausen in command at New York, sailed south with 8,500 men to carry the war into the Carolinas. Charleston was besieged for several weeks, and Gen. Lincoln after a feeble defence surrendered on May 12, the garrison becoming prisoners of war. The rest of the state of South Carolina was overrun by detachments of the British, and nominally submitted to the restoration of the royal authority, so that Clinton, deeming his conquest complete, sailed for New York on June 5, leaving Lord Cornwallis in command. But a guerilla warfare, under the command of Sumter, Marion, and other partisan leaders, continually harassed not only the British but the tories, as the American royalists were commonly called, of whom there were great numbers in the state. Congress sent Gen. Gates to recover South Carolina. On his first encounter with Cornwallis at Camden, Aug. 16, he was routed with great loss, Baron de Kalb, a French officer of experience, who was second in command, being mortally wounded. Gates with the remnant of his force fled to North Carolina. Within three months two American armies had been destroyed, while the most formidable of the partisan bands, that of Sumter, had been dispersed by Col. Tarleton. Early in September Cornwallis marched into North Carolina, where on Oct. 7, at King's mountain, a detachment from his army was totally defeated by 900 militia, who killed and captured upward of 1,100 of the enemy. This serious reverse, and the renewed activity of Marion, Sumter, and other partisan leaders, induced Cornwallis to withdraw to South Carolina. During the summer the only military operation of importance in the north was an unsuccessful irruption of the British into New Jersey. Soon after, on July 10, a French fleet arrived at Newport, bringing the count de Rochambeau and 6,000 soldiers. Washington went to Hartford in September to confer with the French officers, and during his absence it was discovered that Benedict Arnold, who commanded the important fortress of West Point, had agreed to deliver that stronghold and its dependencies into the hands of Sir Henry Clinton. Arnold escaped, but Major André, the British officer who communicated with him, was caught and hanged as a spy. The principal military operations of 1781 were in the south, where Greene had been made commander in place of Gates. At Cowpens, S. C., on Jan. 17, Gen. Morgan won a brilliant victory over the British under Col. Tarleton. On March 15, at Guilford Court House, N. C., a battle was fought in which the British gained the victory, but drew from it no advantage; and on Sept. 8 occurred the drawn battle of Eutaw Springs, a bloody action which nearly terminated the war in South Carolina. At the close of the year the British in the states south of Virginia were confined to Charleston and Savannah. Cornwallis, having advanced into Virginia in April, was opposed by Lafayette, Wayne, and Steuben, and fortified himself at Yorktown, where he gathered a considerable army. Meanwhile the American army under Washington and the French army of Rochambeau had formed a junction on the Hudson; and while the British commander, Sir Henry Clinton, was kept from sending aid to Cornwallis by apprehensions that New York was threatened, the allied army was far on its way toward Yorktown, where it arrived Sept. 28, 1781, and began a regular siege, which lasted till Oct. 19, when Cornwallis surrendered with his whole force of 7,247 men, besides 840 sailors; 106 guns were taken. This victory substantially terminated the contest, and secured the independence of America. The French contributed 37 ships (under De Grasse) and 7,000 men to the besieging force, and the Americans 9,000 men. In England Lord North and his administration were forced to retire, March 20, 1782, and were succeeded by a cabinet opposed to the further prosecution of the war, headed by the marquis of Rockingham. Orders were sent to the British commanders in America to cease hostilities, and in July, 1782, Savannah was evacuated, and Charleston on Dec. 14. Adams, Franklin, Jay, and Laurens on the part of the United States, and Strachey, Oswald, and Fitzherbert on the part of Great Britain, signed a preliminary treaty of peace at Paris on Nov. 30, 1782; and on Sept. 3, 1783, a definitive treaty was signed at Versailles, by which the United States were formally acknowledged by Great Britain to be free, sovereign, and independent. New York, the last position held by the British on our coast, was evacuated Nov. 25, 1783. In the seven years of the revolutionary war Great Britain sent to America about 112,000 soldiers and 22,000 seamen. The forces raised by the United States during the same period consisted of about 232,000 continental soldiers and 56,000 militia. On Nov. 2 Washington issued a farewell address to the armies of the United States, and, after taking leave on Dec. 4 of his officers at New York, proceeded to Annapolis, Md., where congress was then in session, and on Dec. 23 resigned his commission as commander-in-chief and retired to his estate at Mount Vernon.—The existence of the United States as a political entity may be dated from the assembling of the second continental congress, May 10, 1775, as the first assumed no political powers. From that date to March 1, 1781, when the articles of confederation were finally ratified, the government of the Union was revolutionary, the powers exercised by congress being assumed by that body and conceded by the states from the necessity of the situation. The period of the confederation extended to March 4, 1789, when the constitution went into effect. On June 12, 1776, while the resolution of independence was under consideration in congress, a committee of one from each colony was created to draft a form of confederation, and the articles reported by it were adopted, Nov. 15, 1777. They were ratified by South Carolina on Feb. 5, 1778, and by ten other states before the close of that year. Delaware ratified them on Feb. 1, 1779, and Maryland on Jan. 30, 1781; and, being signed by delegates from all the states, they went into effect as above stated. The delay of Maryland was caused by her refusal to join the confederation until those states claiming territory beyond their settled limits should cede it to the Union for the common benefit. Cessions having been made, an ordinance was passed by congress, July 13, 1787, for the government of the territory N. W. of the Ohio river, since famous as the ordinance of 1787. Dissatisfaction with the confederation, owing to the weakness of the central government under it, soon became widespread, and in September, 1786, a convention of delegates from several states at Annapolis, Md., recommended the calling of a convention of delegates from all the states to propose changes in the articles of confederation. This plan was approved by congress on Feb. 21, 1787, and the convention organized at Philadelphia on May 25, by the choice of Washington as president. It remained in session in Carpenters' hall until Sept. 17, when it adjourned after adopting the constitution. All the states were represented except Rhode Island. On the 28th congress passed a resolution transmitting the constitution to the several states to be acted upon by conventions. Delaware ratified it on Dec. 7, and ten other states prior to Sept. 13, 1788, when a resolution of congress declared it ratified by nine states (the constitution providing that when ratified by that number it should go into effect in the states ratifying), fixed the first Wednesday of January, 1789, for the choice of presidential electors in the several states, and the first Wednesday of February for the choice of president by the electors, and provided that the new government should go into operation on the first Wednesday of March. The second continental congress expired on March 4, 1789, having maintained its corporate identity for nearly 14 years, though changed from time to time in its membership. Its presidents, though without power or patronage, were regarded as the personal representatives of the sovereignty of the Union. The following are their names, with the date of their election: Peyton Randolph of Virginia, May 10, 1775; John Hancock of Massachusetts, May 24, 1775;

Henry Laurens of South Carolina, Nov. 1, 1777; John Jay of New York, Dec. 10, 1778; Samuel Huntington of Connecticut, Sept. 28, 1779; Thomas McKean of Delaware, July 10, 1781; John Hanson of Maryland, Nov. 5, 1781; Elias Boudinot of New Jersey, Nov. 4, 1782; Thomas Mifflin of Pennsylvania, Nov. 3, 1783; Richard Henry Lee of Virginia, Nov. 30, 1784; Nathaniel Gorham of Massachusetts, June 6, 1786; Arthur St. Clair of Pennsylvania, Feb. 2, 1787; Cyrus Griffin of Virginia, Jan. 22, 1788. The first congress under the constitution was long without a quorum; the house did not organize till March 30, 1789, nor the senate till April 6. The electoral votes were then counted, when Washington, having received the entire number (69), was declared elected president, and John Adams, who had received the next highest number (34), was declared elected vice president. Adams took his seat as president of the senate on April 21, and Washington was inaugurated in New York on April 30. The president appointed Jefferson secretary of state, Hamilton secretary of the treasury, Henry Knox of Massachusetts secretary of war, and Edmund Randolph of Virginia attorney general, those officers then constituting the whole of the cabinet. North Carolina ratified the constitution on Nov. 21, 1789, and Rhode Island on May 29, 1790, completing the list of the original states. Ten amendments in the nature of a bill of rights, suggested by the conventions in some of the states, and adopted by the first congress, became a part of the constitution in 1791. An eleventh amendment, taking from the federal courts jurisdiction of actions prosecuted against a state by citizens of another state, became operative in 1798, and a twelfth, changing the method of electing the president and vice president, in 1804. No further amendments were made for more than 60 years. The seat of government was removed to Washington in 1800, the first session of congress held there commencing on Nov. 17. The previous seats of government were as follows, the dates being those of the opening of sessions of congress: Philadelphia, May 10, 1775; Baltimore, Dec. 20, 1776; Philadelphia, March 4, 1777; Lancaster, Pa., Sept. 27, 1777; York, Pa., Sept. 30, 1777; Philadelphia, July 2, 1778; Princeton, N. J., June 30, 1783; Annapolis, Md., Nov. 26, 1783; Trenton, N. J., Nov. 1, 1784; New York, Jan. 11, 1785, where the constitutional government was organized in 1789; and Philadelphia, Dec. 6, 1790. The beneficial influence of the new government was immediately felt in the restoration of public confidence, the revival of commerce, and the general prosperity of the country. A system of finance, advocated in an able report by Hamilton, was adopted, and the debts of the late confederacy and of the individual states were assumed by the general government. A bank of the United States was incorporated in 1791, and a mint was established at Philadelphia in 1792. In the summer of 1790 an Indian war broke out with the tribes of the northwest, who, after inflicting defeats on Gens. Harmar and St. Clair, were finally quelled by Gen. Wayne, and peace was restored in August, 1795. The great revolution in France, which broke out at the beginning of Washington's administration, was powerfully felt in its principles and effects in this country. Two parties had already been formed: the federalists, composed of those who favored the maintenance of the constitution just as it was; and the republicans or democrats, who desired to introduce amendments to limit the federal power, and to increase that of the states and the people. Washington, Adams, Hamilton, and Jay were accounted among the federalists; while Jefferson, Madison, Gallatin, and Edward Livingston were among the leaders of the republicans. The federal party on the French question advocated a strict neutrality, while the republicans freely avowed their sympathy for France, and their willingness to aid the French republic in its struggle with the European monarchies. Party spirit ran high on this point, yet at the second presidential election in 1792 Washington again received the unanimous votes (132) of the electoral colleges. Adams was reelected vice president, receiving 77 votes, while George Clinton, the republican candidate, received 50 votes, and 5 were cast for others. The feeling against Great Britain existing since the revolution was strongly stimulated by the obnoxious conduct of the British government in retaining possession of forts in the west to which its title had been ceded by the treaty of 1783, and in seizing American vessels and impressing American seamen. After in vain remonstrating against these outrages, the president sent John Jay as a special envoy to England, where, in November, 1794, a treaty was concluded, which was regarded by the republicans as so favorable to England that the requisite confirmation by the senate was obtained with difficulty, and its promulgation among the people raised an extraordinary clamor against Jay and the president, which however soon subsided. In pursuance of this treaty the forts were surrendered in 1796. Its ratification exasperated the French government, which openly showed its displeasure by decrees under which American commerce suffered continual annoyances and losses. Among the important domestic events of Washington's administration were the admission into the Union of the new states of Vermont (1791), Kentucky (1792), and Tennessee (1796), and the whiskey insurrection against an unpopular excise law, which in 1794 threw western Pennsylvania into confusion, but was energetically suppressed by the president, who called out 15,000 militia. On the approach of the third presidential election, Washington positively declined to be a candidate, and the two great parties at once arrayed themselves against each other with a bitterness of zeal never since equalled. The federalists supported John Adams and the republicans Thomas Jefferson. Adams, who received 71 electoral votes, was chosen president, while Jefferson, who received 68, the next highest number, became, by the constitution as it then was, the vice president. The two next highest candidates were Thomas Pinckney and Aaron Burr. Timothy Pickering was made secretary of state, Oliver Wolcott of the treasury, James McHenry of war, and Charles Lee attorney general. In 1798 the navy department was created, and Benjamin Stoddert made secretary. The relations between France and the United States were so threatening that one of the first acts of President Adams was to convene congress in extra session, May 13, 1797. Three envoys, C. C. Pinckney, Elbridge Gerry, and John Marshall, were sent to France with authority to adjust all difficulties. The French government refused to receive them, but intimated that a considerable present of money would greatly facilitate negotiations, and that a refusal to pay the bribe would lead to war. "War be it then," replied Pinckney; "millions for defence, but not a cent for tribute." Pinckney and Marshall, who were federalists, were ordered to quit France; but Gerry, who was a republican, was allowed to remain. The insult to their envoys excited great indignation in the United States, and congress made preparations for war. The army and navy were enlarged, and Washington was appointed commander-in-chief, with the rank of lieutenant general. The frigate Constellation captured a French frigate in the West Indies, and disabled another of superior force in an action lasting five hours. The decided measures adopted by the United States were not without effect on the French government, and overtures were made to the president for a renewal of negotiations. A fresh embassy was sent, and, Napoleon Bonaparte having attained to power, a treaty was promptly concluded, Sept. 30, 1800. During these troubles with France two acts were passed by congress, known as the alien and sedition laws: the first, which was limited to two years, empowering the president to order aliens who were conspiring against the peace of the United States to quit the country; the other, which was to remain in force till March 4, 1801, providing among other things for the punishment by fine and imprisonment of seditious libels upon the government. The alien law was defended on the ground that the country swarmed with French and English emissaries, whose mission was to embroil the United States with European quarrels; while the apology for the sedition law was the unquestionable licentiousness of the press, which at that time was chiefly conducted by refugees and adventurers from Great Britain and Ireland. Nevertheless these laws became exceedingly unpopular, and were bitterly denounced as harsh and unconstitutional. They contributed largely to the dissatisfaction with Mr. Adams's administration, which prevailed especially in the south and west, and which led in the next presidential election to the success of the republican candidates, Jefferson and Burr, each of whom received 73 votes, while Mr. Adams received 65, C. C. Pinckney 64, and Jay 1. The tie in the votes for Jefferson and Burr threw the election into the house of representatives, where on the 36th ballot Jefferson was chosen president and Burr vice president. This contest led to the adoption of the twelfth amendment of the constitution, requiring the electors to designate which person is voted for as president and which as vice president, while the original article required them to vote for two persons, of whom the one who had the highest number of votes was to be president, and the next highest vice president. Jefferson's cabinet consisted of James Madison, secretary of state; Samuel Dexter, and afterward Albert Gallatin, of the treasury; Henry Dearborn, of war; Benjamin Stoddert, and afterward Robert Smith, of the navy; and Levi Lincoln, attorney general. For the most part his administration was marked by vigor and enlightened views, and in 1804 he was reelected for a second term, receiving 162 votes. George Clinton was elected vice president by the same vote. The opposition ticket, C. C. Pinckney of South Carolina and Rufus King of New York, received only 14 votes, those of Connecticut and Delaware and 2 from Maryland. During his first term Ohio was admitted (1802), and Louisiana was purchased of France in 1803. The insolence of the piratical states on the Barbary coast was humbled by the bombardment of Tripoli in 1804, and by the invasion of that state by a small force led from Egypt by Capt. Eaton, an American officer, which led to a satisfactory treaty in 1805. In 1806 Aaron Burr secretly organized, chiefly in the western states, a military expedition, which led to his arrest and trial at Richmond in 1807 on a charge of attempting to dismember the Union and to establish an independent dominion west of the Alleghanies; but no overt act being proved against him, he was acquitted. The amicable relations which had existed between the United States and Great Britain for several years began in the latter part of 1805 to be disturbed by the condemnation by British courts of several American vessels for alleged violations of neutrality; and the situation was aggravated by the operation of an order in council (May 16, 1806) of the British government declaring the whole coast of Europe, from the Elbe to Brest, to be in a state of blockade; an order which Napoleon retaliated by declaring in a decree issued at Berlin, Nov. 21, 1806, a blockade of all the ports of the British islands. Under these and other orders and decrees great numbers of American vessels were seized by French and English cruisers, and our foreign commerce, which had attained extraordinary prosperity from the neutral position of the country, was nearly destroyed. The irritation against Great Britain produced by her depredations on our commerce was greatly increased by her persistent assertion of the right to search American vessels for suspected deserters from her navy, a right continually exercised by her cruisers in the most offensive manner, and in the practice of which multitudes of native-born American seamen were forced into the British navy. The insolence of the British naval officers was at length carried so far that in June, 1807, the frigate Chesapeake was stopped near the entrance to Chesapeake bay by the English man-of-war Leopard, and on the refusal of her commander to submit to a search was fired into, and 21 of her crew were killed or wounded. This outrage, for which immediate reparation was demanded by Jefferson, was not atoned for till four years later, and even then the right of search was still claimed by the British government, and eventually became a cause of war. In February, 1806, an act had been passed prohibiting the importation of certain articles of British production, the first of a series of similar measures designed to bring Great Britain to terms. In December, 1807, congress, on the recommendation of the president, laid an embargo, which prohibited the departure from American ports of vessels bound for foreign countries. This measure was vehemently denounced by the federal party, and for a time it prostrated the shipping and commercial interests of the United States. It was repealed in February, 1809, just before the expiration of the president's second term. In the presidential election of 1808 the republican (or, as it was now often called, the democratic) party supported James Madison for president and George Clinton for vice president. Madison and Clinton were elected, the former receiving 122 votes and the latter 113, while the federal candidates, C. C. Pinckney and Rufus King, received each 47, a few votes being cast for other candidates. The ruinous operation of the embargo law had considerably weakened the democratic party, particularly in the commercial eastern and middle states. Mr. Madison formed his cabinet as follows: Robert Smith, secretary of state; Albert Gallatin, of the treasury; William Eustis, of war; Paul Hamilton, of the navy; and Cæsar A. Rodney, attorney general. Congress met in May, 1809, in extra session, and continued the non-importation system. A long negotiation was carried on with the English government on this subject, the orders in council, and the right of search, which resulted only in augmenting the unfriendly feeling between the two countries. Though the president was exceedingly averse to forcible measures, the pressure of public opinion, and the influence of Clay, Calhoun, Lowndes, and other leaders of the war party, at length induced him to acquiesce reluctantly in a declaration of hostilities. He sent to congress, June 1, 1812, a message on the subject of the aggressions of Great Britain, which was referred to the committee on foreign relations in the house of representatives, who on June 3 reported a manifesto as a basis of the declaration of war, for these reasons: the impressment of American seamen by the commanders of British ships of war; the British doctrine and system of blockade; the orders in council; and, lastly, various depredations committed by British subjects on the commerce of the United States. The house adopted the measure by a vote of 79 to 49, and the senate by a vote of 19 to 13; and on June 18 the president signed the act declaring war. For several months thereafter the British government did little toward counter hostilities. But although the United States had the advantage that the main force of their enemy was occupied by the great European conflict, their own preparation for the contest was in every respect inadequate. The treasury was almost empty, the revenue having been nearly ruined by the non-importation acts and embargoes; the army at first numbered but 10,000 men, half of them raw recruits, and was very deficient in officers of experience; while the navy comprised only eight frigates, two sloops, and five brigs. Long before war was declared British emissaries, as was alleged, had been engaged in exciting the northwestern Indians against the Americans; and in the summer of 1811 hostilities were actually begun by the tribes north of the Ohio under the lead of Tecumseh. William Henry Harrison, governor of Indiana territory, encountered them with a considerable force on the banks of the Tippecanoe river, Nov. 7, 1811, and defeated them. After the declaration of war, Gen. Hull, then governor of Michigan territory, was ordered to invade Canada from Detroit, which he accordingly did at the head of 1,800 men. His force was wholly inadequate to the enterprise, and he was soon compelled to fall back; and his men being reduced by various casualties to 800, on Aug. 16, 1812, he surrendered his army, Detroit, and all Michigan to Gen. Brock. An invasion of Canada on the Niagara frontier was almost equally unsuccessful, and the campaign of 1812 closed with little or no credit to the American arms on land. But the navy, small as it was, had achieved a series of brilliant victories. The frigate Constitution, Capt. Isaac Hull, captured the British frigate Guerriere, Aug. 19; the sloop of war Wasp, Capt. Jones, captured the brig Frolic, Oct. 18; the frigate United States, Capt. Decatur, captured the frigate Macedonian, Oct. 25; and the Constitution, of which Capt. Bainbridge had now taken command, captured the frigate Java, Dec. 29. In these contests the British loss in killed and wounded was vastly in excess of that of the Americans, and the result highly elated the public, with whom the navy hitherto had been in no special favor. A swarm of privateers scoured the ocean, preying upon British commerce to such an extent that their captures in this year alone amounted to more than 300 vessels. The campaign of 1813 was marked by alternate successes and reverses. In January a detachment of 900 men from the western army, under Gen. Winchester, was defeated and captured at the river Raisin, and many of the prisoners massacred by the Indian allies of the English. In April Gen. Pike with 1,600 Americans captured York (now Toronto), which was defended by 800 men, but was himself killed by the explosion of a magazine, by which 200 of his men were killed or wounded. In May an attack on Sackett's Harbor by the British under Gen. Prevost was repulsed by Gen. Brown, and Fort George in Canada was taken by the Americans. In October Gen. Harrison defeated the British, who had abandoned Detroit, near the Thames river in Canada, with severe loss, the Indian chief Tecumseh being among the slain. Attempts at an invasion of Canada from Lakes Ontario and Champlain, with a view to the capture of Montreal, came to nothing, partly through disagreement between Gens. Wilkinson and Hampton. The navy as usual was more successful than the army. On Lake Erie, Sept. 10, a British fleet of six vessels was captured after a severe contest by Commodore O. H. Perry, which rendered the Americans masters of the lake. On the ocean, the Hornet, Capt. Lawrence, captured the Peacock, Feb. 24; and the Enterprise, Lieut. Burroughs, captured the Boxer, Sept. 5. On the other hand, the frigate Chesapeake, commanded by Capt. Lawrence, was on June 1 captured by the British frigate Shannon, Capt. Broke. The campaign of 1814 was conducted with more vigor on both sides, and was marked by obstinate and sanguinary engagements on the Niagara frontier. On July 5 the British were defeated at Chippewa by Gen. Brown, and on the 25th at Bridgewater or Lundy's Lane by Gens. Brown and Winfield Scott, the latter of whom had also distinguished himself at Chippewa. The war in Europe having closed, large reënforcements, consisting of troops who had served under Wellington in Spain, were sent to Canada by the British government; and Sir George Prevost, at the head of 12,000 men, invaded New York on the northern frontier and laid siege to Plattsburgh, defended by Gen. Macomb. The army was supported by a powerful fleet on Lake Champlain, commanded by Commodore Downie. On Sept. 11 the United States fleet, under Commodore Macdonough, totally defeated the English fleet, and on the same day the British army retreated in disorder to Canada. In August a British fleet arrived in the Chesapeake with an army of 5,000 men commanded by Gen. Ross, who landed in the Patuxent and marched on Washington, and, after putting to flight the militia at Bladensburg, took possession of the federal city on the 24th, and burned the capitol, the president's house, and other public buildings. On the day after this barbarous exploit the British retired to their ships, and on Sept. 12–13 made an attack on Baltimore, where they were repulsed by the citizens, and Gen. Ross was killed. On the ocean during this year and the beginning of 1815 the British vessels of war Epervier, Avon, Reindeer, Cyane, Levant, Penguin, and Nautilus were taken by the Americans, who on their part lost the frigates Essex and President, both captured by greatly superior forces, besides two or three smaller vessels. After protracted negotiations a treaty of peace was signed at Ghent, Dec. 24, 1814, on the part of the United States, by Henry Clay, John Quincy Adams, Jonathan Russell, James A. Bayard, and Albert Gallatin. The treaty provided for the mutual restoration of all territory taken during the war, and for the mutual appointment of commissioners to determine the northern boundary of the United States. Nothing was said of the impressment of American seamen, one of the main causes of the war, but the practice was discontinued. Before the news of peace could cross the Atlantic, a British army 12,000 strong, led by Gens. Pakenham, Gibbs, Keene, and Lambert, landed on the coast of Louisiana and made an attack on New Orleans, which was defended by Gen. Andrew Jackson with less than 5,000 men, chiefly militia from Tennessee and Kentucky. The attack was repelled, Jan. 8, 1815, with a loss to the British of 2,000 killed, wounded, and prisoners, while the Americans lost only a few men. The war from its beginning had been distasteful to the majority of the people of New England, who, being mostly federalists, regarded it not only as unnecessary and impolitic, but as waged chiefly to gratify democratic prejudice against England and partiality for France. They suffered from it immense losses by the destruction of their commerce and their fisheries, and the federal government did little or nothing for their protection from the enemy. To remedy these evils the celebrated Hartford convention was held. (See HARTFORD CONVENTION.) For many years the democrats continued to impute treasonable designs to that convention, and it was one of the causes which led to the decay and extinction of the federal party. In the latter part of 1813 and the beginning of 1814 the country of the Creek Indians, within the present limits of Alabama, was invaded by four columns, one under Gen. Jackson, and that tribe was severely defeated and compelled to cede the greater part of its lands. During the war the Algerines had resumed their old practice of piracy, had seized several American vessels, and had insulted and plundered the American consul. Immediately after the conclusion of peace with Great Britain a naval force commanded by Decatur was sent to the Mediterranean, which captured several Algerine cruisers, and in a few weeks compelled the rulers of Algiers, Tunis, and Tripoli to make indemnity for their outrages, and to agree to abstain from depredations on American commerce

The national finances were in a very confused state at the close of the war, the debt created by which exceeded $80,000,000. The banks, except in New England, had suspended specie payments, and the want of a uniform and solvent currency was urgently felt. To remedy this latter evil, congress in 1816 chartered for 20 years a national bank at Philadelphia, with a capital of $35,000,000, whose notes furnished a convenient and uniform circulating medium, convertible at all times into gold and silver.—The presidential election of 1812 had resulted in the choice of Mr. Madison for a second term by a vote of 128, against 89 for De Witt Clinton, who was supported by the federalists. Elbridge Gerry was chosen vice president by 131 votes to 86 for Jared Ingersoll. On the approach of the presidential election of 1816, James Monroe of Virginia, Mr. Madison's secretary of state, received the democratic nomination, and in the election was chosen by 183 votes, against 34 votes given to Rufus King by the federal states of Massachusetts, Connecticut, and Delaware. Daniel D. Tompkins of New York was elected vice president. The administration of Mr. Madison terminated March 4, 1817. The war with Great Britain was its principal feature, but among other events of importance were the admission of Louisiana into the Union in 1812, and of Indiana in 1816. President Monroe's cabinet was constituted as follows: J. Q. Adams, secretary of state; William H. Crawford, of the treasury; John C. Calhoun, of war; Benjamin W. Crowninshield, of the navy; and William Wirt, attorney general. His administration commenced under very favorable circumstances. Party distinctions had so nearly disappeared, that democrats and federalists combined to support the government. Monroe was reëlected in 1820 by all the electoral votes except one. Daniel D. Tompkins was reëlected vice president by nearly the same vote. In the spring of 1818 Gen. Jackson led a force against the Seminole Indians in Florida, and destroyed several of their villages. The main event of Monroe's administration was the Missouri controversy, by which for the first time the country was divided upon the slavery question. The admissions to the Union hitherto had been of slaveholding and non-slaveholding states in compensating order. Vermont and Kentucky, Tennessee and Ohio, Louisiana and Indiana had offset each other; and in 1817 the slaveholding state of Mississippi was admitted, followed immediately in 1818 by non-slaveholding Illinois. Congress in its session of 1818-'19 authorized the territory of Alabama, which was rapidly filling with a slaveholding population, to form a constitution without any prohibition of slavery. A similar bill was brought forward for the territory of Missouri, and James Tallmadge of New York moved in the house of representatives to insert a clause prohibiting any further introduction of slaves, and granting freedom to the children of those already there on their attaining the age of 25; and this motion was carried by a vote of 87 to 76. A few days later John W. Taylor of New York moved as an amendment to a bill for the organization of the territory of Arkansas, that slavery should not thereafter be introduced into any part of the territories ceded by France to the United States N. of lat. 36° 30′. This was intended as a compromise, but was warmly opposed, a large number both of northern and southern members declaring themselves hostile to any compromise whatever, and the amendment was consequently withdrawn. The slaveholders contended that for congress to prohibit slavery in the territories would be a violation of the constitutional right of the citizen to enjoy his property anywhere within the jurisdiction of the United States. The restrictionists, on the other hand, denied that men could be property under the jurisdiction of the United States, however the case might be under the laws of particular states; and they maintained that the constitutional question was conclusively settled by the action of the congress contemporaneous with the framing of the federal constitution, which in 1787 introduced into the bill for the government of the territory N. W. of the Ohio the proviso that "there shall be neither slavery nor involuntary servitude in said territory, otherwise than in punishment for crime." And in further confirmation of their views, they brought forward the fact that the most distinguished statesman of the south, Thomas Jefferson, had in 1784 introduced and urged with all his influence the passing of a bill in congress prohibiting slavery not only in all the territory held by the United States, but in all that might be afterward acquired. The debate on this subject was long and excited. The southern orators declared that if the restriction should be persisted in the south would retire and the Union be dissolved. The senate refused to concur in the restriction imposed by the house, and consequently the Missouri bill failed for the session of 1818-'19. During the recess of congress a strong public agitation against slavery arose in the middle states, and finally spread to New England, both democrats and federalists coöperating in it. Alabama was admitted into the Union early in the session of 1819-'20, an event promptly followed by the admission of Maine. When the legislatures of the free states met in their annual session in 1820, the agitation among the people on the slavery question was forcibly expressed by their representatives. Pennsylvania led off by a solemn appeal to the states "to refuse to covenant with crime," and by a unanimous declaration that it was the right and the duty of congress to prohibit slavery in the territories. The rest of the middle states also unanimously adopted similar resolutions. Ohio and Indiana took the same position; and though the New England legislatures were silent, numerous memorials from towns, cities, and public meetings there in favor of freedom were laid before congress. The legislatures of the slave states expressed themselves, on the other hand, very strongly in opposition to restriction. In congress the debate was long and acrimonious. The senate sent to the house the Missouri bill with the prohibition of slavery in that state struck out, but with the proviso that it should not thereafter be tolerated N. of lat. 36° 30′. The striking out of the restrictive clause was reluctantly assented to by the house by a vote of 90 to 87, a very few northern members voting for it. The compromise by which slavery was prohibited for ever N. of 36° 30′ was then agreed to by a vote of 134 to 42. The northern states acquiesced in this compromise as a political necessity, and as finally settling a controversy dangerous to the peace and stability of the Union, and the slavery agitation subsided for a time. Missouri was finally admitted as a state in 1821. The other great question of Mr. Monroe's administration was the recognition of the Spanish American republics, which had declared and maintained their independence for several years. Chiefly by the efforts and the eloquence of Henry Clay, their independence was acknowledged in 1822; and in the following year the president in his annual message put forth a declaration which has since been famous as the "Monroe doctrine." In this it was announced that any attempt on the part of European governments to extend their system to any portion of this hemisphere would be considered dangerous to the peace and safety of the United States; that the republic would not interfere with existing colonies or dependencies, but would regard as the manifestation of an unfriendly disposition to the United States any attempt of a European power to oppress or control the destiny of the governments whose independence the United States had acknowledged. In 1819 Florida had been ceded by Spain.—In the presidential election of 1824 the confused state of parties led to the nomination of four candidates, none of whom had a majority of the electoral votes. Andrew Jackson received 99, John Quincy Adams 84, William H. Crawford 41, and Henry Clay 37. The election went to the house of representatives (the choice being between the three highest candidates), where Mr. Adams received the vote of 13 states, and was declared president; while Jackson received the vote of 7 and Crawford of 4 states. John C. Calhoun had been elected vice president by the electoral colleges, receiving 182 votes to 78 for all others. The total popular vote (the electors in six states being chosen by the legislature) was 352,062, viz.: 155,872 for Jackson, 105,321 for Adams, 46,587 for Clay, and 44,282 for Crawford. The political views of Mr. Adams did not differ from those of Mr. Monroe, and his foreign and domestic policy was very similar. He appointed Henry Clay secretary of state, Richard Rush of the treasury, James Barbour of war, Samuel L. Southard of the navy, and William Wirt attorney general. His administration was remarkable for order, method, and economy, though party spirit was higher than it had been for many years. Perhaps the most important event in his term was the adoption of what was called the American system of protecting home manufactures by a heavy duty upon foreign articles of the same kind, a system popular in the manufacturing north, but bitterly opposed in portions of the agricultural south. A tariff law enacted in 1828 on the principle of protection led a few years later to serious political complications. The presidential contest of the same year was carried on with great animation and virulence, chiefly by means of discussions on the personal character and history of the candidates, Gen. Jackson having been nominated in opposition to Mr. Adams. The result was the election of Jackson by 178 votes to 83 for Adams, while John C. Calhoun was reëlected vice president in opposition to Richard Rush. The popular vote was 647,231 for Jackson and 509,097 for Adams. President Jackson selected for his cabinet Martin Van Buren, secretary of state; Samuel D. Ingham, of the treasury; John H. Eaton, of war; John Branch, of the navy; John McPherson Berrien, attorney general; and William T. Barry, postmaster general. The last named officer was now for the first time made a member of the cabinet. In his first annual message, December, 1829, the president took strong ground against the renewal of the charter of the United States bank, as an institution not authorized by the constitution. A long and excited contest ensued in congress and among the people on this question. Congress in 1832 passed a bill to recharter the bank, but Jackson vetoed it; and as it failed to receive the votes of two thirds of the members of both houses, the bank charter expired by limitation in 1836. The commercial part of the community in this contest generally took the side of the bank, and the party formed in opposition to the president assumed the name of whig, while his supporters adhered to the old name of democrats. The tariff of 1828 had always been distasteful to the cotton-growing states, and on the passing of an act of congress in the spring of 1832 imposing additional duties upon foreign goods, the discontent of South Carolina broke out in almost actual rebellion. A state convention held there in November declared the tariff acts unconstitutional and therefore null and void, and proclaimed that any attempt by the general government to collect duties in the port of Charleston would be resisted by force of arms, and would produce the secession of South Carolina from the Union. The chief leaders of the nullifiers, as this South Carolina party was called, from their assertion of the right of a state to nullify an act of congress which she deemed unconstitutional, were John C. Calhoun, who had resigned the vice presidency and become a senator of the United States;

Robert Y. Hayne, also a senator; and George McDuffie, governor of the state. The nullifiers made considerable military preparations, and for a time civil war between South Carolina and the federal government seemed inevitable. Jackson had just been reëlected for a second term by 219 electoral votes, against a divided opposition which cast 49 votes for Henry Clay, 11 for John Floyd, and 7 for William Wirt, while Mr. Van Buren was chosen vice president. The popular vote was 687,502 for Jackson and 530,189 for his opponents. All the disposable army was ordered to assemble at Charleston under Gen. Scott, and a ship of war was sent to that port to insure the collection of duties. A proclamation was issued, Dec. 10, 1832, denying the right of a state to nullify any act of the federal government, and warning all engaged in fomenting the rebellion that the laws against treason would be enforced at all hazards and to their utmost penalties. The leaders of the nullifiers were also privately given to understand that if they committed any overt act they should surely be hanged. The firmness of the president, who in this conjuncture was warmly supported by the great mass of the nation of all parties, gave an effectual check to the incipient rebellion, and the affair was finally settled by a proposition brought forward in congress by Henry Clay, the leading champion of the protective system, for the modification of the tariff by a gradual reduction of the obnoxious duties; a compromise which was accepted by the nullifiers as the only means of escape from the perilous position in which they had placed themselves. Meanwhile the president's vehemence in party matters had led to sweeping removals from office, and a personal quarrel to changes in the cabinet, which in the latter part of 1831 was constituted thus: Edward Livingston, secretary of state; Louis McLane, of the treasury; Lewis Cass, of war; Levi Woodbury, of the navy; and Roger B. Taney, attorney general. Barry remained postmaster general. In his annual message in December, 1832, the president recommended the removal of the public funds from the bank of the United States, where they were by law deposited. Congress by a decisive vote refused to authorize the removal, and the president on his own responsibility directed the secretary of the treasury to withdraw the deposits and place them in certain state banks. That officer refusing, he was removed, and Mr. Taney, the attorney general, appointed in his place, who complied with the order. This step was attended by a financial panic, and great commercial distress immediately ensued. A resolution censuring the president was passed in the senate, but the house of representatives sustained him. The foreign policy of President Jackson was very successful. Useful commercial treaties were made with several countries, and indemnities for spoliations on American commerce were obtained from France, Spain, Naples, and Portugal. At home the principal events of his administration, besides those already mentioned, were the extinction of the national debt, the beginning, toward the close of 1835, of the war with the Seminole Indians in Florida, and the admission of Arkansas (1836) and Michigan (1837) into the Union.—In the presidential contest of 1836 Mr. Van Buren, who was supported by the democrats, received 170 electoral votes, and was elected; while the opposition or whig vote was divided between William Henry Harrison (73), Hugh L. White (26), Daniel Webster (14), and Willie P. Mangum (11). No candidate having been elected vice president, Richard M. Johnson, who had received the highest number of votes (147, against 77 for Francis Granger, 47 for John Tyler, and 23 for William Smith), was chosen by the senate. The popular vote was 761,549 for Van Buren and 736,656 for the opposition candidates. President Van Buren selected as his cabinet, John Forsyth, secretary of state; Levi Woodbury, of the treasury; Joel R. Poinsett, of war; Mahlon Dickerson, of the navy; B. F. Butler, attorney general; and Amos Kendall, postmaster general. All of these except Mr. Poinsett had been members of President Jackson's cabinet at the close of his last term; but several changes were subsequently made, James K. Paulding becoming secretary of the navy and Felix Grundy attorney general in 1838, Henry D. Gilpin attorney general and John M. Niles postmaster general in 1840. The new administration commenced under most untoward circumstances. The business of the country, affected by excessive speculation and overtrading, and by sudden contractions and expansions of the currency, was on the verge of ruin. Within two months after the inauguration of the president the mercantile failures in the city of New York alone amounted to more than $100,000,000. Nearly the whole of Mr. Van Buren's term was occupied with attempts to remedy these evils by legislative measures for the establishment of a stable currency and a sound system of government finance. A favorite measure of the president was the independent treasury system for the custody of the public funds, which was ultimately sanctioned by congress, and is still in force. The war with the Seminoles was not ended till 1842. The pecuniary troubles were imputed in great measure to the financial policy of the administration by its political opponents; and, as the presidential election of 1840 approached, the state elections indicated that the democratic party was in danger of overthrow. A whig national convention (the congressional caucus system for nominating candidates having been abandoned) was held at Harrisburg, Dec. 4, 1839, and Gen. Harrison was nominated for president, with John Tyler for vice president. The national democratic convention met at Baltimore, May 5, 1840, and unanimously nominated Mr. Van Buren. The canvass was one of the most animated and exciting that have ever taken place, and the result was that Harrison and Tyler each received 234 electoral votes, and Van Buren 60 (those of New Hampshire, Virginia, South Carolina, Illinois, Alabama, Missouri, and Arkansas), while the same number were divided between R. M. Johnson, L. W. Tazewell, and James K. Polk as democratic candidates for the vice presidency. The popular vote was 1,275,011 for Harrison and 1,128,702 for Van Buren. Gen. Harrison was inaugurated March 4, 1841, and selected as his cabinet Daniel Webster, secretary of state; Thomas Ewing, of the treasury; John Bell, of war; George E. Badger, of the navy; Francis Granger, postmaster general; and J. J. Crittenden, attorney general. Before any distinctive line of policy could be adopted by the new administration, the president died, April 4. The presidential office devolved on John Tyler, who retained the cabinet of his predecessor until the following September, when all but the secretary of state resigned in consequence of the unexpected development of a policy on the part of the president in relation to a national bank much more in accordance with the views of the democratic party, to which he had formerly been attached, than to those of the whigs, by whom he had been elevated to power. A treaty was concluded in 1842 with Great Britain by Mr. Webster for the settlement of the northeastern boundary. On April 12, 1844, a treaty to annex Texas to the United States was concluded by Mr. Calhoun and the agents of the new republic, but was rejected by the senate, on the ground that it would involve the country in a war with Mexico. The Texas question immediately became the prominent issue in the presidential contest of that year, the democratic party supporting and the whigs opposing annexation. At the south it was advocated as a means of strengthening the slavery interest, and at the north it was in great part opposed for the same reason, the anti-slavery element in both the parties being at this period of considerable strength. The friends of Texas soon obtained control of the democratic party, and, Mr. Van Buren having expressed unconditional opposition to annexation, at the national convention of that party at Baltimore, May 27, 1844, James K. Polk was nominated for president, and George M. Dallas for vice president. The whig national convention, which met at Baltimore May 1, had already nominated for president Henry Clay, and for vice president Theodore Frelinghuysen. The result of the election was 170 electoral votes for Polk and Dallas, and 105 for the whig candidates. The popular vote was 1,337,243 for Polk and 1,299,062 for Clay. The management of the Texas question was now assumed by congress, and joint resolutions for annexing that country to the United States as one of the states of the Union were signed by President Tyler March 1, 1845; and his last important official act was to sign two days later the bill for the admission of Florida and Iowa into the Union.—President Polk appointed as his cabinet James Buchanan, secretary of state; Robert J. Walker, of the treasury; William L. Marcy, of war; George Bancroft, of the navy; Cave Johnson, postmaster general; and John Y. Mason, attorney general. At the beginning of his administration the country was involved in disputes with Mexico, growing out of the annexation of Texas to the United States. Gen. Zachary Taylor was sent with a small army to occupy the region between the Nueces and the Rio Grande, which the United States claimed as belonging to Texas, while the Mexicans maintained that Texas had never extended beyond the Nueces. In April, 1846, a slight collision occurred on the Rio Grande between Gen. Taylor's army and that of the Mexican commander, Gen. Arista. On May 11 the president sent a special message to congress declaring that "war existed by the act of Mexico," and asking for men and money to carry it on. Congress, by a vote of 142 to 14 in the house, and of 40 to 2 in the senate, appropriated $10,000,000, and gave authority to call out 50,000 volunteers. Taylor meanwhile had defeated the Mexicans at Palo Alto, May 8, and at Resaca de la Palma, May 9, and on being reënforced continued the war by brilliant victories at Monterey in September, and at Buena Vista, Feb. 23, 1847. (See TAYLOR, ZACHARY.) The conduct of the war was now assumed by Gen. Scott, commanding in chief. On March 9, 1847, he landed near Vera Cruz with about 12,000 men; that city was immediately besieged, and surrendered before the end of the month. Gen. Scott entered the city of Mexico on Sept. 14, after a series of hard-fought and uniformly successful battles. (See SCOTT, WINFIELD.) Meanwhile Gen. Stephen W. Kearny, at the head of a small force, had marched from Fort Leavenworth over the great plains to Santa Fé, and conquered New Mexico in August, 1846. He instituted an American government over the province, and then resumed his march toward California, which had already been conquered by Col. Fremont and Commodore Stockton. On his arrival at Monterey, Gen. Kearny assumed the office of governor, and on Feb. 8, 1847, proclaimed the annexation of California to the United States. While Kearny was on his way to California, Col. Doniphan, at the head of 1,000 Missouri volunteers, had made a prodigious march across the plains, and taken the city of Chihuahua, after routing, Feb. 28, 4,000 Mexicans, who met him about 18 m. from the city. Gen. Scott's army occupied the Mexican capital until after the ratification of a treaty of peace which was negotiated at Guadalupe Hidalgo, Feb. 2, 1848, by Nicholas P. Trist on the part of the United States. By this treaty Mexico granted to the United States the line of the Rio Grande as a boundary, and also ceded New Mexico and California. On their part the United States agreed to pay Mexico $15,000,000, and to assume the debts due by Mexico to American citizens to an extent not exceeding $3,500,000. At the beginning of the Mexican war negotiations in relation to the Oregon region were going on between Great Britain and the United States. "The whole of Oregon up to 54° 40′" had been one of the watchwords of the democratic party during the recent presidential canvass, and Mr. Polk in his inaugural address had declared that "our title to the country of the Oregon was clear and unquestionable." But Great Britain, on various pretexts, asserted a claim to the whole country, and the president after much negotiation finally offered as an amicable compromise the boundary of the parallel of 49°, with a modification giving to her the whole of Vancouver island, which was agreed to by Great Britain. The other important measures of Mr. Polk's administration were the revision of the tariff in 1846, by which its protective features were lessened, and the admission (1848) of Wisconsin into the Union as the 30th state, Florida and Texas having been admitted in 1845, and Iowa in 1846.—In the democratic national convention which met at Baltimore May 22, 1848, Lewis Cass was nominated for president, and William O. Butler for vice president. By the whig convention, which met at Philadelphia on June 7, Zachary Taylor and Millard Fillmore were nominated. The question of slavery had a powerful influence on the political combinations of this period. After the subsidence of the Missouri agitation in 1821, slavery attracted little attention until the establishment of the "Liberator" newspaper by William Lloyd Garrison at Boston, Jan. 1, 1831, and the formation of anti-slavery societies in the free states in 1832–'3 by Arthur Tappan and others. These societies relied exclusively on moral and religious influences to promote emancipation, and avoided political action, affirming that congress had no right to interfere with slavery in the states, though they petitioned that body to abolish slavery in the territories, in the District of Columbia, and wherever else the federal government had constitutional jurisdiction. Violent attempts were made to suppress the agitation throughout the country, resulting in many places in serious riots. Several of the southern legislatures called upon those of the north to suppress the movement by penal enactments. President Jackson in his message to congress in 1835 recommended the adoption of a law prohibiting the circulation of anti-slavery publications through the mails; and a bill for that purpose reached a third reading in the senate, but was finally rejected. In the house of representatives a rule was adopted in 1836 that all anti-slavery petitions should be laid on the table without reference or consideration; this rule was finally rescinded in 1845. In 1840 a disagreement among the abolitionists led to their separation into two divisions, one of which, consisting only of a few hundred men, under the lead of Mr. Garrison, in 1844 took the position that the compromises of the constitution on the subject of slavery were immoral, and that consequently it was sinful to swear to support that instrument or to hold office or vote under it, and that the union of the states was "an agreement with hell and a covenant with death," which ought to be at once dissolved. The other and far more numerous division of the abolitionists, with whom the followers of Mr. Garrison were often erroneously confounded, adhered to the Union and the constitution, and, having become satisfied that both the whig and democratic parties were completely under the control of the slaveholders, established in 1840 the "liberty party," and at a national convention held at Albany nominated James G. Birney for president and Thomas Earle for vice president. Their entire vote at the election of 1840 was 7,059. In 1844 Mr. Birney was again nominated for president, with Thomas Morris for vice president, and received 62,300 votes. These figures, however, imperfectly represented the numbers of the opponents of slavery, most of whom still maintained their connection with the two great parties, on whose action they had a powerful influence. In 1846, during the Mexican war, a bill being before congress authorizing the president to use $2,000,000 in negotiating a peace, David Wilmot, a democratic representative from Pennsylvania, moved to add thereto the proviso that, "as an express and fundamental condition to the acquisition of any territory from the republic of Mexico by the United States, by virtue of any treaty to be negotiated between them, and to the use by the executive of the moneys herein appropriated, neither slavery nor involuntary servitude shall ever exist in any part of said territory, except for crime, whereof the party shall be first duly convicted." This proviso was adopted in the house, nearly all the members from the free states voting for it, but failed in the senate from want of time. At the next session, 1846–'7, a similar bill appropriating $3,000,000 was finally passed without the proviso. On the termination of the war, the practical question involved in the Wilmot proviso, whether the introduction of slavery should be allowed or prohibited in the territories newly acquired from Mexico, became of prominent interest. In the whig national convention by which Gen. Taylor was nominated were several delegates from the northern states representing what were called "free-soil" opinions, that is, opinions hostile to the extension of slavery; several of these withdrew on the rejection of a resolution committing the party against the introduction or existence of slavery in the territories, and subsequently separated themselves from the whig party. A similar schism had already taken place in the democratic national convention of the same year, the "barnburners," as the free-soil democrats were termed, having seceded partly on anti-slavery and partly on personal grounds. An agreement was soon made between these seceding whigs and democrats and the liberty party to unite their forces in opposition to the extension of slavery; and a convention was held at Buffalo, Aug. 9, 1848, which was attended by delegates from all the free states and from Delaware, Maryland, Virginia, and the District of Columbia. A free-soil or free democratic party was formed, and Martin Van Buren was nominated for president and Charles Francis Adams for vice president. A platform was adopted, declaring that the new party was formed "to maintain the rights of free labor against the aggressions of the slave power, and to secure free soil to a free people; that slavery, in the several states of this Union which recognize its existence, depends upon the state laws alone, which cannot be repealed or modified by the general government, and for which laws that government is not responsible; we therefore propose no interference by congress with slavery within the limits of any state; that the only safe means of preventing an extension of slavery into territory now free is to prohibit its extension in all such territory by an act of congress; that we accept the issue which the slave power has forced upon us, and to their demand for more slave states and more slave territory, our calm but final answer is, no more slave states and no more slave territory." Van Buren and Adams received at the presidential election, in November, 1848, a popular vote of 291,263, but secured no electoral vote. The democratic candidates, Cass and Butler, received 127 electoral votes; and the whig candidates, Taylor and Fillmore, received 163 electoral votes, and were elected. The popular vote for Taylor was 1,360,099 and for Cass 1,220,544.—President Taylor was inaugurated on Monday, March 5, 1849, and appointed as his cabinet John M. Clayton, secretary of state; William M. Meredith, of the treasury; George W. Crawford, of war; William B. Preston, of the navy; Thomas Ewing, of the interior (an office created by congress two days before, March 3, 1849); Jacob Collamer, postmaster general; and Reverdy Johnson, attorney general. One of the earliest and most difficult of the questions which pressed on the new administration arose out of the acquisition of California, the people of which in 1849 framed a constitution prohibiting slavery. This being presented to congress early in 1850 with a petition for the admission of that region as a state, great excitement in congress and throughout the country arose. The extreme slavery party, led by Mr. Calhoun, demanded not only the rejection of California, but, among other concessions, an amendment of the constitution that should equalize the political power of the free and slave states. The question was still further complicated by the application of New Mexico for admission, and by a claim brought forward by Texas to a western line of boundary which would include a large portion of New Mexico. Finally a compromise was proposed by Henry Clay in the senate as a final settlement of the whole question of slavery, and after a long discussion the result aimed at by Mr. Clay was attained by separate acts, which provided for: 1, the admission of California as a free state; 2, territorial governments for New Mexico and Utah without excluding slavery, but leaving its exclusion or admission to the local population; 3, the settlement of the Texas boundary question; 4, the abolition of the slave trade in the District of Columbia; 5, the enactment of a stringent law for the arrest and return of fugitive slaves. Ten of the southern senators, including Mason and Hunter of Virginia, Soulé of Louisiana, and Jefferson Davis of Mississippi, published a final protest against the admission of California after the vote was taken; and the free-soil party at the north denounced the concessions to Texas and the refusal to prohibit slavery in New Mexico and Utah as unjust and unwise, and proclaimed the fugitive slave law unconstitutional, immoral, and cruel. While the compromise bills were yet before congress, President Taylor died, July 9, 1850, and was succeeded by the vice president, Millard Fillmore, who soon after reconstructed the cabinet as follows: Daniel Webster, secretary of state; Thomas Corwin, of the treasury; Charles M. Conrad, of war; Alexander H. H. Stuart, of the interior; William A. Graham, of the navy; Nathan K. Hall, postmaster general; and John J. Crittenden, attorney general. The acts relating to California, New Mexico, Utah, and Texas were signed by Mr. Fillmore on Sept. 9, the fugitive slave act on the 18th, and the District of Columbia act on the 20th; and the whole weight of his administration was given to the support of these measures. During the remainder of his term the events of most importance were the invasion of Cuba, in August, 1851, by a band of "filibusters" from New Orleans, led by Gen. Lopez, who was speedily captured and executed with many of his followers; the visit of Louis Kossuth to the United States in December, 1851; a dispute with England on the subject of the fisheries in 1852, which was settled by mutual concessions; and lastly the negotiation of a treaty with Japan by Commodore Perry, in command of an American fleet, by which the commerce of that empire was thrown open to the world.—On the approach of the presidential election of 1852 it became evident that, notwithstanding the apparent acquiescence of the great mass of the people in the compromise measures of 1850, the question of slavery was still a source of political agitation. The democrats of the south were divided into "Union men" and "southern rights men," the latter maintaining the right of a state to secede from the Union whenever its rights were violated by the general government. On the other hand, the whigs of the south were mostly Union men and satisfied with the compromise measures, while a majority of the whigs of the north were opposed to the fugitive slave law, though not offering resistance to its execution, and were still desirous of preventing the extension of slavery by national legislation. The democratic national convention met at Baltimore, June 1, 1852, and nominated for president Franklin Pierce of New Hampshire, who was known to hold opinions satisfactory to the south on the subject of slavery. William R. King of Alabama was nominated for vice president. The platform declared resistance to "all attempts at renewing in congress or out of it the agitation of the slavery question, under whatever shape or color the attempt may be made;" and also a determination to "abide by and adhere to a faithful execution of the acts known as the compromise measures settled by the last congress, the act for reclaiming fugitives from service or labor included." The whig national convention met at Baltimore, June 16, and nominated for president Gen. Winfield Scott and for vice president William A. Graham of North Carolina. The platform declared that "the series of acts of the 31st congress, commonly known as the compromise or adjustment, the act for the recovery of fugitives from labor included, are received and acquiesced in by the whigs of the United States as a final settlement in principle and substance of the subjects to which they relate; . . . . and we deprecate all further agitation of the questions thus settled, as dangerous to our peace, and will discountenance all efforts to continue or renew such agitation, whenever, wherever, or however made." The national convention of the free-soil party was held at Pittsburgh, Aug. 11, all the free states being represented, together with Delaware, Maryland, Virginia, and Kentucky. John P. Hale was nominated for president, and George W. Julian for vice president. A platform was adopted declaring "that the acts of congress known as the compromise measures of 1850, by making the admission of a sovereign state contingent upon the adoption of other measures demanded by the special interest of slavery, by their omission to guarantee freedom in the free territories, by their attempt to impose unconstitutional limitations on the power of congress and the people to admit new states, and by their invasion of the sovereignty of the states and the liberties of the people through the enactment of an unjust, oppressive, and unconstitutional fugitive slave law, are proved to be inconsistent with all the principles and maxims of democracy, and wholly inadequate to the settlement of the questions of which they are claimed to be an adjustment. That no permanent settlement of the slavery question can be looked for except in the practical recognition of the truth that slavery is sectional and freedom national; by the total separation of the general government from slavery, and the exercise of its legitimate and constitutional influence on the side of freedom; and by leaving to the states the whole subject of slavery and the extradition of fugitives from justice." At the election, Nov. 2, 1852, the democratic candidates, Pierce and King, received 254 electoral votes from 27 states. Scott and Graham received the 42 votes of Vermont, Massachusetts, Kentucky, and Tennessee. The popular vote for Pierce and King was 1,601,474, for Scott and Graham 1,386,578, and for Hale and Julian 155,825. President Pierce was inaugurated March 4, 1853, and appointed as his cabinet William L. Marcy, secretary of state; James Guthrie, of the treasury; Jefferson Davis, of war; James C. Dobbin, of the navy; Robert McClelland, of the interior; James Campbell, postmaster general; and Caleb Cushing, attorney general. One of the first questions that occupied the administration was a boundary dispute with Mexico concerning a tract of land bordering on New Mexico and comprising 45,535 sq. m., which finally by negotiation and purchase became a part of the United States. It is known as the Gadsden purchase, from the American minister who negotiated the treaty, and forms part of Arizona and New Mexico. In 1853 various expeditions were sent out to explore the routes proposed for a railroad from the Mississippi to the Pacific. In January, 1854, Stephen A. Douglas, chairman of the senate committee on territories, reported a bill for the organization of two new territories, Kansas and Nebraska, in the region west of Missouri and north of lat. 36° 30′. By this bill the Missouri compromise act of 1820 was repealed, and slavery allowed to enter where it had been formally and for ever excluded. The measure was warmly supported by the administration and by the leaders of the democratic party, and was strenuously opposed in debates of extraordinary length and interest by Chase and Wade of Ohio, Everett and Sumner of Massachusetts, Seward of New York, Fessenden of Maine, Houston of Texas, and Bell of Tennessee, in the senate, where it finally passed by a vote of 37 to 14. In the house it was opposed by Thomas H. Benton of Missouri and others; but it passed by a vote of 113 to 100, and the bill became a law on the last day of May. This bill roused great excitement and indignation in the free states, where it was denounced as a flagrant breach of faith, and its enactment greatly increased the strength of the anti-slavery party. Much dissatisfaction also was caused in those states by a conference at Ostend between the United States ministers to England, France, and Spain (Buchanan, Mason, and Soulé), in the circular issued by whom it was proposed to buy Cuba from Spain, or, if necessary to prevent emancipation in the island, to take it by force. The attempt to obtain Cuba was regarded at the north as prompted, like the repeal of the Missouri compromise, chiefly by a desire to extend and strengthen the slaveholding influence in the United States. So also were the filibuster expeditions against

Nicaragua led by William Walker, whose envoy at Washington, Vijil, was formally recognized by the president in 1856. (See Walker, William.) As, by the terms of the Kansas and Nebraska act, the people of those territories were to be left free to determine for themselves whether or not slavery should be tolerated there, a struggle soon began in Kansas, to which chiefly emigration was directed, between the anti-slavery and pro-slavery parties, which, after many acts of violence and a long period of confusion amounting almost to civil war, terminated in the adoption by the people of Kansas of a state constitution excluding slavery. (See Kansas.) In the course of the debates on the Kansas question Mr. Sumner of Massachusetts made a speech in the senate, May 19 and 20, 1856, and two days afterward was assailed in the senate chamber by Preston S. Brooks of South Carolina for expressions therein, and so much injured that he was long unable to resume his duties. This event increased still further the anti-slavery feeling at the north; and when the canvass for president began in 1856, an anti-slavery party appeared in the field of far more formidable dimensions than any previous organization of the kind. This party assumed the name of republican, and absorbed the entire free-soil party, the greater part of the whig party, and considerable accessions from the democratic party. The first decisive exhibition of its strength was the election in the congress of 1855–'6 of N. P. Banks, a former democrat, as speaker of the house of representatives. The whig party about this period disappeared from the field, that portion of it opposed to anti-slavery measures having been merged, especially at the south, in an organization called the American party from its opposition to foreign influence, and particularly to Roman Catholic influence, in our political affairs, but popularly known as the "Know-Nothing party" from the secrecy of its organization and the reticence of its members. This party held a national convention at Philadelphia, Feb. 22, 1856, and, after adopting a platform virtually recognizing the principles of the Kansas-Nebraska act and approving the fugitive slave law, nominated Millard Fillmore for president, and Andrew J. Donelson of Tennessee for vice president. The democratic national convention met at Cincinnati, June 2, and reaffirmed the Baltimore platform of 1852, with the addition of resolutions condemning the principles of the American party, recognizing the Kansas-Nebraska act as the only safe solution of the slavery question, affirming the duty of upholding state rights and the Union, and assenting generally to the doctrines of the Ostend circular. James Buchanan of Pennsylvania was nominated for president, and John C. Breckinridge of Kentucky for vice president. The republican national convention met at Philadelphia, June 17, and adopted a platform declaring that "the maintenance of the principles promulgated in the Declaration of Independence and embodied in the federal constitution is essential to the preservation of our republican institutions, and that the federal constitution, the rights of the states, and the union of the states shall be preserved;" and that "the constitution confers upon congress sovereign power over the territories of the United States for their government, and in the exercise of this power it is the right and the duty of congress to prohibit in the territories those twin relics of barbarism, polygamy and slavery." John C. Fremont of California was nominated for president, and William L. Dayton of New Jersey for vice president. The election resulted in the choice of Buchanan and Breckinridge by 174 electoral votes, against 114 for Fremont and 8 for Fillmore. The popular vote for Buchanan was 1,838,169, for Fremont 1,341,264, and for Fillmore 874,534. Fillmore received the vote of Maryland, Buchanan the votes of all the other slave states and of New Jersey, Pennsylvania, Indiana, Illinois, and California (19 in all), and Fremont those of the 11 remaining free states.—President Buchanan appointed as his cabinet Lewis Cass, secretary of state; Howell Cobb, of the treasury; John B. Floyd, of war; Isaac Toucey, of the navy; Jacob Thompson, of the interior; Aaron V. Brown, postmaster general; and Jeremiah S. Black, attorney general. With the exception of a rebellion of the Mormons in Utah in 1857–'8, which was suppressed without bloodshed, and of the admission into the Union of Minnesota in 1858 and of Oregon in 1859, the chief interest of Mr. Buchanan's administration centred around the slavery controversy, which still continued in Kansas, in the halls of congress, and in the legislatures of the free states. Several of the latter bodies, under the influence of a growing public opinion in opposition to the justice and constitutionality of the fugitive slave law, passed acts designed to impede its operation, and to secure to alleged fugitives the right to trial by jury and to the legal assistance usually given to those charged with criminal offences. These acts were commonly called personal liberty laws. An important element in the slavery controversy was the decision of the supreme court in the case of Dred Scott, rendered soon after the inauguration of Presidant Buchanan. (See Taney, Roger Brooke.) A constitution for Kansas framed at Lecompton in 1857 was laid before congress in the session of 1857–'8, and was strongly opposed by the republicans on the ground that it had been fraudulently concocted by the pro-slavery party there, that it did not represent the wishes of the people of Kansas, and that some of its provisions were cunningly framed for the purpose of forcing slavery into the new state in spite of the opposition of the inhabitants. A powerful section of the democratic party, headed by Stephen A. Douglas, sided with the republicans in this matter; but the so-called "Lecompton bill," submitting this constitution to the people under certain conditions, after a parliamentary struggle of extraordinary intensity and duration, was passed by congress by the votes of the democratic majority, led in the house by Alexander H. Stephens of Georgia, and in the senate by Jefferson Davis of Mississippi, John M. Mason of Virginia, and John Slidell of Louisiana. The president lent all his influence to the measure, on the ground that it would pacify the country, and would not prevent Kansas from becoming a free state if the people desired to exclude slavery. This contest resulted in a schism in the democratic party, and eventually in its division into two bodies, one of which looked upon Mr. Douglas as its leader, while the other supported for the presidency John C. Breckinridge of Kentucky. An attempt to free slaves by force of arms, made at Harper's Ferry in October, 1859, by John Brown of Kansas, for which he was hanged by the authorities of Virginia, Dec. 2, created a profound sensation throughout the country. (See BROWN, JOHN, vol. iii., p. 338.) In January, 1861, after the withdrawal of southern members of congress, Kansas was admitted into the Union under a constitution framed at Wyandotte in 1859.—The democratic national convention met at Charleston, April 23, 1860, and a controversy on the subject of slavery immediately arose. On the 30th a platform was adopted by a vote of 165 to 138, the essential portion of which was as follows: "Inasmuch as differences of opinion exist in the democratic party as to the nature and extent of the powers of a territorial legislature, and as to the powers and duties of congress, under the constitution of the United States, over the institution of slavery within the territories; resolved, that the democratic party will abide by the decisions of the supreme court of the United States on the questions of constitutional law." Most of the southern delegates thereupon withdrew, and on May 3 the convention adjourned to meet at Baltimore on June 18, after recommending that the vacant seats be filled prior to that date. The seceding delegates met, adopted a platform, and adjourned after calling a convention to assemble at Richmond on June 11. The portion of their platform relating to slavery was as follows: "That the government of a territory organized by an act of congress is provisional and temporary; and, during its existence, all citizens of the United States have an equal right to settle with their property in the territory, without their rights, either of person or property, being destroyed or impaired by congressional or territorial legislation. That it is the duty of the federal government, in all its departments, to protect, when necessary, the rights of persons and property in the territories, and wherever else its constitutional authority extends. That when the settlers in a territory having an adequate population form a state constitution, the right of sovereignty commences, and, being consummated by admission into the Union, they stand on an equal footing with the people of other states; and the state thus organized ought to be admitted into the federal Union, whether its constitution prohibits or recognizes the institution of slavery." The regular convention assembled in Baltimore pursuant to adjournment, and nominated Stephen A. Douglas of Illinois for president and Benjamin Fitzpatrick of Alabama for vice president, though a further withdrawal of delegates took place. Mr. Fitzpatrick subsequently declined, and Herschel V. Johnson of Georgia was substituted by the national committee. The convention called by the seceding delegates met first at Richmond, but adjourned, and convened finally at Baltimore on June 23, when it adopted the Charleston platform and nominated John C. Breckinridge of Kentucky for president and Joseph Lane of Oregon for vice president. The "Constitutional Union" party, composed mainly of the American party, held its national convention at Baltimore May 9, and nominated for president John Bell of Tennessee, and for vice president Edward Everett of Massachusetts. This party declared that it recognized "no political principle other than the constitution of the country, the union of the states, and the enforcement of the laws." The republican national convention assembled at Chicago on May 16, and nominated for president Abraham Lincoln of Illinois, and for vice president Hannibal Hamlin of Maine. The portion of the platform adopted by the convention relating to slavery was as follows: "That the maintenance of the principle promulgated in the Declaration of Independence and embodied in the federal constitution, 'that all men are created equal; that they are endowed by their Creator with certain unalienable rights; that among these are life, liberty, and the pursuit of happiness; that to secure these rights governments are instituted among men, deriving their just powers from the consent of the governed,' is essential to the preservation of our republican institutions; and that the federal constitution, the rights of the states, and the union of the states, must and shall be preserved. That the maintenance inviolate of the rights of the states, and especially the right of each state to order and control its own domestic institutions according to its own judgment exclusively, is essential to that balance of powers on which the perfection and endurance of our political fabric depend; and we denounce the lawless invasion by armed force of the soil of any state or territory, no matter under what pretext, as among the gravest of crimes. That the new dogma that the constitution, of its own force, carries slavery into any or all of the territories of the United States, is a dangerous political heresy, at variance with the explicit provisions of that instrument itself, with contemporaneous exposition, and with legislative and judicial precedent; is revolutionary in its tendency, and subversive of the peace and harmony of the country. That the normal condition of all the territory of the United States is that of freedom; that, as our republican fathers, when they had abolished slavery in all our national territory, ordained that 'no person should be deprived of life, liberty, or property, without due process of law,' it becomes our duty, by legislation whenever such legislation is necessary, to maintain this provision of the constitution against all attempts to violate it; and we deny the authority of congress, of a territorial legislature, or of any individuals to give legal existence to slavery in any territory of the United States." In the presidential election of Nov. 6, 1860, Mr. Lincoln received the electoral votes of all the free states (except three votes in New Jersey, which were given to Mr. Douglas), to the number of 180, and was elected. Mr. Bell received the votes of Virginia, Kentucky, and Tennessee, 39; Mr. Douglas the 9 votes of Missouri, which added to 3 from New Jersey gave him a total of 12 votes; and the remaining southern states cast their 72 electoral votes for Breckinridge. The popular vote for Lincoln was 1,866,452; for Douglas, 994,139; for Breckinridge, 669,082; for Bell, 575,193; and 575,327 votes were cast for fusion tickets opposed to Lincoln. The total vote was 4,680,193. When this result became known, the legislature of South Carolina ordered the election of a convention to consider the question of secession. The convention assembled Dec. 17, and on Dec. 20 unanimously adopted a secession ordinance, declaring that "the union now subsisting between South Carolina and other states, under the name of the United States of America, is hereby dissolved." The alleged reason for this action was hostility on the part of the successful party to the institution of slavery. Before the end of May, 1861, 11 states had passed ordinances of secession, in the following order: South Carolina, Mississippi, Florida, Alabama, Georgia, Louisiana, Texas, Virginia, Arkansas, Tennessee, and North Carolina. The western portion of Virginia refused to be bound by the ordinance of that state, and in 1863 was admitted into the Union as a separate state under the name of West Virginia. In eastern Tennessee also the prevailing sentiment continued favorable to the Union. On Feb. 4, 1861, a congress, composed of delegates from the states that had then seceded, assembled at Montgomery, Ala., and framed a constitution for the "Confederate States of America." Jefferson Davis of Mississippi was chosen president, and Alexander H. Stephens of Georgia vice president; a government was organized, and measures were taken to create an army. The senators and representatives from the seceded states withdrew from the United States congress. Nothing was done by President Buchanan's administration to thwart the purposes of the secessionists, who proceeded to seize the arsenals, custom houses, navy yards, and forts throughout the south. At the close of his term only Fort Sumter at Charleston, S. C., and Fort Pickens at Pensacola, Fla., with the posts on the Florida keys, remained in the possession of the government in the seven states that had then seceded. Various measures were proposed looking to conciliation, but without effect. For details of these, as well as of the progress of secession and the organization of the confederacy, see CONFEDERATE STATES OF AMERICA. In his inaugural address, March 4, 1861, President Lincoln declared that the accession of a republican administration afforded no ground to the southern states for apprehending any invasion of their rights, and that the power confided to him would be used "to hold, occupy, and possess the property and places belonging to the government, and collect the duties and imposts; but, beyond what may be necessary for these objects, there will be no invasion, no using of force against or among the people anywhere." "The course here indicated will be followed, unless current events and experience shall show a modification or change to be proper." (See LINCOLN, ABRAHAM.) He appointed as his cabinet William H. Seward, secretary of state; Salmon P. Chase, of the treasury; Simon Cameron, of war; Gideon Welles, of the navy; Caleb B. Smith, of the interior; Edward Bates, attorney general; and Montgomery Blair, postmaster general. The last two were from the slave states of Missouri and Maryland. In 1862 Cameron was succeeded by Edwin M. Stanton (Jan. 14) and Smith by John P. Usher; in 1864 Chase was succeeded by William P. Fessenden, Blair by William Dennison, and Bates by James Speed. Upon Lincoln's second inauguration (1865) Hugh McCulloch succeeded Fessenden. The army at the beginning of active measures on the part of the south was only 16,000 strong (on Jan. 1, 1861, it consisted of 16,402 officers and men, of whom 14,657 were present for duty), and by orders from Mr. Floyd, the secretary of war, who was himself a party to the secession movement, had been dispersed in the remotest parts of the country, while the navy was mostly absent on foreign stations. Under Floyd's orders also an extensive transfer of arms and ammunition from northern to southern arsenals was made during 1860. Before the inauguration of Mr. Lincoln Gen. Twiggs, commanding in Texas, had surrendered to the Texan authorities half the military force of the Union. Most of the army and many of the navy officers from the south resigned upon the secession of their states. The first warlike act was the bombardment by the confederates, under Gen. Beauregard, of Fort Sumter, which was commanded by Major Anderson with a garrison of 109 men. Fire was opened on April 12, 1861, and continued on the 13th, and Major Anderson was compelled to evacuate the fort on the 14th, sailing with his garrison to

New York. (See SUMTER, FORT.) The next day (April 15) President Lincoln issued a proclamation calling upon the governors of the several states for a force of 75,000 militia for three months. The utmost enthusiasm was aroused throughout the north. On the evening of the 16th several companies from Pennsylvania reached Washington, and on the 17th the 6th regiment of Massachusetts started for that city. On the 19th, in company with ten companies from Philadelphia, it reached Baltimore, where it was attacked by a party of secessionists, and three of its members were killed and eight seriously injured. The Philadelphia troops were compelled to return, but the 6th Massachusetts proceeded to Washington. On the 25th several other regiments reached that city. On May 13 Gen. B. F. Butler took military possession of Baltimore, repressing the secession element in that city. In the mean time the United States arsenal at Harper's Ferry (April 18), and the Gosport navy yard, near Norfolk, Va. (April 21), fell into the hands of the confederates. On April 19 and 27 the president issued proclamations declaring a blockade of the ports of the seceded states. On April 15 he called an extra session of congress to meet on July 4. This body made large appropriations for the organization and support of the army and navy, which were continued by subsequent congresses. Various loans were authorized and other financial measures adopted during the struggle, to which reference has been made in a previous portion of this article. The states and subordinate political bodies also promptly raised large sums in aid of the war, and did not relax their efforts till its close. Bounties were offered to soldiers enlisting, by the United States and by state and local authorities. On May 3, 1861, a second call was made by the president for 42,034 volunteers for three years, 22,714 men for the regular army, and 18,000 seamen. The acts of July 22, 25, and 31 authorized the president to accept not exceeding 1,000,000 volunteers for periods of from six months to three years. No formal call was made, but men came forward promptly under these acts, which were regarded in the apportionment of quotas as a call for 500,000 men for three years. On July 2, 1862, a call was made for 300,000 volunteers for three years, and on August 4 a draft was ordered of 300,000 men for nine months, to be made by the state authorities from the militia. On March 3, 1863, an act was passed providing for the enrolment and drafting of the military forces of the Union, and creating in the war department the bureau of the provost marshal general to carry it into effect. A draft was commenced under its provisions in July, which resulted in little direct benefit to the army, but served greatly to stimulate volunteering. This draft gave rise to severe riots in New York, continuing three days. On Oct. 17 a call was made for 300,000 volunteers for three years, followed by others on Feb. 1 and March 14, 1864, for 200,000 each for the same period. In April a draft was commenced to supply the deficiencies in these calls. On July 18 a call was made for 500,000 men for one, two, and three years, and on Dec. 19 another for 300,000 for the same periods; and these calls were followed by drafts. Recruiting was ordered to be discontinued on April 13, 1865. Simultaneously with the organization of the army measures were taken to enlarge the navy, which for service against the confederacy was largely recruited by the purchase of steamers and other vessels from the merchant marine.—On May 24, 1861, the national forces took possession of Arlington heights and Alexandria on the Potomac, opposite Washington. On the 27th federal troops under Gen. McClellan entered western Virginia. They soon obtained control of that part of the state, and at the close of the year scarcely any armed confederates were found W. of the Alleghanies in Virginia. On July 21 was fought the battle of Bull Run, near Manassas Junction, Va., the first of any magnitude during the war, in which the Union forces under Gen. McDowell were defeated by the confederates under Gen. Beauregard, and fell back in disorder to Washington. (See BULL RUN.) Soon after Gen. McClellan was placed in command of the army of the Potomac, and began to reorganize and discipline his forces, in which occupation the rest of the summer and the following winter were quietly passed. On Aug. 29 Forts Hatteras and Clark, at Hatteras inlet, the main entrance to Pamlico sound on the coast of North Carolina, were taken by a military and naval expedition under Gen. Butler and Com. Stringham. On Oct. 29 a fleet of 75 vessels under command of Com. Du Pont, with transports conveying 10,000 men under Gen. T. W. Sherman, sailed from Hampton roads, and on the night of Nov. 3 arrived off Port Royal, S. C. On the 7th they attacked Forts Beauregard and Walker at the entrance of the harbor, and after a bombardment of nearly five hours put the garrisons to flight, thus securing the finest harbor on the southern coast. Meantime troops in aid of the confederacy had been organized in Missouri, and others had come in from Arkansas and Texas. On Aug. 10 a battle was fought at Wilson's creek, near Springfield, in the S. W. part of Missouri, between the confederates under Gen. McCulloch and the federals under Gen. Lyon. The former lost 265 killed, 800 wounded, and 30 missing; the latter 223 killed (including Gen. Lyon), 721 wounded, and 292 missing. After the battle the Union army, under Col. Sigel, fell back to Rolla in the central portion of the state. Gen. Fremont, having been appointed to the command of the western department, took the field in Missouri near the end of September, and by degrees drove the confederates under Gen. Price back to the S. W. corner of the state; but on Nov. 2 he was superseded by Gen. Hunter. The federal army again fell back to Rolla, the confederates advancing as it receded. On the 12th Gen. Halleck took command of the department, and by the end of December Price was again in full retreat toward Arkansas, losing within a few days 2,500 prisoners and a large amount of stores. A conspicuous incident of the struggle in Missouri was the defence of Lexington, on the Missouri river, against a greatly superior force, by 2,780 men under Col. Mulligan, who surrendered (Sept. 21) only after being three days cut off from water. About Oct. 1 the confederate army before Washington began to fall back, and the national lines to be pushed forward. On the 21st a portion of Gen. Stone's command, having crossed the Potomac at Ball's bluff, about midway between Harper's Ferry and Washington, was disastrously defeated by the confederate general Evans, with a loss of 1,000 out of 1,900 men. Col. Baker, United States senator from Oregon, was among the killed. On Oct. 31 Winfield Scott, general-in-chief of the armies of the United States, retired from active service, and was succeeded by Gen. McClellan. On Nov. 8 Capt. Wilkes, in command of the frigate San Jacinto, intercepted the British mail steamer Trent, from Havana for Southampton, and forcibly took from on board Messrs. Mason and Slidell, commissioners from the southern confederacy to England and France. The action was resented by the British government, and produced a great display of feeling against the United States. A war with England seemed imminent, when the president decided to surrender the commissioners to the British minister. On Dec. 20 Brig. Gen. Ord routed the confederates with heavy loss at Dranesville, on the road from Washington to Leesburg. In the west, Bishop Polk of Louisiana, serving as major general in the confederate army, had occupied Hickman and Columbus, Ky., on the Mississippi, and begun to fortify them. Gen. Grant, commander of the federal forces at Cairo, Ill., consequently took possession (Sept. 6) of Paducah, on the Ohio just below the mouth of the Tennessee. About the same time Gen. Zollicoffer led a confederate force from Tennessee into S. E. Kentucky. This was subsequently placed under Gen. G. B. Crittenden, and was defeated on Jan. 19, 1862, by Gen. G. H. Thomas at Mill Spring, Zollicoffer himself being killed. On Feb. 6 the federal commodore Foote, with a fleet of gunboats from Cairo, reduced Fort Henry on the E. bank of the Tennessee river in Tennessee; and on the 16th Fort Donelson, on the W. bank of the Cumberland, surrendered with about 13,000 men after some severe fighting to Gen. Grant. (See FORT DONELSON AND FORT HENRY.) On the 15th Gen. Mitchel, advancing from Louisville, had occupied Bowling Green, Ky., a place of great natural strength, the confederate forces under Gen. A. S. Johnston retiring to Nashville, Tenn. That city was occupied by the federal forces on the 26th, Gen. Johnston retreating as far as Corinth, Miss.; and on March 2 Columbus, Ky., was evacuated by the confederates. The whole of Kentucky and a part of Tennessee were thus secured by the federal arms. To command the Mississippi, the confederates had fortified island No. Ten in a sharp bend of that river, a few miles above New Madrid, Mo., which was also fortified and defended by a confederate force. On March 3 Gen. Pope invested the town, which he took possession of on the 14th, the confederates having abandoned it during the preceding night, leaving 33 guns and a large quantity of small arms, ammunition, &c. Com. Foote, having in the mean time moved a fleet of gunboats down the river, opened on the island on the 15th. Two of the gunboats succeeded in running past it; and a canal 12 m. long having been cut through a peninsula on the Missouri side, enabling the fleet to get below it, Gen. Pope on April 7 crossed a portion of his troops to the E. side. The confederates, thus cut off from retreat, surrendered during the following night, and nearly 7,000 prisoners, 123 cannon, 7,000 stand of small arms, and an immense quantity of stores fell into the hands of the federals. The federal fleet proceeded down the river, and after some opposition from forts and gunboats received the surrender of Memphis on June 6. The command was now devolved on Com. Davis, Com. Foote having been disabled by a wound. The fleet continued its course down the river, reaching Vicksburg, Miss., before the end of June, where the first serious obstacle was encountered. In the mean time the federal forces under Gen. Grant had advanced from Fort Donelson up the Tennessee river, and when encamped in the vicinity of Shiloh church, Tenn., near Pittsburgh Landing on the river, were attacked by the confederates under Gens. A. S. Johnston and Beauregard, who had advanced from Corinth, about 20 m. distant. The battle, which at first threatened to overwhelm the federals, raged two days (April 6 and 7), when the confederates fell back to Corinth, leaving the field in the possession of the Union army. (See SHILOH.) After the battle Gen. Halleck assumed command of the Union army, and with augmented forces operated against Corinth, which the confederates evacuated on May 29. About the same time Gen. Mitchel entered N. Alabama, capturing Huntsville and other points, and destroying much confederate property. A confederate force had entered New Mexico from Texas early in 1862, but they were driven out before the close of the spring, and subsequently that territory was unmolested. A victory was gained by the national forces under Gen. Curtis at Pea Ridge, Ark., March 7 and 8, over the armies of Van Dorn, Price, and McCulloch, which had just been driven out of Missouri. Gen. Curtis subsequently met with little resistance, and in July occupied Helena on the Mississippi. During the latter half of the year there were numerous conflicts in Missouri and Arkansas between small forces of confederates and federals, the advantage being in favor of the latter. The battle of Prairie Grove, Ark., was fought on Dec. 7, the Union forces being commanded by Gens. Herron and Blunt, and the confederates by Gen. Hindman. The latter retreated during the ensuing night, leaving the federals in possession of the field. Ship island, about 10 m. from the coast of Mississippi, had been occupied in the latter part of 1861, and here troops were collected for the capture of New Orleans, to be under the command of Gen. Butler, who reached the island March 25, 1862. New Orleans was defended by Forts Jackson and St. Philip, on opposite sides of the Mississippi, about 83 m. below the city. Both of these works were of great strength, and between them the passage had been barred by chains and hulks. On April 18 a bombardment was commenced by a federal fleet of 47 vessels, carrying 289 guns and 21 mortars, the whole commanded by Capt. Farragut, the mortar fleet being under the special command of Capt. Porter. On the morning of the 24th, the barriers having been previously removed, Capt. Farragut ran past the forts with a part of his fleet, destroyed a squadron of the enemy's rams and gunboats, silenced the batteries above the forts, and reached New Orleans on the 25th. Gen. Lovell, in command of the confederate troops, evacuated the city on his arrival, and destroyed all the cotton, sugar, and other valuable stores. Forts Jackson and St. Philip surrendered to Capt. Porter on the 28th. Gen. Butler now moved up with his army, took formal possession of New Orleans (May 1), and placed it under martial law. Farragut's fleet passed up the river, captured Baton Rouge, and afterward proceeded to Vicksburg, the only remaining stronghold of the confederates on the Mississippi, of which a bombardment was begun on June 26. On the morning of the 28th Capt. Farragut with seven vessels passed the city, and joined Capt. Davis's flotilla from Memphis. The siege of Vicksburg was abandoned about the end of July, Capt. Farragut, who had repassed the batteries, dropping down the river with his fleet. On Aug. 5 the confederate Gen. Breckinridge was repulsed in an attack on Baton Rouge by Gen. Williams, who fell at the moment of victory. In December Gen. Butler was superseded by Gen. Banks. Another expedition, under the command of Gen. Burnside and Com. Goldsborough, sailed from Hampton roads Jan. 12, 1862, entered Pamlico sound by way of Hatteras inlet, and attacked Roanoke island, which the confederates had strongly fortified. The troops landed Feb. 7, and on the following day stormed the intrenchments, and obliged about 2,700 of the enemy to surrender. On the 9th the fleet passed up the sound to Elizabeth City, N. C., and destroyed the confederate flotilla. On March 14 Gen. Burnside captured New Berne after a severe battle, taking 500 prisoners and 69 guns, and immediately afterward marched a force thence to Beaufort, which made no resistance; but Fort Macon, which defended the entrance to it from the sea, held out until April 25. Washington, Plymouth, and other towns on the coast were also occupied. On April 11 Fort Pulaski, on Cockspur island at the mouth of the Savannah river, was reduced by bombardment from batteries on Tybee island. On March 8 the confederate ironclad Virginia (formerly Merrimack), coming out from Norfolk, attacked the federal fleet in Hampton roads, and destroyed the frigates Cumberland and Congress. During the ensuing night the ironclad Monitor, under command of Lieut. Worden, arrived from New York, and in the morning engaged the Virginia, which retired after a protracted contest. (See HAMPTON ROADS.) On May 10 Norfolk was occupied without resistance by a detachment from Fortress Monroe under Gen. Wool, and the Virginia was blown up to prevent it from falling into his hands. In June, 1862, Gen. Buell left Corinth, Miss., and moved east, threatening Chattanooga, Tenn. Gen. Bragg, in command of the confederates, thereupon moved from Tupelo, Miss., through N. Alabama and Georgia, reaching Chattanooga in advance of Buell. Toward the end of August he started on an invasion of Kentucky, which his forces entered from E. Tennessee. On the 30th a corps under Kirby Smith encountered a raw Union force under Gen. Manson at Richmond, Ky., and totally defeated it with a loss of several thousand in disabled and prisoners. Lexington was occupied on Sept. 4. On the 17th Bragg captured Munfordsville, with the Union force there of about 2,000 men under Col. Wilder, and on Oct. 1 entered Frankfort. In the mean time Buell had marched by way of Nashville, which he left strongly garrisoned, to Louisville, where his army arrived between Sept. 25 and 29. On Oct. 1 he began to move against Bragg, who slowly retreated to Perryville, where he made a stand, and on the 8th a battle ensued, in which the confederates lost 2,500 men and the federals more than 4,000. During the succeeding night Bragg continued his retreat, and joining Kirby Smith passed into E. Tennessee. On the 30th Buell was superseded by Maj. Gen. Rosecrans. The confederates under Gen. Price having occupied Iuka, Miss., Gen. Rosecrans attacked that place on Sept. 19, and severe fighting ensued, which was ended by darkness. During the succeeding night Price retreated, and at Ripley united with a stronger confederate force under Gen. Van Dorn, who soon advanced against Corinth, now defended by Gen. Rosecrans. The attack was commenced on Oct. 3, and ended on the following day with a strong and determined assault, which was repulsed with great loss, the federal pursuit continuing as far as Ripley. (See CORINTH, vol. v., p. 354.) Gen. Rosecrans, having assumed command in Kentucky, began on Nov. 10 to move to Nashville. On Dec. 26 he began to march thence upon Murfreesboro, where Bragg's forces were concentrated; he encountered some opposition, and reached Stone river near that place on the 29th and 30th. Here bloody engagements occurred, Dec. 31, 1862, and Jan. 2, 1863, which resulted in the abandonment of Murfreesboro by the confederates during the night of Jan. 3–4. (See MURFREESBORO.) The other operations in this vicinity during the winter and spring were confined to cavalry raids. On Nov. 28, 1862, Gen. Grant, in command in W. Tennessee, commenced an advance into Mississippi with the design of operating against Vicksburg. He had reached Oxford when, on Dec. 20, a blow was struck at his communications in the capture of Holly Springs by Van Dorn, who took more than 1,000 prisoners and destroyed a vast quantity of munitions and stores, compelling Grant to abandon the movement. On Oct. 8 Galveston, Texas, was occupied by a naval force, and was held till Jan. 1, 1863, when it was retaken by Gen. Magruder.—Operations of greater magnitude had in the mean while taken place on the eastern theatre of the war. About April 1, 1862, Gen. McClellan, who now had command only of the department of the Potomac, transferred his forces to Fortress Monroe, and began a movement upon Richmond up the peninsula between the York and James rivers. On the 4th an advance was made upon Yorktown, which was besieged for a month, when it was abandoned by the confederates. McClellan then continued his advance, and a series of bloody battles was fought, viz.: at Williamsburg, May 5; Hanover Court House, May 27; Seven Pines and Fair Oaks, May 31 and June 1; Mechanicsville, June 26; Cold Harbor, June 27; Savage's Station, June 29; Frazier's Farm, June 30; and Malvern Hill, July 1, on the James. During the night of July 1 Gen. McClellan withdrew his troops to Harrison's Landing, 7 m. below Malvern Hill, where he remained till about the middle of August, when his army was transferred to the Potomac. The confederate army in this campaign was at first commanded by Gen. Joseph E. Johnston, who was succeeded by Gen. Robert E. Lee. Soon after the battle of Malvern Hill it retired to Richmond, to assume the offensive against Washington. (For a detailed account of the peninsular campaign, see CHICKAHOMINY.) In the mean time a confederate force under Gen. "Stonewall" Jackson and federal forces under Gens. Banks and Fremont had been operating in the Shenandoah valley. (See CROSS KEYS.) Several battles were fought, and about the middle of June Jackson was summoned with the greater part of his force to Richmond. In July Gen. Pope was placed in command of the federal army of Virginia, consisting of the forces that had been operating in the valley and of those under Gen. McDowell covering Washington. About the same time Gen. Halleck was summoned from the west to act as general-in-chief at Washington. On Aug. 9 a portion of Pope's army under Banks was repulsed with loss at Cedar mountain, near Culpeper Court House, by a superior body of confederates under Jackson, who formed the van in Lee's offensive operations. On Aug. 29 and 30 occurred the second battle of Bull Run, between the Union army under Pope and the confederate forces under Jackson and Longstreet, in which the latter had the advantage. (See BULL RUN.) Pope retreated within the defences of Washington and resigned, Gen. McClellan assuming command of the remnant of his army. Lee moved to the Potomac above Washington and crossed into Maryland. McClellan soon started to meet him, and encountered portions of the enemy on Sept. 14 at Turner's and Crampton's gaps in the South mountain, from which they were driven after severe fighting. The next day Harper's Ferry, with 11,583 men, 73 guns, 13,000 small arms, and other stores, was surrendered to a detachment of Lee's army under Jackson. McClellan, advancing, found Lee on the 15th strongly posted across Antietam creek near the village of Sharpsburg, where on the two following days a bloody but indecisive battle was fought. (See ANTIETAM, BATTLE OF.) On the night of the 18th Lee retreated into Virginia. McClellan crossed the Potomac about Nov. 1, and advanced to Warrenton, near the Rappahannock. On the 7th he was directed to turn over the command to Gen. Burnside, who moved down the Rappahannock to Fredericksburg, which was summoned without effect on the 21st. Lee had made a parallel movement down the S. bank of the river, and strongly intrenched himself on the bluffs behind the town. On Dec. 13 Burnside crossed the river and made repeated attacks on the enemy's position, but was repulsed with great slaughter, and on the 15th returned to the N. bank. (See FREDERICKSBURG, BATTLE OF.) On Jan. 26, 1863, Burnside was superseded by Gen. Joseph Hooker. About the close of April Hooker began to cross the Rappahannock, and concentrated his forces at Chancellorsville, where a bloody engagement ensued, May 2–4, in which the Union army was worsted by the forces under Lee, Hooker recrossing to the N. side of the river. In this battle Jackson was mortally wounded. (See CHANCELLORSVILLE, BATTLE OF.) About the beginning of June Lee, again assuming the offensive, advanced into the Shenandoah valley, capturing Winchester on the 15th, whence he drove a federal force under Gen. Milroy, taking many prisoners. The main body of the confederate army crossed the Potomac above Harper's Ferry, June 24–25, and marching across Maryland entered Pennsylvania. Hooker had begun on June 13 to move north, so as to cover Washington, and on the 26th crossed the Potomac about half way between Washington and Harper's Ferry, advancing to Frederick, Md. On the following day he resigned his command, in consequence of a difference with Gen. Halleck respecting the disposition of a force at Maryland Heights opposite Harper's

Ferry, and on the 28th was succeeded by Gen. Meade. The latter advanced into Pennsylvania, and on July 1, 2, and 3 the two armies met in the great battle of Gettysburg, which ended in the discomfiture of the confederate army. (See GETTYSBURG, BATTLE OF.) On the 4th Lee began his retreat, and on the 13th recrossed the Potomac at one of the points where he had crossed on his advance. Meade crossed a little below Harper's Ferry on the 18th, and reached Warrenton on the 25th, where he was soon confronted by Lee on the other side of the Rappahannock. Few important movements were made by either army during the remainder of the year, and the campaign of 1863 closed with the abortive attempt of Meade upon Lee's position on Mine run, a small affluent of the Rapidan, at the end of November.—About Dec. 20, 1862, Gen. W. T. Sherman with 30,000 men proceeded down the Mississippi from Memphis, and on the 29th assaulted the fortifications and batteries commanding Vicksburg from the north. The assault was repelled with a loss of nearly 2,000, and the forces a few days after were withdrawn to Milliken's Bend, where on Jan. 4, 1863, Gen. McClernand assumed command. An expedition into Arkansas was immediately undertaken for the capture of Fort Hindman at Arkansas Post on the Arkansas river, which was reduced on the 11th, the federals suffering a loss of 977 and capturing 17 guns, several thousand prisoners and small arms, and a large quantity of munitions and stores. Returning from this expedition, the forces were moved down the Mississippi, and on the 22d landed at Young's Point on the W. bank, about 9 m. above Vicksburg, where Gen. Grant arrived and assumed chief command, Feb. 2. Two months were now spent in unavailing attempts to flank the defences of Vicksburg by means of a canal at this point and through various bayous. Finally, a part of Admiral Porter's fleet and several transports having run past the batteries of Vicksburg and Warrenton and Grand Gulf below, a portion of Grant's army, which had marched down the W. bank of the Mississippi, crossed the river on April 30. Grand Gulf, being thus taken in the rear, was abandoned on May 3, and a few days after Grant was joined by Sherman's corps, which had remained above Vicksburg. An advance was then made up the left bank of the Big Black river, encountering some opposition at Raymond (May 12) and Jackson (May 14). On the 16th a battle was fought at Champion Hills, between Jackson and Vicksburg, by Grant's forces, against Gen. Pemberton, who had marched out of Vicksburg with the design of taking Grant in the rear. Pemberton was driven back with loss, and retreated to the Big Black river, across which he was driven the following day. The federal forces then advanced upon Vicksburg, and on the 19th the investment was complete. Porter immediately obtained control of the Yazoo river. On the 19th and 22d unsuccessful assaults were made, in the latter of which the loss was nearly 3,000. On July 3, the last day of the battle of Gettysburg, Gen. Pemberton, reduced by famine, surrendered with 27,000 men, and on the 4th Grant occupied the city. The result of this campaign rent the confederacy in twain, and was the severest blow it had yet received. On July 16 Gen. Sherman drove out of Jackson Gen. Joseph E. Johnston, who during the siege had been operating in the rear of Grant. On July 3 Helena, Ark., held by Gen. Prentiss with 3,800, was attacked by about 7,700 confederates under Gen. Holmes, who were repulsed with a loss of nearly 1,700. In Louisiana Gen. Banks invested Port Hudson on the Mississippi in May, 1863, and on the 27th made an assault which was repulsed with a loss of about 1,850 men. The place was then closely besieged, and surrendered on July 8 with 6,408 men. Other operations were carried on during the year in Louisiana between Gens. Banks and Taylor, but they were not decisive. Early in September an expedition under Gen. Franklin, consisting of 4,000 men and several gunboats, was despatched from New Orleans to proceed against Houston, Texas, by way of Sabine pass; but the gunboats, being disabled in an attack on the fortifications at Pass Franklin, returned to New Orleans. On Oct. 26 a new expedition, consisting of 6,000 men under Banks, started for the Rio Grande, and landed at Brazos Santiago Nov. 2. Having taken possession of Brownsville and other points in W. Texas, Banks left Gen. Dana in command and returned to New Orleans. After abandoning Murfreesboro, Bragg had concentrated the greater part of his forces at Shelbyville and Tullahoma, where they were strongly intrenched. Rosecrans remained quietly at Murfreesboro till June 23, 1863, when he advanced, and took possession of Shelbyville on the 27th and of Tullahoma on the 30th, forcing Bragg to retreat to Chattanooga. The federal advance reached the Tennessee river Aug. 21, and by Sept. 8 the army was all across the stream, concentrating at Trenton, Ga., some miles S. of Chattanooga, which was occupied by a detachment the next day, Bragg retiring into Georgia and posting his troops in the vicinity of Chickamauga creek, E. of Trenton. Here, Sept. 19 and 20, occurred a severe engagement, in which the federals were worsted and fell back to Chattanooga, where they were besieged by Bragg. (See CHICKAMAUGA, BATTLE OF.) On Oct. 23 Gen. Grant arrived and took command. Reënforcements under Hooker had previously arrived from the east, and others from the west under Sherman came subsequently. A series of movements was at once initiated, which after much hard fighting resulted in driving Bragg from Chattanooga (Nov. 25) and forcing him to retreat into Georgia. (See CHATTANOOGA.) Gen. Burnside, after being relieved from command on the Rappahannock, had been assigned to the command of the department of the Ohio, and having organized a force of about 20,000 men at Camp Nelson near Richmond, Ky., began on Aug. 16 an advance on Knoxville, which was occupied on Sept. 1. East Tennessee, where the army was enthusiastically received by the population, was thus restored to the control of the Union with little opposition, the greater part of the confederate forces having been withdrawn to aid Bragg at Chickamauga. On Nov. 17 Longstreet, with forces drawn from Bragg, began a siege of Knoxville, which continued till the beginning of December, when, upon the approach of Sherman to the relief of the city, the confederates retreated into Virginia. A confederate cavalry force under Gen. Morgan, starting on June 27 from Sparta, Tenn., had made a raid, which created great excitement, through Kentucky and S. Indiana into Ohio, where before the end of July they were nearly all captured or destroyed. On Aug. 10 Gen. Steele set out from Helena, Ark., with 12,000 men and 40 guns, for the capture of Little Rock, and, advancing against some opposition, occupied that city on Sept. 10. Other operations in Arkansas and Missouri during the year were of minor importance. On April 6 an attack was made on Charleston by a fleet of ironclads under Com. Du Pont, which was repelled by the fire of Fort Sumter. On July 10 a force was landed by Gen. Gillmore, then in command in South Carolina, on Morris island at the entrance of Charleston harbor, and on the following day an ineffectual attack was made on Fort Wagner, a strong earthwork at its N. end. On the 18th an assault was made in force, which was repulsed with a loss of 1,500 men. The fort was then besieged by regular approaches, and was abandoned on Sept. 7. It was afterward, with other batteries on the island, turned against Charleston, which was nearly destroyed by the bombardment. On the night of Sept. 8 an attempt to carry Fort Sumter by assault was made by a flotilla of boats from Admiral Dahlgren's fleet, which was repulsed with a loss of about 80 killed and wounded and 120 prisoners. The principal occurrence in North Carolina during 1863 was the ineffective siege of the town of Washington in the early part of April by a confederate force under Gen. D. H. Hill. An effort in February, 1864, to restore Florida to the Union by an expedition from Hilton Head, under Gen. Seymour, resulted disastrously. Landing at Jacksonville, he advanced west, and at Olustee on the 20th encountered a confederate force under Gen. Finnegan and was compelled to retreat to Jacksonville. Of about 5,000 men engaged, Seymour lost about 1,500 in killed and wounded; the confederate loss was less than 1,000. On April 20 Plymouth, N. C., was compelled to surrender to a confederate force under Gen. Hoke (see Plymouth), and as a consequence Washington was evacuated by the federals eight days later. On May 5 the confederate ironclad Albemarle, which had taken part in the attack on Plymouth, came out of the Roanoke river and was engaged by the gunboat Sassacus. Having received considerable injury, the Albemarle retreated up the river, and on Oct. 27 was sunk by a torpedo under the direction of Lieut. Cushing. On Oct. 31 Plymouth was retaken by the federal fleet. West of the Mississippi, the most important movement in 1864 was Banks's disastrous Red river campaign in the early spring. (See Louisiana, vol. x., p. 678, and Red River, vol. xiv., p. 237.) In Arkansas Gen. Steele moved S. from Little Rock, March 23–24, with 7,000 men, for the purpose of coöperating with Banks, and advanced as far as Camden on the Washita river, when, receiving news of the failure of Banks, he began a retreat on April 27, reaching Little Rock May 2. During this movement Steele had been repeatedly annoyed by the confederates, the most important engagements being at Marks's mill on April 25, when a detachment of three regiments was captured after a stout resistance by a superior force under the confederate Gen. Fagan, and at Jenkins's ferry on the Saline river, April 30, when a powerful attack by Kirby Smith was repulsed with great loss. In September and October Gen. Price with a considerable force made a raid through Missouri. Entering the state at the S. E. corner from Arkansas, he passed N. W. through the centre past Jefferson City to Lexington and Independence, whence he was driven south, escaping into W. Arkansas with a loss of 10 guns, much material, and nearly 2,000 prisoners. On April 12 Fort Pillow, on the Mississippi about 40 m. above Memphis, garrisoned by about 550 men, of whom half were colored, was taken by assault by the confederates under Gen. Forrest, and many of the garrison as well as non-combatants were killed after the capture. Gen. Sturgis with 12,000 men, being sent after Forrest, who was retreating, came up with and was routed by him at Guntown in N. Mississippi on June 10. Sturgis lost 3,000 or 4,000 men, mainly prisoners, and retreated to Memphis, pursued by Forrest. Another force of 12,000 men under Gen. A. J. Smith was then sent against Forrest, by which he was defeated with great loss at Tupelo, Miss., on July 14. In August Forts Gaines and Morgan, commanding the entrance to Mobile bay, were reduced by a fleet under Admiral Farragut, aided by a land force under Gen. Granger, and the confederate fleet there was destroyed. (See Mobile.)—Early in March, 1864, Gen. Grant was appointed lieutenant general and invested with the chief command of the Union armies, Gen. Halleck being relieved and assigned to duty in Washington as chief of staff to the army. Gen. Grant announced that his headquarters would be with the army of the Potomac in the field. On May 4 he began to cross the Rapidan and advance into the "Wilderness," a region on the S. bank of that stream in Orange and Spottsylvania counties.

Here (May 5 and 6) and at Spottsylvania Court House near by (May 8-21) followed a series of sanguinary engagements. (See WILDERNESS, BATTLES OF THE.) Grant then advanced by a series of flank movements to the Chickahominy, where on June 3 occurred the second battle of Cold Harbor, in which the federal assault on the confederate position was repulsed with great loss. (See CHICKAHOMINY, vol. iv., p. 416.) On the 12th, having determined to attack Richmond from the south, he began to move, crossing the Chickahominy below Lee's position, and effecting the passage of the James June 14-15. Lee thereupon retired within the intrenchments covering Richmond. On the 15th and 16th a part of the Union forces unsuccessfully assailed Petersburg, and on the 19th Grant began a regular siege. On July 30, a mine having been exploded, another attack was made, which was repulsed with loss. The siege of Petersburg and Richmond continued till April 3, 1865, when, after Lee's defeat at Five Forks (March 31, April 1), those places were occupied by the federals, having been evacuated by Lee during the preceding night. Grant vigorously pursued the retreating army, and at Appomattox Court House on the 9th compelled Lee to surrender the remnant of his forces, about 27,000 in all, an event which virtually terminated the war. (See PETERSBURG, SIEGE OF.) Simultaneously with Grant's advance on Richmond, Gen. Sigel moved up the Shenandoah valley, and Gen. Crook from Charleston, W. Va., up the Kanawha valley. On May 15, 1864, Sigel was routed at Newmarket by Gen. Breckinridge, losing 700 men, 6 guns, and 1,000 small arms. Gen. Hunter, having superseded Sigel and having been somewhat strengthened, resumed the offensive. He was opposed by Gen. Jones, Breckinridge having been withdrawn to Richmond. The two armies met at Piedmont, near Staunton, June 5, when Jones was routed, losing 1,500 prisoners, 3 guns, and 3,000 small arms. Hunter advanced to Staunton, where he was joined by Crook, and advanced thence via Lexington on Lynchburg. Gen. Early being sent to the relief of this city from Richmond, Hunter retreated into West Virginia. Early then moved north, and on July 2-3 appeared on the Potomac. Crossing into Maryland, he threatened Washington and Baltimore, being stoutly but ineffectually opposed on the 9th by an inferior force under Gen. Wallace on the Monocacy river near Frederick, Wallace losing nearly 2,000 men in killed, wounded, and missing. Washington was saved by the timely arrival of troops ordered there by Gen. Grant. Early recrossed into Virginia, and on the 24th routed Gen. Crook near Winchester, inflicting a loss of 1,200. He then sent a body of cavalry on a raid into Pennsylvania, which burned Chambersburg, July 30. On Aug. 7 Gen. Sheridan was placed in command of the federal forces to operate in the Shenandoah valley. His force was soon raised to 30,000, Early opposing him with about 20,000. He defeated Early on Opequan creek near Winchester (Sept. 19), at Fisher's Hill 8 m. S. (Sept. 22), and on Cedar creek near by (Oct. 19), virtually clearing the valley of confederate troops. In the battle of Opequan creek he lost 3,000 men, and captured the same number of prisoners and 5 guns; in that of Fisher's Hill he took 1,100 prisoners and 16 guns. In the battle of Cedar creek Early surprised the Union camp at dawn in the absence of Gen. Sheridan, driving back the troops in confusion and capturing the camp and defences, 24 guns, and 1,200 prisoners. Sheridan, then at Winchester, being aroused by the firing, hurried to the front, and having reorganized his troops, retook the camp and guns in the afternoon, recovering many of the prisoners taken in the morning, and taking from the enemy 1,500 prisoners, 23 guns, and 1,500 small arms, besides equipments.—When Gen. Grant assumed the chief command, Gen. W. T. Sherman was placed in command of the division of the Mississippi, comprising the departments of the Ohio, the Cumberland, the Tennessee, and the Arkansas, and was to move against Atlanta, Ga., simultaneously with Grant's advance on Richmond. His forces for the campaign were encamped around Chattanooga, and consisted of a little less than 100,000 men, with about 250 guns, comprising the army of the Cumberland, Gen. Thomas; the army of the Tennessee, Gen. McPherson; and the army of the Ohio, Gen. Schofield. He was opposed by Gen. J. E. Johnston, with about 50,000 men, encamped at Dalton, Ga., organized in three corps under Hardee, Hood, and Polk. Sherman started on May 5, and gradually forced Johnston back, compelling him after much severe fighting to cross the Chattahoochee on July 10 and seek the intrenchments covering Atlanta. Here he was superseded by Hood, who made several attacks on Sherman, which were repulsed with great loss, and was compelled to abandon Atlanta on Sept. 1. (See ATLANTA, and SHERMAN, WILLIAM TECUMSEH.) Having removed the inhabitants from the city and burned everything except the dwellings and churches, Gen. Sherman started near the middle of November for the coast, with about 60,000 men. Marching through the heart of Georgia without opposition, he reached the vicinity of Savannah. On Dec. 13 Fort McAllister on the Ogeechee river, in the rear of Savannah, was carried by assault by Gen. Hazen, and communication was then opened with the fleet. On the 21st Savannah was occupied, having been abandoned by its garrison during the preceding night. Sherman left Gen. Thomas in command in Tennessee. Hood, after abandoning Atlanta, had operated for a time upon Sherman's line of communication, and then moved into N. Alabama, whence, upon learning that Sherman had started for the coast, he advanced into Tennessee with about 55,000 men, and began to move on Nashville. On Nov. 30 he was opposed at Franklin by

Gen. Schofield, who repelled repeated assaults, enabling the federal trains to cross the Harpeth river and reach Nashville. The federal loss was 189 killed, 1,033 wounded, and 1,104 missing; the confederate loss was reported by Thomas at 1,750 killed, 3,800 wounded, and 702 prisoners, while Hood admitted a total loss of 4,500. A little after midnight Schofield withdrew, and the next day reached Nashville. Hood established his lines S. of Nashville, and was attacked by Thomas on Dec. 15 and 16, and completely routed. He retreated with difficulty into Alabama, having suffered immense losses in disabled and prisoners. (See NASHVILLE.) An attempt in December, by a fleet under Admiral Porter and a land force under Gen. Butler, to reduce Fort Fisher at the mouth of Cape Fear river, commanding the approach to Wilmington, N. C., failed; but on Jan. 15, 1865, it was carried by assault under Gen. Terry, aided by the fleet. During the following night the confederate works on the opposite side of the river were abandoned and blown up. The federal forces, reënforced by troops under Gen. Schofield, occupied Wilmington on Feb. 22, the confederates under Gen. Hoke retreating. On Feb. 1 Gen. Sherman started from Savannah on a northward movement through the Carolinas, and reached Columbia on the 17th. Gen. Hardee, being thus taken in the rear, evacuated Charleston, which was occupied by a detachment of Gen. Gillmore's forces on the 18th, and the same day the United States flag was raised over Fort Sumter. Sherman continuing his march reached Fayetteville, N. C., on March 12. On the 19th the left wing under Slocum encountered the confederate army under Gen. Johnston at Bentonville, repelled several assaults, and on the 21st, being reënforced, compelled it to retreat to Smithfield, covering Raleigh. Sherman then occupied Goldsboro, whence he advanced on April 10. Johnston retreated to and through Raleigh, and on April 26 surrendered his entire army, then reduced to about 31,000 men. In the mean time a cavalry force under Gen. Wilson had swept through Alabama from the north, and passed into Georgia, doing immense injury to the confederate resources. He occupied Selma on April 2, Montgomery on the 12th, and Columbus, Ga., on the 16th. At Selma he took 32 guns and 2,700 prisoners, and at Columbus 52 guns and 1,200 prisoners, and in both places destroyed numerous factories and a vast amount of stores. Toward the end of March operations were begun for the reduction of Mobile by Gen. Canby, with a force from New Orleans aided by a fleet under Admiral Thatcher. Spanish Fort and Blakely, commanding the city from the east, were taken on April 9, and Mobile was occupied on the 12th, Gen. Maury with 9,000 men fleeing up the Alabama river. (See MOBILE.) On May 4 Gen. Taylor surrendered the confederate forces in Alabama to Gen. Canby. The last fight of the war occurred, May 13, on the Rio Grande in Texas, between Col. Barrett (federal) and Gen. Slaughter (confederate), the latter being victorious. The trans-Mississippi army of the confederates, the last in the field, was surrendered by Kirby Smith on May 26. Measures were immediately taken to disband the federal armies, and in a few months the greater part of the soldiers had returned to civil life.—The strength of the national armies at different periods was as follows: July 1, 1861, 186,751; Jan. 1, 1862, 575,917; Jan. 1, 1863, 918,191; Jan. 1, 1864, 860,737; Jan. 1, 1865, 959,460; May 1, 1865, 1,000,516. At the last date the number of men enrolled as subject to military duty, but not called out, was 2,254,063. The whole number of men called for by the government was 2,759,049; number furnished, 2,666,999 (equivalent to 2,135,000 for three years), of whom 186,097 were colored. This does not correctly represent the number of different persons under arms, as it includes reënlistments. A considerable number of men called out for short periods upon emergencies are not included. The total includes some who enlisted in the navy. Only a small number were obtained by the drafts, the result being as follows: held to personal service, 46,347; furnished substitutes, 73,607; paid commutation, 86,724; total, 206,678, to which should be added 87,588 credited to the states under the draft of 1862. The amount of commutation money received by the government was $26,366,316 78. The number of men who received the United States bounty ($100 to $400 each) was 1,722,690; amount paid, $300,223,500. The amount of bounties paid by states and local authorities, so far as returned, was $285,941,036. The casualties in the army numbered 280,739, viz.: 5,221 officers and 90,868 men killed in action or died of wounds, and 2,321 officers and 182,329 men died from disease or accident. These numbers do not include deaths after leaving the army from wounds or disease contracted in the service. The above statistics are compiled from the report of the provost marshal general ("Message and Documents, War Department, 1865–'6").—During the war confederate cruisers, mostly built and fitted out in British ports, scoured the ocean. Evading vessels of war, they destroyed hundreds of merchantmen, doing irreparable injury to the commerce of the Union. The chief of these were the Alabama, Chickamauga, Florida, Georgia, Olustee, Shenandoah, Sumter, and Tallahassee. The Alabama, the most famous, commanded by Raphael Semmes, was sunk off Cherbourg, France, June 19, 1864, by the United States steamer Kearsarge, commanded by Capt. Winslow. A presidential proclamation of June 23, 1865, removed the blockade of all the ports in the southern states, and another of Aug. 29 annulled all restrictions upon trade with them. On April 2, 1866, the insurrection was proclaimed at an end in all the states except Texas, and there on Aug. 20. After the fall of Richmond President Davis of the confederacy fled south, and was captured at Irwinville, Ga., by Gen. Wilson's forces, May 10, 1865. He and some other prominent leaders were imprisoned for a time, but no man was punished for participation in the rebellion. On May 29, 1865, the president issued an amnesty proclamation, excepting 14 classes of those most prominent in the rebellion. This was followed by others on Sept. 7, 1867, July 4, 1868, and Dec. 25, 1868, the last making the amnesty universal.—A peculiar feature of the war was the voluntary organizations of citizens to promote the moral and physical welfare of the soldiers. The chief of these were the United States sanitary commission, the United States Christian commission, and the Western sanitary commission, organized in 1861. The sanitary commissions were designed to coöperate with the medical bureau of the war department, and performed valuable services in the prevention of disease, in supplying food, clothing, and hospital stores, in the relief of prisoners, and in other ways. They had branches throughout the north, and received large contributions in money and supplies. The Christian commission was composed of representatives of the young men's Christian associations, and performed services similar to those of the sanitary commissions, together with others of a more strictly religious character. Toward and after the close of the war various societies were organized for the relief of Union refugees from the south, the care of the freedmen, and the restoration of industry and education in the region devastated by war. By the act of March 3, 1865, the bureau of refugees, freedmen, and abandoned lands was created in the war department. (See FREEDMEN.)—The question of emancipation early attracted the attention of the president and congress. On April 16, 1862, an act was passed abolishing slavery in the District of Columbia, and on June 9 another act declared that slavery should not thereafter exist in the territories. The act of July 17 declared that all slaves of persons who should thereafter be engaged in rebellion, escaping and taking refuge within the lines of the army, all slaves of such persons captured, or deserted and coming under the control of the United States, and all slaves of such persons found in any place occupied by rebel forces and afterward occupied by the federal forces, should be free. The same act authorized the president to receive into the military and naval service persons of African descent. On Jan. 1, 1863, the president issued a proclamation, in pursuance of a warning contained in a proclamation of Sept. 22, 1862, declaring free all persons held as slaves within the states or portions of states then in rebellion. (See SLAVERY.) On April 8, 1864, a joint resolution amending the federal constitution, by declaring that slavery shall not exist within the United States or any place subject to their control, passed the senate by a vote of 38 to 6, and on Jan. 31, 1865, it was approved by the house of representatives by a vote of 119 to 56. This, known as the thirteenth amendment, the secretary of state on Dec. 18, 1865, proclaimed ratified by the legislatures of three fourths of the states, and consequently valid to all intents and purposes as a part of the constitution. The first step toward the reconstruction of loyal governments in the seceded states was the proclamation of President Lincoln of Dec. 8, 1863. This promised full pardon, with restoration of rights of property, except as to slaves, to all persons (with some exceptions) who had participated in the rebellion, upon condition that they should take and maintain an oath to support and defend the constitution of the United States and the union of the states thereunder, and to abide by all acts of congress and proclamations of the president having reference to slaves. It also provided that when in any of the seceded states persons, not less in number than one tenth of the votes cast at the presidential election of 1860 in that state, who had taken and not violated the oath and were qualified voters by law of the state in force immediately before secession, should reëstablish a republican government in no wise contravening the oath, such government should be recognized as the true government of the state. Under this scheme governments were organized in Louisiana and Arkansas in the early part of 1864, and in Tennessee early in 1865, but senators and representatives from those states were not admitted to congress. After the close of the war President Johnson recognized these governments, and also recognized Francis H. Pierpont as governor of Virginia, who after the admission of West Virginia had exercised jurisdiction in a few counties adjacent to Washington. On May 29, 1865, President Johnson appointed a provisional governor of North Carolina, and in June and July similar officers were appointed for Mississippi, Georgia, Texas, Alabama, South Carolina, and Florida. It was made the duty of the provisional governor in each state to call a convention, the delegates to which were to be elected by those who were qualified voters by the laws in force in the respective states immediately previous to secession, and who had taken the oath prescribed by the amnesty proclamation of the same date, similar to that of Lincoln's, for the purpose of restoring these states to their constitutional relations to the federal government. Conventions were accordingly held during the year in all these states except Texas, where a convention met in 1866. Ordinances were passed abolishing slavery, declaring the debt incurred in aid of the confederacy void, and repealing the ordinances of secession. State officers and congressmen were elected, and the legislatures ratified the thirteenth amendment. But congress did not approve this scheme of reconstruction, and senators and representatives from those states were not admitted.

On April 9, 1866, the "civil rights bill" was passed by congress over the president's veto; it enacted "that all persons born in the United States and not subject to any foreign power, excluding Indians not taxed, are hereby declared to be citizens of the United States; and such citizens of every race and color, without regard to any previous condition of slavery or involuntary servitude, except as a punishment for crime whereof the party shall have been duly convicted, shall have the same right in every state and territory in the United States to make and enforce contracts; to sue, be parties, and give evidence; to inherit, purchase, lease, sell, hold, and convey real estate and personal property; and to full and equal benefit of all laws and proceedings for the security of person and property, as is enjoyed by white citizens, and shall be subject to like punishment, pains, and penalties, and to none other; any law, statute, ordinance, regulation, or custom to the contrary notwithstanding." The United States courts were given jurisdiction of offences against this act. On June 8 a joint resolution passed the senate by a vote of 33 to 11, and on the 13th was approved by the house by a vote of 138 to 36, proposing an amendment to the constitution, which is known as the fourteenth amendment. It provides that "all persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the state wherein they reside," and that "no state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States;" that when the right of suffrage in any state "is denied to any of the male inhabitants of such state, being 21 years of age, and citizens of the United States, or in any way abridged, except for participation in rebellion or other crime, the basis of representation therein shall be reduced in the proportion which the number of such male citizens shall bear to the whole number of male citizens 21 years of age in such state;" that "the validity of the public debt of the United States, authorized by law, including debts incurred for payment of pensions and bounties for services in suppressing insurrection or rebellion, shall not be questioned;" and that "neither the United States, nor any state, shall assume or pay any debt or obligation incurred in aid of insurrection or rebellion against the United States, or any claim for the loss or emancipation of any slave." It also incapacitates from holding office certain classes of persons who shall have engaged in insurrection or rebellion against the United States, or given aid or comfort to the enemies thereof; but congress may by a vote of two thirds of each house remove such disability. Under this power the disabilities have been removed from great numbers by special acts, and by the act of May 22, 1872, from all "except senators and representatives of the 36th and 37th congresses, officers in the judicial, military, and naval service of the United States, heads of departments, and foreign ministers of the United States," who joined the confederate cause. In July, 1866, senators and representatives were admitted from Tennessee, that state having ratified the fourteenth amendment. On Jan. 8, 1867, an act was passed over President Johnson's veto conferring the right of suffrage on colored citizens of the District of Columbia, and on the 24th a similar act became a law for the territories. The congressional plan of reconstruction was developed in the act of March 2 and the supplementary acts of March 23 and July 19, each of which was passed over the president's veto. These acts declared that "no legal state governments or adequate protection for life or property now exist in the rebel states of Virginia, North Carolina, South Carolina, Georgia, Alabama, Mississippi, Louisiana, Florida, Texas, and Arkansas," and divided them into five military districts. It was made the duty of the president to assign to the command of each of these districts an officer of the army not below the rank of brigadier general, and to detail a sufficient military force to enable each officer to enforce his authority. The district commanders were required to make a registration of voters, comprising male citizens of the United States 21 years old and upward, without regard to race, color, or previous condition, who had resided in the respective states one year and were not excluded from holding office by the fourteenth amendment. Upon registration voters were required to take and subscribe an oath, declaring among other things that they had not been disfranchised for participation in any rebellion or civil war against the United States; that they had never been members of any state legislature, nor held any executive or judicial office in any state, nor taken an oath in an official capacity to support the constitution of the United States, and afterward engaged in insurrection or rebellion against the United States, or given aid or comfort to the enemies thereof; and engaging faithfully to support the constitution and obey the laws of the United States, and to encourage others to do so. Delegates were to be elected in the several states by the registered voters to conventions for framing new constitutions. Only when constitutions had been adopted conferring the right of suffrage on colored persons, and such constitutions had been approved by congress, and when the fourteenth amendment had been ratified by the legislatures of the respective states, were senators and representatives to be admitted. The conditions of these acts were complied with in Alabama, Arkansas, Florida, Georgia, Louisiana, North Carolina, and South Carolina in 1868, and in Mississippi, Texas, and Virginia in 1870. But in Georgia the subsequent action of the legislature in excluding colored members led to further measures on the part of congress, and delayed the final restoration of that state until 1870. The adoption of the fourteenth amendment was proclaimed on July 28, 1868. On Feb. 25, 1869, a joint resolution proposing an amendment to the constitution, known as the fifteenth amendment, passed the house of representatives by a vote of 144 to 44, and on the following day was approved by the senate by a vote of 39 to 13. Its adoption was proclaimed on March 30, 1870. The amendment is as follows: "The right of citizens of the United States to vote shall not be denied or abridged by the United States, or by any state, on account of race, color, or previous condition of servitude." —The second election of Lincoln had taken place before the close of the war, and just previous to the election Nevada had been admitted into the Union. The national republican convention assembled at Baltimore on June 7, 1864, and nominated President Lincoln for reelection, and for vice president Andrew Johnson of Tennessee. The platform adopted contained the following resolutions: "That it is the highest duty of every American citizen to maintain against all their enemies the integrity of the Union, and the paramount authority of the constitution and laws of the United States; and that, laying aside all differences of political opinion, we pledge ourselves as Union men, animated by a common sentiment, and aiming at a common object, to do everything in our power to aid the government in quelling by force of arms the rebellion now raging against its authority, and in bringing to the punishment due to their crimes the rebels and traitors arrayed against it. That, as slavery was the cause, and now constitutes the strength of the rebellion, and as it must be, always and everywhere, hostile to the principles of republican government, justice and the national safety demand its utter and complete extirpation from the soil of the republic; and that, while we uphold and maintain the acts and proclamations by which the government in its own defence has aimed a death blow at this gigantic evil, we are in favor furthermore of such an amendment to the constitution, to be made by the people in conformity with its provisions, as shall terminate and for ever prohibit the existence of slavery within the limits or the jurisdiction of the United States." The national democratic convention assembled at Chicago on Aug. 29, and nominated Gen. George B. McClellan for president, and for vice president George H. Pendleton of Ohio. The platform declared adherence to the Union under the constitution, and contained the following resolution: "That this convention does explicitly declare, as the sense of the American people, that after four years of failure to restore the Union by the experiment of war, during which, under the pretence of a military necessity, or war power higher than the constitution, the constitution itself has been disregarded in every part, and public liberty and private right alike trodden down and the material prosperity of the country essentially impaired, justice, humanity, liberty, and the public welfare demand that immediate efforts be made for a cessation of hostilities, with a view to an ultimate convention of the states, or other peaceable means, to the end that at the earliest practicable moment peace may be restored on the basis of the federal union of the states." The election took place on Nov. 8, the eleven seceded states not participating. McClellan and Pendleton received the electoral votes of New Jersey, Delaware, and Kentucky, 21; Lincoln and Johnson received those of all the other states, 212, and were elected. The popular vote was 2,213,665 for Lincoln, and 1,802,237 for McClellan. On March 4, 1865, Lincoln's second inauguration took place. On April 14 he was assassinated (see LINCOLN, ABRAHAM), and on the following day Vice President Johnson entered upon the duties of the presidency. In July, 1866, Postmaster General Dennison, Attorney General Speed, and Secretary of the Interior Harlan resigned, and were succeeded by Alexander W. Randall of Wisconsin, Henry Stanbery of Ohio, and Orville H. Browning of Illinois. The difference between the president and congress on the question of reconstruction led to his separation from the republican party, and to the passage on March 2, 1867, over his veto, of the "tenure of office" act, which took from the president the power to remove without the consent of the senate such civil officers as are appointed by the president with the consent of the senate. In August, 1867, Gen. Grant was appointed secretary of war *ad interim* in place of Mr. Stanton, suspended. When congress assembled in December, the president sent to the senate his reasons for the suspension, which that body did not approve; and thereupon in January, 1868, Gen. Grant surrendered the office to Mr. Stanton. On Feb. 21 the president issued an order removing Mr. Stanton from office and designating Gen. Lorenzo Thomas secretary of war *ad interim;* but as the senate had passed a resolution that the president did not possess the power of removal, Mr. Stanton refused to surrender the office. On the 24th a resolution for the impeachment of President Johnson was adopted by the house of representatives, and articles were subsequently drawn up charging him with high misdemeanors in office in the removal of Stanton and appointment of Thomas, and in attempting to bring congress into contempt and reproach. He was tried before the senate and acquitted in May, there being a majority against him, but not the necessary two-thirds vote. (See JOHNSON, ANDREW.) Secretary Stanton thereupon resigned, and was succeeded by Gen. John M. Schofield. In July Mr. Stanbery was succeeded by William M. Evarts of New York as attorney general. One new state, Nebraska, was admitted during Mr. Johnson's administration, in February, 1867; and in the same year Alaska was purchased of Russia. On Feb.

22, 1868, a naturalization treaty was concluded with the North German confederation. The national republican convention assembled at Chicago on May 21, 1868, and nominated Gen. Ulysses S. Grant for president, and for vice president Schuyler Colfax of Indiana. The platform congratulated the country on the success of the reconstruction policy of congress; denounced all forms of repudiation as a national crime; declared that "the national honor requires the payment of the public indebtedness in the uttermost good faith to all creditors at home and abroad, not only according to the letter, but the spirit of the laws under which it was contracted;" and that "the guaranty by congress of equal suffrage to all loyal men at the south was demanded by every consideration of public safety, of gratitude, and of justice, and must be maintained; while the question of suffrage in all the loyal states properly belongs to the people of those states." The national democratic convention assembled at New York on July 4, and nominated Horatio Seymour of New York for president and Francis P. Blair, jr., of Missouri, for vice president. The platform recognized the settlement of the questions of slavery and secession by the war or the voluntary action of the southern states; demanded the "immediate restoration of all the states to their rights in the Union under the constitution," "amnesty for all political offences and the regulation of the elective franchise in the states by their citizens," and "the abolition of the freedmen's bureau and all political instrumentalities designed to secure negro supremacy;" denounced the reconstruction acts of congress "as usurpations and unconstitutional, revolutionary, and void;" arraigned the republican party because, "instead of restoring the Union, it has, so far as in its power, dissolved it, and subjected ten states, in time of profound peace, to military despotism and negro supremacy;" and declared that "where the obligations of the government do not expressly state upon their face, or the law under which they were issued does not provide, that they shall be paid in coin, they ought, in right and in justice, to be paid in the lawful money of the United States." The election took place on Nov. 3, Virginia, Mississippi, and Texas not voting. Seymour and Blair received the electoral votes of New York, New Jersey, Delaware, Maryland, Georgia, Louisiana, Kentucky, and Oregon, 80; Grant and Colfax received those of all the other states, 214, and were elected. The total popular vote was 5,716,788, of which 3,013,188 were for the Grant electors and 2,703,600 for the Seymour electors. This was the first presidential election in which any considerable number of colored voters participated. (See GRANT, ULYSSES S.) In 1872 President Grant was reëlected. On May 1 of that year a convention assembled at Cincinnati, composed of persons previously in sympathy with the republican party, but now dissatisfied with the administration of President Grant and opposed to his reëlection. They styled themselves "liberal republicans." By this convention Horace Greeley of New York was nominated for president, and Benjamin Gratz Brown of Missouri for vice president. The platform opposed any reopening of the questions settled by the thirteenth, fourteenth, and fifteenth amendments of the constitution, and the candidacy of any president for reëlection; demanded the immediate and absolute removal of all disabilities imposed on account of the rebellion, a thorough reform of the civil service as one of the most pressing necessities of the hour, and a speedy return to specie payments; denounced repudiation in every form and guise; and declared that "local self-government, with impartial suffrage, will guard the rights of all citizens more securely than any centralized power." The national republican convention assembled at Philadelphia on June 5, and nominated President Grant for reëlection, and for vice president Henry Wilson of Massachusetts. The platform, appealing to the history of the party, recited that it had suppressed a gigantic rebellion, emancipated 4,000,000 slaves, decreed the equal citizenship of all, established universal suffrage, and, with unparalleled magnanimity, had punished no man for political offences; approved the action of congress in extending amnesty to those lately in rebellion; favored reform in the civil service; denounced repudiation of the public debt, in any form or disguise, as a national crime; announced a confident expectation of a speedy resumption of specie payment; declared that "the recent amendments to the national constitution should be cordially sustained because they are right, not merely tolerated because they are law, and should be carried out according to their spirit by appropriate legislation, the enforcement of which can safely be intrusted only to the party that secured those amendments;" that "neither the law nor its administration should admit any discrimination in respect of citizens by reason of race, creed, color, or previous condition of servitude;" and that "congress and the president have only fulfilled an imperative duty in their measures for the suppression of violent and treasonable organizations in certain lately rebellious regions, and for the protection of the ballot box." The national democratic convention assembled at Baltimore on July 9, and nominated the same candidates and adopted the same platform as the Cincinnati convention. On Sept. 3 a convention of "straight-out" democrats, opposed to the Baltimore nominations and platform, assembled at Louisville, Ky., and nominated Charles O'Conor of New York for president and John Quincy Adams of Massachusetts for vice president. Conventions were also held and nominations made by the "labor reform" and "temperance" parties. The candidates of the former declined, and no ticket was put in the field; the candidates of the latter were, for president James

Black of Pennsylvania, for vice president John Russell of Michigan. The election, which took place on Nov. 5, resulted in the choice of Grant and Wilson, who each received 286 electoral votes. Greeley having died prior to the choice of president by the electors, the 66 votes of the opposition were given to various persons. Grant and Wilson received a majority of the popular vote in all the states except Georgia, Kentucky, Maryland, Missouri, Tennessee, and Texas, which voted for Greeley and Brown, and Louisiana, where the result was in dispute, two returns being made, one in favor of either party, both claimed to be legal and correct. No electoral votes were counted from Louisiana, nor from Arkansas (owing to certain irregularities), those states together being entitled to 14 votes. The popular vote, excluding Louisiana, which cast about 125,000 votes, was 6,337,662, of which 3,525,469 were for Grant, 2,777,096 for Greeley, 29,489 for O'Conor, and 5,608 for Black. The inauguration took place on March 4, 1873, and the cabinet was constituted as follows, the only change being in the secretary of the treasury: Hamilton Fish, secretary of state; William M. Richardson of Massachusetts, of the treasury; William W. Belknap, of war; George M. Robeson, of the navy; Columbus Delano, of the interior; George H. Williams, attorney general; and John A. J. Creswell, postmaster general. In 1874 Mr. Richardson was succeeded by Benjamin H. Bristow of Kentucky, and Mr. Creswell by Marshall Jewell of Connecticut; in 1875 Mr. Delano was succeeded by Zachariah Chandler of Michigan and Mr. Williams by Edwards Pierrepont of New York; and in 1876 Mr. Belknap was succeeded by Alphonso Taft of Ohio. In 1869 the Central and Union Pacific railroads were completed, opening a highway between the Atlantic and Pacific coasts. One of the most prominent events of Grant's administration is the settlement of outstanding disputes with Great Britain, of which the principal related to the charge that the British government had failed in its duties as a neutral in allowing the construction and fitting out of confederate cruisers in British ports. The claims for damages on this account are known as the "Alabama claims." After protracted correspondence it was agreed to appoint a joint high commission to negotiate a treaty. The commissioners on the part of the United States were Hamilton Fish, secretary of state; Samuel Nelson, associate justice of the supreme court; Robert C. Schenck, then minister to England; E. R. Hoar, late attorney general; and George H. Williams, then United States senator. Those on the part of Great Britain were Earl de Grey (now marquis of Ripon), Baron Grantham, Sir Stafford Henry Northcote, Sir Edward Thornton, Sir John Alexander Macdonald, and Montague Bernard. The commissioners assembled in Washington, Feb. 27, 1871, and on May 8 signed the treaty of Washington, the ratifications of which were exchanged at London on June 17. The treaty provided for the settlement of the Alabama claims by a tribunal of arbitration to meet at Geneva, Switzerland, and to be composed of five arbitrators, appointed one each by the president, the queen, the king of Italy, the president of the Swiss confederation, and the emperor of Brazil. Other claims of American citizens against the British government and of British subjects against the United States arising out of acts committed between April 13, 1861, and April 9, 1865, were to be referred to three commissioners, appointed, one by the president, one by the queen, and one by the two jointly, to meet in Washington. The conflicting claims of the two nations, growing out of the treaty of June 15, 1846, to San Juan and other islands between Washington territory and Vancouver island, were referred to the arbitration of the emperor of Germany. The treaty also contained certain stipulations respecting the navigation of rivers, lakes, and canals adjacent to the United States and Canada, and respecting the transit of goods through those countries, and provisions respecting the coast fisheries. (See FISHERIES, vol. vii., p. 231.) Three commissioners, to sit at Halifax, Nova Scotia, and to be appointed, one by the president, one by the queen, and one by the two jointly, were provided for the determination of the claim of Great Britain to compensation for the rights of fishery granted by her. The Geneva tribunal was composed of the following arbitrators: Charles Francis Adams, appointed by the United States; Sir Alexander J. E. Cockburn, by Great Britain; Count Paolo Federigo Sclopis de Salerano, by Italy; Jakob Staempfli, by Switzerland; and Marcos Antonio d'Araujo, baron (afterward viscount) d'Itajubá, by Brazil. The tribunal convened on Dec. 15, 1871, the United States being represented by J. C. Bancroft Davis as agent, and Caleb Cushing, William M. Evarts, and Morrison R. Waite as counsel. On Sept. 14, 1872, a decision was rendered that Great Britain had failed in her duties as a neutral in the cases of the Alabama, Florida, Shenandoah, and their tenders, and awarded to the United States the sum of $15,500,000 in gold. This sum was promptly paid by Great Britain, and a commission, appointed under an act of congress, is now (1876) in session in Washington determining the rights of individual claimants. The San Juan question was decided in favor of the United States by the German emperor on Oct. 21, 1872. (See SAN JUAN.) (See "Papers relating to the Treaty of Washington," published by the department of state, 5 vols., 1872.) The Washington commission was composed of James S. Frazer, appointed by the United States; Russell Gurney, by Great Britain; and Count Corti, Italian minister at Washington, by the two jointly. It assembled Sept. 26, 1871, and adjourned Sept. 25, 1873, after making an award against the United States of $1,929,819. The Halifax commission has not yet (1876) been organized. For a notice of the negotiations respecting the annexation of Santo Domingo (1869–'71), see Grant, Ulysses S., vol. viii., p. 160. Since the outbreak of the Cuban rebellion, the relations between Spain and the United States have frequently been disturbed. The capture of the steamer Virginius on the high seas under the United States flag on Oct. 31, 1873, by the Spanish man-of-war Tornado, for a time threatened war. The Virginius was taken to a Cuban port, and several of those on board were summarily shot on the charge of being connected with the insurrection. On Dec. 16 the steamer was given up to the United States, and two days after the survivors of those on board were surrendered. In the spring of 1875 Spain paid the United States $80,000 for the relief of the families of those executed. In 1868 a secret organization, known as the Ku-Klux Klan, made its appearance in the south, and numerous outrages were committed by its members on colored citizens and others who favored the congressional plan of reconstruction. On April 20, 1871, congress passed an act to enforce the provisions of the fourteenth amendment, by which cognizance of these offences was given to the United States courts, and several convictions were had under its provisions. On May 31, 1870, an act had been passed (amended Feb. 28, 1871) to enforce the provisions of the fifteenth amendment, the design of which was to protect colored citizens in their right to vote. An act of March 1, 1875, prohibited the denial of equal rights in inns, public conveyances, theatres, &c., to any one on account of race, color, or previous condition of servitude. (See Census, vol. iv., p. 797.)—The following is a list of the presidents and vice presidents, to the date of this volume:

PRESIDENTS.	States of which citizens.	Terms.
George Washington	Virginia	April 30, 1789, to March 4, 1797.
John Adams	Massachusetts	March 4, 1797, to March 4, 1801.
Thomas Jefferson	Virginia	March 4, 1801, to March 4, 1809.
James Madison	Virginia	March 4, 1809, to March 4, 1817.
James Monroe	Virginia	March 4, 1817, to March 4, 1825.
John Quincy Adams	Massachusetts	March 4, 1825, to March 4, 1829.
Andrew Jackson	Tennessee	March 4, 1829, to March 4, 1837.
Martin Van Buren	New York	March 4, 1837, to March 4, 1841.
William Henry Harrison*	Ohio	March 4, 1841, to April 4, 1841.
John Tyler	Virginia	April 4, 1841, to March 4, 1845.
James Knox Polk	Tennessee	March 4, 1845, to March 4, 1849.
Zachary Taylor*	Louisiana	March 4, 1849, to July 9, 1850.
Millard Fillmore	New York	July 9, 1850, to March 4, 1853.
Franklin Pierce	New Hampshire	March 4, 1853, to March 4, 1857.
James Buchanan	Pennsylvania	March 4, 1857, to March 4, 1861.
Abraham Lincoln*	Illinois	March 4, 1861, to April 15, 1865.
Andrew Johnson	Tennessee	April 15, 1865, to March 4, 1869.
Ulysses S. Grant	Illinois	March 4, 1869, to March 4, 1877.
Rutherford Birchard Hayes	Ohio	March 5, 1877, to March 4, 1881.
James Abram Garfield*	Ohio	March 4, 1881, to Sept. 19, 1881.
Chester Alan Arthur	New York	Sept. 19, 1881, to March 4, 1885.
VICE PRESIDENTS.		
John Adams	Massachusetts	April 21, 1789, to March 4, 1797.
Thomas Jefferson	Virginia	March 4, 1797, to March 4, 1801.
Aaron Burr	New York	March 4, 1801, to March 4, 1805.
George Clinton*	New York	March 4, 1805, to April 20, 1812.
Elbridge Gerry*	Massachusetts	March 4, 1813, to Nov. 23, 1814.
Daniel D. Tompkins	New York	March 4, 1817, to March 4, 1825.
John Caldwell Calhoun†	South Carolina	March 4, 1825, to Dec. 28, 1832.
Martin Van Buren	New York	March 4, 1833, to March 4, 1837.
Richard Mentor Johnson	Kentucky	March 4, 1837, to March 4, 1841.
John Tyler	Virginia	March 4, 1841, to April 4, 1841.
George Mifflin Dallas	Pennsylvania	March 4, 1845, to March 4, 1849.
Millard Fillmore	New York	March 4, 1849, to July 9, 1850.
William Rufus King*	Alabama	March 4, 1853, to April 18, 1853.
John Cabell Breckinridge	Kentucky	March 4, 1857, to March 4, 1861.
Hannibal Hamlin	Maine	March 4, 1861, to March 4, 1865.
Andrew Johnson	Tennessee	March 4, 1865, to April 15, 1865.
Schuyler Colfax	Indiana	March 4, 1869, to March 4, 1873.
Henry Wilson*	Massachusetts	March 4, 1873, to Nov. 22, 1875.
William Almon Wheeler	New York	March 5, 1877, to March 4, 1881.
Chester Alan Arthur	New York	March 4, 1881, to Sept. 19, 1881.

The chief justices have been as follows: John Jay of New York, Sept. 26, 1789, to June 29, 1795; John Rutledge of South Carolina, July 1, 1795, to Dec. 15, 1795 (appointed in the recess of the senate, presided at the August term, rejected by the senate); Oliver Ellsworth of Connecticut, March 4, 1796, to October. 1800; John Marshall of Virginia, Jan. 31, 1801, to July 6, 1835; Roger Brooke Taney of Maryland, March 15, 1836, to Oct. 12, 1864; Salmon Portland Chase of Ohio, Dec. 6, 1864, to May 7, 1873; and Morrison Remich Waite of Ohio, appointed Jan. 21, 1874. William Cushing of Massachusetts, appointed Jan. 27, 1796, and John Jay, reappointed Dec. 19, 1800, declined.

UNITED STATES, Literature of the. The literary history of the United States may be treated under three distinctly marked periods, viz., a colonial or ante-revolutionary period (1620–1775), during which the literature of the country was closely assimilated in form and character to that of England; a first American period (1775–1820), which witnessed the transition from a style for the most part imitative to one in some degree national; and a second American (from 1820 to the present time), in which the literature of the country assumed a decided character of originality. I. 1620–1775. The first literary production of any note in the British American colonies was the version of Ovid's "Metamorphoses" made by George Sandys in Virginia about 1620 (London, 1626). But though men of letters were found everywhere among the early colonists, in New England alone, where in 1639 the first printing press was established in Cambridge, was any considerable progress in literary culture made, and the literature of the first or colonial period was chiefly confined to that locality or was indirectly connected with it. The earliest development was theological. The "Bay Psalm Book" (Cambridge, 1640), the first book printed in the country, though not strictly original, became very popular both in America and Great Britain, and within a little more than a century passed through 70 editions. Ten years later a volume of poems by Mrs. Anne Bradstreet of Massachusetts (1612–'72), entitled "The Tenth Muse lately sprung up in America," was published in London, and reprinted in Boston with additions in 1678. "The simple Cobler of Agawam," a quaint satire by Nathaniel Ward, pastor of the church at Ipswich, Mass., was written there in 1645 and published in London in 1647, after the author's return to England. The most remarkable early productions of the colonial press were the Indian Bible of John Eliot (1604–'90), the first edition of the Scriptures published in America (Cambridge, 1661–'3), and an extraordinary monument of patience and industry, though now of interest only to the antiquary; the "Concordance of the Scriptures," by John Newman, which was the earliest work of its kind, and the immediate precursor of Cruden's Concordance; and the prolific writings of Increase and Cotton Mather, the latter of whom (1663–1728) was the author of 382 works, of most of which not even the titles are remembered; the most celebrated are the "Wonders of the Invisible World" and the *Magnalia Christi Americana*, an ecclesiastical history of New England from 1620 to 1698, containing biographies of several colonial worthies. To the early colonial times also belong John Cotton (1585–1652), one of the first ministers of Boston; Thomas Hooker (1586–1647); Roger Williams (1606–'83), the founder of Rhode Island; John Davenport (1598–1670), Charles Chauncy (1592–1672), and John Norton (1606–'63), eminent in their day as theological writers, but whose works are now little known. The establishment of Harvard college in 1636, and of William and Mary and Yale colleges in the last decade of the 17th century, and the practice which became common with many of the wealthier colonists of sending their sons to England to be educated, showed their effects in the gradual improvement of style and in the more discursive aims of writers. A Virginia gentleman, Col. William Byrd (1674–1744), wrote an interesting narrative of a journey made in 1728 and other sketches of travel in Virginia, published as "The Westover Manuscripts" in 1841. But theology was still the department of letters most generally cultivated, and among theologians Jonathan Edwards (1703–'58), whose power of subtle argument Sir James Mackintosh declares to be "perhaps unmatched, certainly unsurpassed among men," was the first not only in America, but, according to Robert Hall, in "any country or age." His celebrated treatise on the "Freedom of the Will" ranks among the standard authorities in English metaphysics; and his other works exhibit a force of thought and keenness of argument only displayed by the greatest minds. Other theologians of the colonial period were a second Charles Chauncy (1705–'87); James Blair (1656–1743), president of William and Mary college; Jonathan Mayhew (1720–'66), a vigorous opponent of episcopacy and a man of liberal political views; Samuel Johnson (1696–1772), the first president of Columbia college, and the father of the American Episcopal church; John Witherspoon (1722–'94); and Ezra Stiles (1727–'95), president of Yale college. John Woolman (1720–'72), a Quaker writer and preacher, deserves mention as one of the first who wrote against slavery. The influence of the great English essayists and novelists of the 18th century had meanwhile begun to affect the literature of the new world; and in the essays, the collection of maxims published under the title of "Poor Richard," the scientific papers, and the autobiography of Benjamin Franklin (1706–'90), we have specimens of practical philosophy or of simple narrative, expressed in a style eminently clear, pleasing, and condensed, and not unfrequently embellished by the wit and elegance characteristic of the best writers of Queen Anne's time. His investigations in electricity and other scientific subjects are not less felicitously narrated, and, together with the works of James Logan (1674–1751), Paul Dudley (1675–1751), Cadwallader Colden (1688–1776), and John Bartram, a naturalist and one of the earliest of American travellers (1701–'77), constitute the chief contributions to scientific literature during the colonial period. The historians and annalists are less prominent than the theologians; but the tracts and pamphlets relating to the discovery and colonization of British America, written by early settlers, are exceedingly numerous, and the journals and annals of Winthrop, Winslow, Morton, and others are worthy of note as being the sources from which modern historical writers have derived much important information. William Hubbard (1621–1704) wrote a history of New England, which was not published until more than a century after his death; and Thomas Prince (1687–1758) began a more extensive work on the same subject, which was never completed. Among the earlier contributions to American local history are the "History of the Present State of Virginia," by Robert Beverley (London, 1705), that of the discovery and settlement of Virginia by William Stith (died 1750), and that of Massachusetts by Thomas Hutchinson, its last colonial governor, a man of considerable learning and culture. Of works relating to the Indians, the most noteworthy were the history of King Philip's war by the famous Capt. Benjamin Church (1639–1718), the history of the Five Nations by Cadwallader Colden, and the "Diary" of the missionary David Brainerd (1718–'47). The poetry of this period has no pretension to literary merit, but the drama of "The Prince of Parthia," by Thomas Godfrey, a son of the inventor of the mariners' quadrant, deserves mention as the first work of the class produced in America. II. 1775–1820. The earliest works produced during the first American period, beginning with the revolution, are naturally associated with the causes which led to that event; and the political pamphlets, speeches, letters, and other writings of the men who aided in securing the independence of the North American colonies afford the first indications of a desire to cast aside the conventionalisms of European literature, and to develop one characteristic of the country and its institutions. The severance of the intellectual reliance of the colonies upon the mother country followed as a consequence of their political independence, and as early as the commencement of the revolutionary struggle the high literary ability and practical wisdom evinced in the public documents of the principal American statesmen were recognized by Lord Chatham, who praised them as rivalling the masterpieces of antiquity. Politics now gained a prominence almost equal to that enjoyed by theology in the preceding period; and dry as such subjects usually are to the mass of readers, the discussion of them in speeches and pamphlets during the last quarter of the 18th century accorded thoroughly with the popular taste, and the influence of political writers and orators in giving a decided national type to American literature is unmistakable. Conspicuous among the early pamphleteers were James Otis (1725–'83), Josiah Quincy, jr. (1744–'75), John Dickinson (1732–1808), Joseph Galloway, a tory writer (1730–1803), Richard Henry Lee (1732–'94), Arthur Lee (1740–'92), William Livingston (1723–'90), William Henry Drayton (1742–'99), John Adams (1735–1826), Thomas Jefferson (1743–1826), and Timothy Pickering (1745–1829), of whom Otis and Quincy were perhaps most distinguished as orators, although little beyond the traditions of their eloquence has come down to us. For fervid declamation Patrick Henry (1736–'99) stands at the head of all the orators of this period; and in the reports of his speeches, meagre as they are, he has been more fortunate than others of his contemporaries, as Samuel Adams (1722–1803), Christopher Gadsden (1724–1805), John Rutledge (1739–1800), Edward Rutledge (1749–1800), Charles Cotesworth Pinckney (1746–1825), Gouverneur Morris (1752–1816), and George Mason (1726–'92), whose reputation as parliamentary debaters or public speakers was very high. The "Common Sense" of Thomas Paine (1737–1809), though not strictly the work of an American author, may be classed with the early national literature, from the fact that it was thoroughly American in tone, and was inspired by the causes which produced the revolution. The great state paper of this era was the "Declaration of Independence," by Thomas Jefferson, which may be considered unrivalled among works of its class. (See UNITED STATES, p. 157.) Jefferson also published a "Summary View of the Rights of British America," and "Notes on Virginia," which passed through many editions in Europe and America, and left a mass of correspondence forming a valuable contribution to American political history. The writings of George Washington (1732–'99) must always hold a distinguished place in American literature, not only for their lofty patriotism and solid common sense, but for their clearness of expression and force of language; a characteristic, indeed, of most of the writers who were contemporary with him. Alexander Hamilton (1757–1804), by turns soldier, lawyer, and statesman, was a member of the convention which framed the federal constitution; and according to Guizot there is not "one element of order, strength, or durability" in that instrument which he did not powerfully contribute to introduce. An enduring monument of his political sagacity and literary ability is the "Federalist," a series of papers written chiefly by himself for the purpose of elucidating and supporting the principles of the new constitution. Hamilton was assisted in this work by John Jay (1745–1829), the first chief justice of the United States, and James Madison (1751–1836), the fourth president, of whom the former was the author of an "Address to the People of Great Britain" issued by congress in 1774, and other political papers, and the latter a prolific writer on political, constitutional, and historical subjects. John Adams, who wrote with perspicuity and elegance, published a "Defence of the American Constitution," and a series of "Discourses on Davila," directed against the French revolutionary ideas prevalent in the last decade of the 18th century, and left numerous political papers and letters, which, together with his "Diary," begun in 1755, have been edited by his grandson Charles Francis Adams. The most accomplished rhetorician and speaker of the period was Fisher Ames (1758–1808), whose essays and orations are distinguished by a splendor of diction which often wearies the reader, notwithstanding the felicity of the metaphors and illustrations. His reputation, owing to the temporary interest of many of the subjects on which he wrote and spoke, has very much declined. —The historians and biographers of this period creditably illustrate the growing literature of the country, and several of their productions are still regarded as standard authorities. Among special local histories are those of New Hampshire by Jeremy Belknap (1744–'98), whose series of "American Biographical Sketches" were the precursors of the valuable works of Sparks; of Connecticut by Benjamin Trumbull (1735–1820); of Massachusetts by George R. Minot (1758–1802), being a continuation of that by Hutchinson; of Vermont by Samuel Williams (1761–1818); and of Pennsylvania by Robert Proud (1728–1813). Of more general interest are the histories of New England by Hannah Adams (1755–1832), and of the American revolution by William Gordon (1730–1807), an English clergyman long settled in America, and David Ramsay (1749–1815), who also wrote a history of South Carolina, a life of Washington, and other works, evincing much research and a conscientious spirit of inquiry. The "Annals of America," by Abiel Holmes (1763–1837), has for more than half a century been considered a leading authority in American history. The most important biography produced during this period is the "Life of Washington" by Chief Justice Marshall (1755–1835). William Wirt (1772–1834), an accomplished forensic orator, produced a "Life of Patrick Henry," and also a series of papers entitled "Letters of the British Spy," written with much elegance and force; and the "Military Journal" of Dr. James Thacher (1754–1844), and "Memoirs" of Alexander Graydon (1752–1818), both officers in the American revolutionary army, contain many interesting and trustworthy accounts of the men and times which they illustrate. Of works of travel, the most important are the narrative of Jonathan Carver (1732–'80); the journals of the intrepid John Ledyard (1751–'89); the reports of Major Zebulon Montgomery Pike (1779–1813), the earliest American explorer of the head waters of the Mississippi and the Rio Grande; and the account of the expedition of Lewis and Clarke across the Rocky mountains to the mouth of the Columbia river, prepared by Nicholas Biddle and Paul Allen.—The theologians of this period are ably represented by Jonathan Edwards (1745-1801), son of the great metaphysician of the same name, and the author of a profound "Dissertation on Liberty and Necessity," and of a treatise entitled "The Salvation of all Men Examined and Explained;" Samuel Hopkins (1721–1803), whose "System of Theology" presents a reflex of the progress of religious opinions in New England; Timothy Dwight (1752–1817), president of Yale college, whose principal work, "Theology Explained and Defended," maintains moderate Calvinistic views with much dignity and eloquence, and has been extensively circulated in England and America; and Bishop William White (1747–1836), the earliest historian of the Protestant Episcopal church in America. Other eminent clergymen and authors were Joseph Bellamy (1719–'90), John Smalley (1734–1820), Nathanael Emmons (1745–1840), John Mitchell Mason (1770–1829), Noah Worcester (1758–1838), Samuel Worcester (1771–1821), Edward Payson (1783–1827), Bishops John Henry Hobart (1775–1830) and Theodore Dehon (1776–1817), and John Murray (1741–1815), the father of Universalism in America. Prominent among the younger theologians was Joseph Stevens Buckminster (1784-1812), one of the earliest of the New England Unitarians, whose published sermons are remarkable for purity of thought and finish of style.—One of the first and most useful laborers in the field of science was David Rittenhouse (1732–'96), a great and self-educated genius, whose memoirs on astronomy and mathematics were published in the first four volumes of the "Transactions" of the philosophical society of Philadelphia. Benjamin Rush (1745–1813) and James McClurg (1747–1825) were conspicuous as writers on medical science, the work of the former on the "Diseases of the Mind" being still a standard authority; and Benjamin Smith Barton (1766–1815), a naturalist, produced the first American elementary work on botany, and the first contribution to the ethnographical literature of the country. The most important contribution to natural history was the "Description of the Birds of North America," by Alexander Wilson (1766–1813). Samuel Latham Mitchill (1764–1831) was one of the earliest writers on chemistry, and made valuable contributions also to zoölogy and botany. To these names may be added those of Lindley Murray (1745–1826), author of the well known "English Grammar" bearing his name, and the eminent physicist Benjamin Thompson, Count Rumford (1753–1814), both of whom were Americans by birth and education.—The most distinguished poet of this period was Philip Freneau (1752–1832), many of whose productions, inspired by the revolutionary spirit, display vigor of language and considerable imaginative power. Contemporary with him were John Trumbull (1750–1831), author of a once popular poem in the Hudibrastic style entitled "McFingal," in which the tories and other enemies to American liberty are satirized, and which presents a remarkably vivid picture of contemporary manners and opinions; Joel Barlow (1755–1812), who wrote a heavy epic entitled "The Columbiad," which was well received, and was reprinted in London and Paris, and a humorous mock-heroic poem in praise of "Hasty Pudding;" Lemuel Hopkins (1750–1801), author of a satirical poem called "The Anarchiad;" and Timothy Dwight, the theologian, whose "Conquest of Canaan" and other poems exercised considerable influence upon contemporary writers. William Clifton (1772–'99) wrote a few songs equal to any poetry which had appeared in America; and Thomas Green Fessenden (1771–1837) produced in London a very successful satire entitled "The Terrible Tractoration." Among the other poets of the period were David Humphreys (1752–1818), Joseph Hopkinson (1770–1842), author of "Hail Columbia," and Robert Treat Paine, jr. (1773–1811), whose "Adams and Liberty" was once a rallying song of the federalists. The style adopted by these writers was essentially that prevalent in England during the latter half of the 18th century; nor was any innovation upon established models, whether in form or expression, attempted in American poetry until after the commencement of the third period of the national literature.—Charles Brockden Brown (1771–1810), the first American novelist, was also the first author who made a profession of literature; his best productions, "Wieland, or the Transformation," "Arthur Mervyn," and "Edgar Huntley," have much graphic power and are good specimens of the Godwin school of fiction.—Of the miscellaneous writers of the period, whose productions appeared mostly in the newspapers and magazines, the chief were Francis Hopkinson (1737–'91), eminent as a humorous writer in prose and verse; Hugh Henry Brackenridge (1748–1816), author of a vigorous satire entitled "Modern Chivalry;" Joseph Dennie (1768–1812), one of the earliest American magazine writers and editors, who published a well known series of essays under the title of "The Lay Preacher;" David Everett (1769–1813), Isaac Story (1774–1803), Paul Allen (1775–1826), and Royall Tyler (1757–1826). Tyler was a wit, a poet, and chief justice of Vermont. His play "The Contrast," produced on the stage in New York in 1786, was the first in which the conventional Yankee dialect was used. He wrote also a successful novel called "The Algerine Captive." III. 1820–1876. The last period in American literature presents a marked contrast to those which preceded, in the national character as well as in the variety and extent of its productions. It was in 1820 that the poverty of American literature was sneeringly commented upon by Sydney Smith in an article in the "Edinburgh Review;" and from that date the intellectual development of the country, the political crisis which attended the establishment of the government being past, has been commensurate with its social and material progress, until at the present day there is no department of human knowledge which has not been explored by American authors. In history, in jurisprudence, and in certain departments of natural science and imaginative literature, many of their productions during the last 50 years deserve to be ranked among the best in the universal literature of the age. Within this period the style and tone of the national literature have begun to partake more decidedly of the national character, although in certain departments only, particularly in that of imaginative writing, has any decided originality been shown.—While in the periods already treated of, the labors of American historians were for the most part confined to the collection of materials or to the unadorned record of facts, their successors have taken a wider range of subjects, and infused a more philosophical spirit into their writings; and although, among the many hundred historical works already produced, few rise above the dignity of local narratives or compilations of materials, as storehouses of data they have been ably employed by those who can analyze the significance of events. Prominent among these is George Bancroft (born 1800), whose "History of the United States" has been pronounced "the most successful attempt yet made to reduce the chaotic but rich materials of American history to order, beauty, and moral significance." It is characterized by an earnest sympathy with democratic institutions, by a generous enthusiasm for the martyrs of freedom and civilization, by patient research and discrimination in the choice of authorities, and by a style animated and genial, although in occasional passages perhaps somewhat too labored. The work brings the history down to the close of the revolution, and the author, it is understood, proposes to continue it to a much later period. He has revised the ten volumes already issued and republished them in a "centenary" edition in six volumes (1876). The same subject has been ably treated by Richard Hildreth (1807–'65), whose work, bringing the narrative down to 1821, though written with no special attempt at rhetorical grace or picturesque effect, is valuable for its general accuracy, and has become a standard book of reference. Among the most successful of the writers of American history is Francis Parkman (born 1823), who has devoted himself to narrating the rise and fall of the French dominion in America. His "Pioneers of France," "Jesuits in North America," "Discovery of the Great West," "Old Régime in Canada," and "Conspiracy of Pontiac," form a series of the highest value, distinguished for accurate research, for brilliant style, and for profound knowledge of Indian character and manners, acquired by personal observation of the red man among the wildest tribes. Many school histories of the United States have been written, of which those by Salma Hale, S. G. Goodrich ("Peter Parley," 1793–1860), Samuel Eliot, Emma Willard, Benson J. Lossing, Marcius Willson, G. P. Quackenbos, J. J. Anderson, William Swinton, A. H. Stephens, G. F. Holmes, T. W. Higginson, Edward Abbott, and Abby S. Richardson may be cited. Intermediate between the school histories and the larger works are the compendious volume of J. H. Patton, which brings the narrative down to the beginning of the civil war, and "The Popular History of the United States," by W. C. Bryant and S. H. Gay, which is written with animation and is profusely illustrated. Among works illustrating particular periods or passages in the general history of the country may be mentioned the "Pictorial Field Book of the Revolution" and "Pictorial Field Book of the War of 1812," by B. J. Lossing; the "History of the United States Navy," by James Fenimore Cooper; histories of the war of 1812 by C. J. Ingersoll (1782–1862) and Lossing; the "American Archives" and other works by Peter Force; "Our First Hundred Years" (1874 *et seq.*), by C. Edwards Lester; and numerous minor productions by W. L. Stone (1792–1844), John Armstrong, W. H. Trescot, Brantz Mayer, Winthrop Sargent, Richard Frothingham, jr., J. T. Headley, J. Sprague, Frank Moore, and others. The war of 1861–'5 has given rise to a large class of works, most of them necessarily ephemeral, but some of which deserve special mention as histories or sources of history. Prominent among these are "The Rebellion Record" (1861–'71), edited by Frank Moore, a vast collection of documents in 12 volumes; "Reports of the Congressional Committee on the Conduct of the War;" "Annals of the United States Christian Commission," by Lemuel Moss; "The American Conflict," by Horace Greeley; "History of the American Civil War," by J. W. Draper; "History of the Rise and Fall of the Slave Power in America," by Vice President Henry Wilson; "The Campaigns of the Army of the Potomac" and "The Twelve Decisive Battles of the War," by William Swinton; "Report of the Army of the Potomac," by Gen. George B. McClellan; and "Memoirs of Gen. William T. Sherman, by Himself." All of these represent the Union side of the conflict, while on the confederate side the following are the principal works: "The War between the States," by A. H. Stephens; "History of the War of Secession," by J. F. H. Claiborne; "Southern History of the War" and "The Lost Cause," by E. A. Pollard; "Narrative of Military Operations," by Gen. Joseph E. Johnston; "Personal Reminiscences" of Lee, by J. W. Jones; lives of Lee and of "Stonewall" Jackson, by J. Esten Cooke; and various books by Alfriend, Howiston, H. A. Wise, G. C. Eggleston, and others. The list of histories of single states or groups of states, of special territorial districts, or of institutions, presents many works of merit. At the head of these perhaps stands the "History of New England," by J. G. Palfrey (born 1796), of which four volumes, embracing the events previous to 1741, have been published. The subject is treated with more fulness than in the work of Bancroft, and in a style of singular purity and finish. To this class belong the valuable "Geography and History of the Mississippi Valley" by Timothy Flint (1780–1840), the "History of the Discovery and Exploration of the Mississippi" and other works by J. G. Shea, the "New England History" by C. W. Elliott, those of the New Netherlands by E. B. O'Callaghan, of New York by John Romeyn Brodhead, of Connecticut by Theodore Dwight and by G. H. Hollister, of North Carolina by F. L. Hawks, of Kentucky by Mann Butler, of Louisiana by Charles Gayarré and by F. X. Martin, of Oregon and the N. W. coast of North America by Robert Greenhow, of South Carolina by W. G. Simms, of Texas by H. Yoakum, of Rhode Island by S. G. Arnold, of Virginia by Charles Campbell, of Western Massachusetts by J. G. Holland and by R. R. Howiston, of Delaware by Francis Vincent, of Maryland by James McSherry, of Indiana by J. B. Dillon, of Pennsylvania and New Jersey by J. R. Sypher, of Wisconsin by W. R. Smith, of Kentucky by Lewis Collins, and of Illinois by Alexander Davidson. Of the numerous minor works of this class, the elaborate history of Boston by S. G. Drake, and of Westchester county, N. Y., by Robert Bolton, and that of Harvard university by Josiah Quincy, may be cited as examples. The history of the aboriginal tribes has been ably treated by S. G. Drake, whose "History and Biography of the Indians of North America" was the first attempt at an impartial narrative of the subject, and is a valuable repertory of facts; by T. L. McKenney and James Hall, who published a costly illustrated "History of the Indian Tribes of North America;" by George Catlin; by W. L. Stone; by L. H. Morgan, author of "The League of the Iroquois;" and especially by Henry Rowe Schoolcraft (1793–1864), whose works, although they come perhaps more naturally within the departments of travels and ethnography, evinced a more intimate acquaintance with the history, languages, and customs of the North American aborigines than any others then published. His elaborate "Historical and Statistical Information respecting the History, Condition, and Prospects of the Indian Tribes of the United States," the most considerable work of the class then undertaken, is in 6 vols. 4to. The works relating directly or indirectly to the history of the United States include C. W. Upham's account of the Salem witchcraft in 1692, R. S. Ripley's "War with Mexico," E. D. Mansfield's "Mexican War," G. W. Kendall's "Santa Fé Expedition," and Theodore Irving's "Conquest of Florida." Among American authors whose labors have been prosecuted beyond the limits of local or domestic history, no name stands higher than that of William Hickling Prescott (1796–1859), the historian of the Spanish conquest and civilization in the new world, and one of the most graceful writers of the English language. His histories of the reigns of Ferdinand and Isabella and Philip II. of Spain, and of the "Conquest of Mexico" and the "Conquest of Peru," and his sequel of Robertson's "History of Charles V.," exhibit remarkable depth and accuracy of research, combined with impartiality and soundness of judgment. The style is at the same time so lucid and attractive as frequently to invest the narrative with the charm of fiction. As Prescott was the first to treat adequately the brilliant period of Spanish ascendancy, so the revolt of the Spanish provinces of the Netherlands and their history as a free Protestant commonwealth have afforded a congenial subject to John Lothrop Motley (born 1814), whose "Rise of the Dutch Republic," "History of the United Netherlands" (a continuation of the former), and "Life and Death of John of Barneveld" display extensive research, and are written with animation, and occasionally with great picturesque beauty. His works have taken their place among the great histories of the time, and have been translated into the principal languages of Europe. Among other writers of foreign history are Henry Wheaton, author of a "History of the Northmen;" Archibald Alexander, author of a "History of the Colonization of the West Coast of Africa;" Brantz Mayer, J. R. Poinsett, and R. A. Wilson, who have written on Mexico; Parke Godwin, who has published the first volume of a comprehensive "History of France;" J. F. Kirk, author of an elaborate history of Charles the Bold; C. C. Felton (1807–'62), who edited Smith's "History of Greece" and wrote a valuable work on "Greece, Ancient and Modern;" G. M. Towle, author of a history of Henry V. of England; John Lord, D. O. Allen, A. L. Koeppen, J. J. Jarves, Edmund Flagg, W. H. Stiles, and G. W. Greene. Many excellent works in the department of ecclesiastical or religious history have also been produced, prominent among which are the "Annals of the American Pulpit," by W. B. Sprague; "History of the Presbyterian Church," by Charles Hodge, and also by E. H. Gillett; "History of the Apostolic Church," by Philip Schaff; "Progress of Religious Ideas," by Mrs. Lydia Maria Child; "The Ten Great Religions," by James Freeman Clarke; "The Oriental Religions," by Samuel Johnson; "History of Methodism," by Abel Stevens; "Modern History of Universalism," by Thomas Whittemore; "Post-Biblical History of the Jews," by M. J. Raphall; "Ecclesiastical History of New England," by J. B. Felt; the contributions to the history of the Protestant Episcopal church in Virginia, by Bishop William Meade and F. L. Hawks; the "History of the Baptist Denomination," by D. Benedict; "The English Bible, a History of the Translation of the Holy Scriptures into the English Tongue," by Mrs. H. C. Conant; and various works by Archibald Alexander, James Murdock, S. F. Jarvis, Robert Baird, Thomas Gaillard, W. Ingraham Kip, John Dowling, J. A. Spencer, Robert Davidson, S. J. Baird, W. E. Schenck, W. G. T. Shedd, H. B. Smith, C. P. Krauth, and many others. To the department of literary history, the most important contributions are the "History of Spanish Literature," by George Ticknor, esteemed the best work on the subject extant; the several works of R. W. Griswold on the "Prose Writers," the "Poets," and the "Female Poets" of America; Caroline May's "American Female Poets;" J. S. Hart's "Female Poets of America," and his "Manuals" of English and American literature; T. Buchanan Read's "Female Poets of America;" Mrs. A. C. L. Botta's "Handbook of Universal Literature;" C. D. Cleveland's compendiums of English, American, and classical literature; C. A. Dana's "Household Book of Poetry;" W. T. Coggeshall's "Poets and Poetry of the West;" J. Wood Davidson's "Living Writers of the South;" Whittier's "Three Centuries of Song;" A. C. Kendrick's "Our Poetical Favorites;" and Emerson's "Parnassus." In this category may properly be placed Wheeler's "Noted Names of Fiction" and the excellent "Familiar Quotations" of John Bartlett. The "Cyclopædia of American Literature," by E. A. and G. L. Duyckinck, is the only comprehensive work on the subject yet published; and the "Critical Dictionary of English Literature," by S. Austin Allibone, forms a valuable epitome of the literary history of England and the United States. Among miscellaneous works are the "History of Civilization," in seven volumes, by Amos Dean; the "History of the Intellectual Development of Europe," by J. W. Draper; and the "History of Liberty," by Samuel Eliot, the completed portion of which, covering the history of the ancient Romans and the early Christians, and the struggle for constitutional liberty in Spain in the 16th century, is written with ability and in a philosophic spirit.—The first in point of date and reputation among the writers of biography of this period is Washington Irving (1783–1859), whose narratives of the "Life and Voyages of Christopher Columbus" and of the "Voyages and Discoveries of the Companions of Columbus," though not the most characteristic of his writings, constitute a permanent contribution to English and American literature. His "Life of George Washington," completed a few months before the author's death, has been more generally read in America than any other of his works. The narrative, embracing necessarily the main incidents of the revolutionary struggle, is related with charming vivacity and great elegance of language. His lives of Mahomet and Goldsmith are pleasing compilations, having little claim to originality. Among the most industrious laborers in the field of American biography is Jared Sparks (1789–1866), who devoted the greater part of his life to studies illustrative of the history of his country, and whose works, written in a sober and correct style, display remarkable diligence of research. The "Library of American Biography," in two series and 25 volumes, edited by him, to which he contributed lives of John Ledyard, Benedict Arnold, Ethan Allen, Charles Lee, Father Marquette, and others, is enriched by contributions from some of the best writers in the country. Mr. Sparks also edited the writings of Washington and Franklin, with lives of each, the diplomatic correspondence of the revolution, and the correspondence of public men with Washington. Of the many biographies of public men produced during this period, the most prominent are those of Josiah Quincy, jr., by his son Josiah Quincy, of Josiah Quincy by his son Edmund Quincy, of Elbridge Gerry by J. T. Austin, of James Otis by William Tudor, of Joseph Reed by his grandson W. B. Reed, of William Wirt by John P. Kennedy, of Thomas Jefferson by George Tucker and by H. S. Randall, of John Adams and John Quincy Adams by Charles Francis Adams, of James Madison by W. C. Rives, of Joseph Story by his son W. W. Story, of Alexander Hamilton by his son J. C. Hamilton, of Timothy Pickering by his son Octavius Pickering (the last 3 vols. by C. W. Upham), of Henry Clay by Calvin Colton, of Aaron Burr, Andrew Jackson, Benjamin Franklin, Thomas Jefferson, Horace Greeley, and B. F. Butler by James Parton, of John P. Kennedy by H. T. Tuckerman, and of Count Rumford by G. E. Ellis, some of which have obtained a wide popularity. Among special biographies of American subjects are the "Life of William Ellery Channing," by his nephew William Henry Channing; the "Memoirs of Margaret Fuller Ossoli," by W. H. Channing, Ralph Waldo Emerson, and James Freeman Clarke; the "Life of Daniel Boone," by Timothy Flint; lives of Marion, Greene, and Captain John Smith, by W. G. Simms; the lives of the Indian chiefs Joseph Brant and Red Jacket, by W. L. Stone; the life of Bishop A. W. Griswold, by J. S. Stone; "Memoir of Rev. Dr. Buckminster and Joseph Stevens Buckminster," by Mrs. Eliza Buckminster Lee; the "Life of Theophilus Parsons," by his son Theophilus Parsons; "Memoirs of Nathanael Emmons," by E. A. Park; the "Life of Washington Irving," by his nephew Pierre M. Irving; of Nathanael Greene, by his grandson, G. W. Greene; of Daniel Webster, by G. T. Curtis; of Abraham Lincoln, by Ward H. Lamon; of Theodore Parker, by John Weiss, and a later and more popular one by O. B. Frothingham; of W. H. Prescott, by George Ticknor; of Fitz-Greene Halleck, by J. G. Wilson; of John Todd, by his son John E. Todd; and John Bigelow's edition of Franklin's autobiography; besides many biographical sketches by Alexander Slidell Mackenzie, G. E. Ellis, Edward and Alexander H. Everett, H. A. Garland, C. C. Felton, C. W. Upham, Henry Wheaton, W. H. Prescott, Henry Reed, G. S. Hillard, William Gammell, J. T. Headley, John Sanderson, R. T. Conrad, C. A. Goodrich, M. L. Davis, Alden Bradford, S. L. Knapp, Nicholas Biddle, Epes Sargent, Richard Frothingham, B. J. Lossing, G. L. Duyckinck, Mrs. L. M. Child, Mrs. E. F. Ellet, and others. To this class also belong such works as the "Lives of American Loyalists," by Lorenzo Sabine; the "Personal Memoirs" of Joseph T. Buckingham; the "Reminiscences" of Bishop Philander Chase; "Recollections of a Busy Life," by Horace Greeley; "Autobiography of Lyman Beecher;" the "Ten Years of Preacher Life" and other works of William Henry Milburn; the "Threading my Way" of Robert Dale Owen; and "The Life, Letters, and Journals" of George Ticknor, edited by G. S. Hillard. The contributors to miscellaneous and foreign biography comprise J. S. C. Abbott, author of a "Life of Napoleon," R. W. Griswold, H. W. Herbert, Samuel Osgood, J. Milton Mackie, Hannah F. Lee, X. Donald McLeod, Alfred Lee, Richard Hildreth, F. L. Hawks, Bishop J. R. Bayley, R. H. Wilde, and many others. Female biography has been comprehensively related by Mrs. S. J. Hale in her "Woman's Record," a sketch of distinguished women in all times. The principal biographical dictionaries are those of William Allen and Francis S. Drake, both devoted to American subjects, and the "Universal Pronouncing Dictionary of Biography and Mythology," by Joseph Thomas, a valuable and comprehensive work; besides which a "Dictionary of Painters, Sculptors, and Engravers" has been published by S. Spooner, a "Cyclopædia of Music" by J. W. Moore, a handbook of painters, sculptors, and other artists by Clara Erskine Clement, and a "Book of the Artists" by Henry T. Tuckerman.—Washington Irving, though not exclusively a writer of prose fiction, was the first American whose fame in this department extended beyond the limits of his native country; and his "Sketch Book," "Knickerbocker's History of New York," "Bracebridge Hall," and "Tales of a Traveller," first introduced to a European public between 1820 and 1830, attracted immediate attention by their imaginative power, by their fine pathos and humor, and by the singularly pure and graceful style in which they were expressed. James Fenimore Cooper (1789–1851) has the credit of giving the first decided impulse to romantic fiction in the new world, and through his works American literature became first generally known abroad. His "Spy," his nautical tales, including "The Pilot" and "The Red Rover," and above all his series of Indian stories, abounding in lively pictures of forest life, took a strong hold upon the popular mind in both hemispheres. He was deficient in some of the requisites of a novelist; but his faculty of description, and quick appreciation of what was tangible and characteristic in his native land, enabled him to gain a universal distinction almost unsurpassed in his field. The success of Cooper gave to the novel of adventure and backwoods life, or that founded upon colonial and revolutionary incidents, a popularity which caused it for a long time to be the chief form of fiction cultivated; and among many meritorious works of this class may be mentioned "The Dutchman's Fireside" and "Westward Ho" of James

---

* Died in office. † Resigned.

Kirke Paulding (1779–1860); "Swallow Barn," "Horse Shoe Robinson," and "Rob of the Bowl," by John Pendleton Kennedy (1795–1870); "Redwood," "Hope Leslie," "The Linwoods," and other pleasing pictures of early American life, by Miss C. M. Sedgwick (1789–1867); "The Partisan," "The Yemassee," "Mellichampe," "Guy Rivers," and numerous other tales by W. G. Simms (1806–'70), one of the most prolific of American authors, who drew largely from the legendary history of the southern states for his materials; "Hobomok" and "The Rebels," by Mrs. L. M. Child (born 1802); "Seventy-Six" and other works by John Neal (born 1793); "A New Home," by Mrs. C. M. Kirkland (1801–'64); the "Nick of the Woods" and other border tales of Dr. Robert M. Bird (1803–'54); and works by Timothy Flint (1780–1840), James Hall (1793–1868), C. F. Hoffman (born 1806), T. B. Thorpe, C. W. Webber, and others. For finish of style, delicacy of psychological insight, and power in delineating the darker features of life and the emotions of guilt and pain, Nathaniel Hawthorne (1804–'64) holds a peculiar place among American novelists. Writing on national subjects, and delighting especially in the gloomy passages of New England colonial history, he employed fiction less for the purpose of illustrating practical life, or of adding to the creations of the imaginative world, than of solving psychological problems. His "Scarlet Letter" and "House of the Seven Gables" were preceded by a variety of fancy sketches and historical narratives, published under the titles of "Twice-Told Tales" and "Mosses from an Old Manse," which in point of style and subtle analysis of character are among the most exquisite productions of American literature. The "Blithedale Romance," the next in the order of his novels, is marked by similar characteristics; and the "Marble Faun," the most elaborate of his works, contains pictures of Italian life and scenery of unsurpassed beauty. His posthumous novel "Septimius Felton" exhibits in strong degree the morbid and mystical tendencies of his earlier works. The "Tales of the Grotesque and Arabesque," and other fictions, by Edgar Allan Poe (1809–'49), exhibit extraordinary metaphysical acuteness and a wild and gloomy imagination; but his analytical power, unlike that of Hawthorne, is seldom pervaded by any moral sentiment, and his finest creations, though they are elaborated with skill, have little human interest. N. P. Willis (1806–'67) obtained a unique reputation as a delineator of the lights and shadows which flit over the surface of society, and his style, remarkable for its felicity, not to say happy audacity of expression, is in accord with his subjects. His prose writings, though including many tales, belong perhaps more properly to the departments of travels and belles-lettres. As pictures of domestic life among the ancients, the "Zenobia," "Probus," and "Julian" of William Ware (1797–1852) are not surpassed by any similar productions in English literature. To this class also belong "Philothea," a tale of Athens in the days of Pericles, by Mrs. Child, and "The Roman Traitor," by Henry William Herbert (1807–'58), well known under the pseudonyme of "Frank Forester." For invention and graphic power Herman Melville's tales of ocean adventure, including "Typee" and "Omoo," stand perhaps at the head of their class in American literature. The "Kaloolah" and "Berber" of W. S. Mayo are successful attempts in the same field. His later work, "Never Again," is in a different vein, and depicts society in the city of New York. One of the most popular novels of the present century was the "Uncle Tom's Cabin" of Mrs. Harriet Beecher Stowe, an anti-slavery fiction, which has circulated by millions of copies in many languages, and deeply moved the public heart in Europe and America, not more on account of the moral of the story than of its pathos, its humor, and its inimitable pictures of negro life. "Dred," her second anti-slavery romance, has perhaps more power than its predecessor, although it is less popular; and among her subsequent productions are the "Minister's Wooing," remarkable for its pictures of social and religious life in New England during the last century, the "Pearl of Orr's Island," "Agnes of Sorrento," "Old Town Folks," "My Wife and I," "Pink and White Tyranny," and "We and our Neighbors." The last three are satires on social and domestic evils. Of other novels founded upon the slavery question, "The White Slave," by Richard Hildreth, and "Ida May," by Mary Langdon (Mrs. Pike), may be cited as examples. Of prose fictions by authors who have won distinction principally in other walks of literature, the most deserving of notice are "Monaldi," by Washington Allston (1779–1843); "Paul Felton" and other tales published by R. H. Dana (born 1787) in the "Idle Man," a serial edited by himself; "Hyperion," a series of charming pictures of scenery and manners in Europe, connected by a thread of story, and "Kavanagh," by H. W. Longfellow (born 1807); "Leaves from Margaret Smith's Journal," by J. G. Whittier (born 1807); and "Elsie Venner" and "The Guardian Angel," by O. W. Holmes (born 1809). Among the younger writers of fiction, the most conspicuous are Bayard Taylor, whose "Hannah Thurston," "John Godfrey's Fortunes," "Story of Kennett," and "Joseph and his Friend" are careful and accurate pictures of American life and manners; Theodore Winthrop, whose death as a Union soldier in one of the earliest battles of the civil war gave to his "Cecil Dreeme," "John Brent," and other works, all posthumous, a sudden popularity, which, notwithstanding their merits, does not seem to be permanent; W. D. Howells (born 1837), whose "Suburban Sketches," "Their Wedding Journey," "A Chance Acquaintance," "A Foregone Conclusion," and "Private Theatricals" are distinguished by a charming style and a subtle and pleasant humor; and Julian Hawthorne, a son of Nathaniel (born 1846), who has attracted attention by novels of great promise, "Bressant," "Idolatry," and "Garth," which in style and tone exhibit many of his father's characteristic qualities. The humorous writers are represented by Seba Smith (1792–1868), author of the well known letters of "Major Jack Downing," Cornelius Mathews (born 1817), J. C. Neal (1807–'48), R. C. Sands (1799–1832), W. G. Clark (1810–'41), G. H. Derby (1824–'61), F. S. Cozzens (1818–'69), G. D. Prentice (1802–'70), and C. F. Briggs; besides Irving, whose "Knickerbocker's History of New York" is perhaps the most elaborate piece of humor in the national literature; Paulding, who in conjunction with Irving produced the "Salmagundi;" and some others mentioned above. Holmes has a copious vein of original humor, which appears to the best advantage in his poems and miscellaneous prose writings. The list of American humorous writings would be incomplete without an allusion to that class of grotesque tales of which the "Big Bear of Arkansas" and the "Quarter Race in Kentucky," by T. B. Thorpe, afford characteristic specimens. Among later humorists are Bret Harte, S. L. Clemens ("Mark Twain"), C. F. Browne ("Artemus Ward"), D. R. Locke ("Petroleum V. Nasby"), R. H. Newell ("Orpheus C. Kerr"), Charles G. Leland ("Hans Breitmann"), C. H. Webb ("John Paul"), and R. G. White (author of "The New Gospel of Peace"). Among other writers of prose fiction may be enumerated Sylvester Judd (1813–'53), author of "Margaret," a tragic tale of New England life, and "Richard Edney;" T. S. Fay, G. P. Thompson, T. S. Arthur, J. V. Huntington, J. T. Trowbridge, L. M. Sargent, F. W. Shelton, George Wood, J. H. Ingraham, P. P. Cooke, J. E. Cooke, J. G. Holland, R. B. Kimball, X. Donald McLeod, G. W. Curtis, A. S. Roe, E. P. Roe, H. P. Myers, J. B. Cobb, Robert T. S. Lowell, Edgar Fawcett, W. D. O'Connor, Henry James, jr., W. H. Peck, Theodore Tilton, Charles Dimitry, E. E. Hale, James De Mille, J. W. De Forest, T. W. Higginson, Frank Lee Benedict, and T. B. Aldrich. The female writers of fiction of this period constitute a numerous and important body, and the works of some of them are not exceeded in popularity by any contemporary writings of their class. It will suffice to mention, in addition to works already referred to, the several series of "Pencil Sketches," by Miss Eliza Leslie (1787–1858); the "Three Experiments of Living," by Mrs. H. F. Lee; "The Wide, Wide World" and "Queechy," by Miss Susan Warner; "Fern Leaves," "Ruth Hall," and other popular productions, by Mrs. S. P. W. Parton ("Fanny Fern"); "The Household of Bouverie," by Mrs. C. A. Warfield; "Naomi," by Mrs. E. B. Lee; "Charms and Counter-Charms," by Miss M. J. McIntosh; besides numerous volumes by Mrs. Hale, Mrs. E. C. Embury, Mrs. C. L. Hentz, Mrs. A. S. Stephens, Mrs. E. Oakes Smith, Mrs. Ellet, Mrs. A. C. (Mowatt) Ritchie, Mrs. E. D. E. N. Southworth, Miss A. B. Warner, Mrs. E. S. Phelps (Trusta), Mrs. A. B. (Neal) Haven, Miss Alice Cary, Miss Caroline Chesebro', Mrs. E. Robinson ("Talvi"), Miss Maria S. Cummins, Mrs. Harriet (Prescott) Spofford, Mrs. Virginia Terhune ("Marion Harland"), Mrs. A. J. (Evans) Wilson, Mrs. Martha T. Lamb, Mrs. M. J. Holmes, Mrs. M. H. Eastman, Mrs. Elizabeth Stoddard, Mrs. M. A. Sadlier, Mrs. M. A. Denison, Mrs. M. C. Lawrence, Miss Amanda M. Douglas, Miss Frances C. Fisher, Miss Louisa M. Alcott, Miss Anna E. Dickinson, Mrs. A. M. Seemuller, Mrs. Mary Healy Bigot, Mrs. Jane G. Austin, Mrs. R. H. Davis, and many others.—In intimate connection with the departments already treated is that of juvenile literature, to which several authors have exclusively devoted themselves, and among the contributors to which are many of those previously mentioned. S. G. Goodrich's numerous little books for children, published under the pseudonyme of "Peter Parley," have had a prodigious circulation in Europe as well as America. Nathaniel Hawthorne wrote some delightful tales for children; Jacob Abbott (born 1803) is the author of the popular "Rollo," "Lucy," "Franconia," and other series of stories, and of numerous juvenile histories; and W. M. Simonds, John Bonner, F. C. Woodworth, George Taylor, Charles Nordhoff, William T. Adams ("Oliver Optic"), Elijah Kellogg, Frank R. Stockton, Horatio Alger, jr., Mrs. E. C. Judson ("Fanny Forester," 1817–'54), Mrs. Lippincott ("Grace Greenwood"), Mrs. Sigourney, Miss C. M. Sedgwick, Miss McIntosh, Mrs. L. C. Tuthill, Mrs. Parton, Mrs. L. M. Child, Mrs. A. B. (Neal) Haven, Miss L. M. Alcott, Mrs. H. C. Knight, Mrs. A. A. Carter, Mrs. E. S. Phelps and her daughter Miss E. S. Phelps, Mrs. Hubbell, Mrs. Helen Kendrick Johnson, Mrs. L. C. Moulton, Mrs. A. M. Diaz, Mrs. Mary Mapes Dodge, Mrs. Fanny Barrow, Miss Sarah C. Woolsey ("Susan Coolidge"), and many others have devoted a large portion of their time to this species of literature.—The poetry of this period has shown a remarkably healthy and abundant development; and it is probable that the number of writers is more numerous here than in any other country. Notwithstanding also the limited range of native subjects, which makes the imaginative literature of the country in some respects an imitation or rather a continuation of that of other lands, the characteristic features of national scenery, legend, and history have not failed of illustrators, while the familiar imagery of an older civilization has been often reproduced with force and originality. Among those who have made a felicitous use of native materials, one of the most eminent and thoroughly American is William Cullen Bryant (born 1794), whose poems, the fruits of meditation rather than of passion or imagination, are remarkable for their descriptive powers, their serene and elevated philosophy, and noble simplicity of language. Richard H. Dana was one of the first in America to break away from the school of Pope, and his "Buccaneer," a narrative of crime and retribution, had no slight influence in directing the poetical taste of the country. Charles Sprague (1791–1875) wrote an "Ode to Shakespeare," a metrical essay on "Curiosity," and a few other pieces. J. G. Percival (1795–1856) possessed a remarkable command of language and metre, and his "Coral Grove" and "New England" are established favorites. The few poetical remains of Washington Allston (1779–1843), including the "Sylphs of the Seasons," evince an exuberant fancy and much metrical skill. Joseph Rodman Drake (1795–1820) produced "The Culprit Fay," an imaginative poem, exquisitely versified. Fitz-Greene Halleck (1790–1867) wrote little, but during his life was one of the most popular of American poets, and his "Marco Bozzaris" is still universally known among his countrymen. The Scripture pieces of N. P. Willis are written with feeling and artistic finish; in his other poems the verbal felicity and sprightly fancy characteristic of his prose writings are discernible. The few brief poems of Ralph Waldo Emerson (born 1803), of which "The Problem" and the lines "To a Humble Bee" afford examples, are remarkable for their quaintness and originality. The early song writers of the period are represented by G. P. Morris (1802–'64), the most popular of his class in America, Edward Coate Pinkney (1802–'28), and C. F. Hoffman, whose amatory or convivial verses are gracefully written and well adapted to music. Among other early writers of the period who are remembered for one or more successful poems are F. S. Key (1779–1843), author of the "Star-Spangled Banner;" Samuel Woodworth (1785–1842), of "The Old Oaken Bucket;" R. H. Wilde (1789–1847), of the song "My Life is like the Summer Rose;" and John Howard Payne (1792–1852), whose "Home, Sweet Home" is known wherever the English language is spoken. Among later song writers is Stephen C. Foster (1826–'64), the most popularly successful and the most peculiarly American of all. The poems of E. A. Poe form a fitting accompaniment to his prose writings, and are characterized by a shadowy and gloomy imagination, and a fascinating melody of rhythm. "The Raven" illustrates his facility in harmonizing sentiment with rhythmical expression; and his "Annabel Lee," "Haunted Palace," and "Bells" are constructed with equal skill. The most artistic and cosmopolitan of American poets, and the most widely read abroad, is H. W. Longfellow, whose genius has been powerfully influenced by the literature and historic associations of the old world, while in the choice and treatment of his principal subjects he is eminently American. Much of the poetry of J. G. Whittier was prompted by his opposition to slavery, and in occasional pieces he rises to a strain of genuine lyrical exaltation. Of this character are his "Massachusetts to Virginia" and "Astræa at the Capitol." In other poems he unites tenderness and grace with much simplicity of language. All of his descriptive poems, but especially "Snow-Bound," his masterpiece, are strikingly national. James Russell Lowell (born 1819) is one of the most versatile poets of this period, and has won high reputation as a prose writer by several volumes of essays, chiefly on literary topics. His serious poems are earnest and philanthropic in tone, elevated in sentiment, and of high artistic merit. He is perhaps the ablest of American satirists, and has gained a unique reputation as a humorist by his "Biglow Papers," in which the peculiar phraseology of New England is given with great verbal and idiomatic correctness. The prose introductions to these poems have a subtle humor which can be best appreciated by those familiar with the local peculiarities they illustrate. Not less conspicuous as a humorist is O. W. Holmes, the most effective writer of the school of Pope, and distinguished by a clear, concise, and manly style. For the mingled pungency and geniality of his humor he is unrivalled among American poets. In his knowledge of local dialects and idioms he is not inferior to Lowell. J. G. Saxe (born 1816) is known chiefly as a humorous poet, and his verses enjoy considerable popularity. A. B. Street (born 1811) has devoted himself more than any other native poet to the romantic aspects of American scenery and forest life, and his works contain many striking and picturesque descriptive passages. Among other poets and occasional writers of verses of this period, all of whom have produced some pieces of high merit, are John Pierpont (1785–1866), John Neal, J. G. Brainard, Andrews Norton (1786–1853), Henry Ware, jr. (1794–1843), W. G. Simms, R. C. Sands, G. W. Doane, A. G. Greene, Rufus Dawes, Sumner Lincoln Fairfield, James Aldrich, George Lunt, G. W. Bethune, G. D. Prentice, Grenville Mellen, William Croswell, Thomas Ward, W. D. Gallagher, Park Benjamin, Albert Pike, Jones Very, Ralph Hoyt, W. G. Clark, Seba Smith, W. E. Channing, H. T. Tuckerman, H. B. Hirst, W. H. C. Hosmer, Epes Sargent, T. W. Parsons, A. C. Coxe, G. H. Colton, W. W. Story, W. R. Wallace, T. D. English, C. G. Eastman, P. P. Cooke, C. P. Cranch, W. H. Burleigh, Isaac McLellan, and J. T. Fields; and among the younger writers, J. R. Thompson, G. H. Boker, T. B. Read, Bayard Taylor, R. H. Stoddard, W. Allen Butler, P. H. Hayne, C. G. Leland, R. T. S. Lowell, T. B. Aldrich, A. J. H. Duganne, E. C. Stedman, W. B. Wright, B. F. Taylor, H. H. Brownell, Forceythe Willson, R. W. Wright, J. T. Trowbridge, William Winter, Joaquin Miller, John Hay, Bret Harte, Henry Timrod, George Arnold, R. W. Gilder, G. P. Lathrop, and Walt Whitman, whose unrhymed and rhapsodical poems, severely criticised at home, have found their warmest admirers in England. The female poets of the period comprise Mrs. L. H. Sigourney (1791–1865), author of many beautiful pieces characterized by feminine delicacy and religious sentiment; Mrs. Maria Brooks ("Maria del' Occidente," 1795–1845), whose principal poem, "Zophiel," evinces a high degree of imaginative power; Lucretia Maria Davidson (1808–'25), and her sister Margaret Miller Davidson (1823–'38), who are instances of rare though melancholy precocity; Mrs. Frances Sargent Osgood (1811–'50), remarkable for her playfulness of fancy and facility of expression; Mrs. Julia Ward Howe (born 1819), whose "Passion Flowers" and other poems are distinguished by a peculiar earnestness of feeling and expression; Mrs. Frances Anne Kemble (born 1811), who exhibits similar characteristics; Mrs. E. Oakes Smith, author of a melodious and imaginative poem entitled "The Sinless Child;" Mrs. Margaret J. Preston, whose chief poem, "Beechenbrook," was very popular in the south during the civil war; Mrs. Caroline Gilman, Mrs. S. J. Lippincott, Mrs. A. B. Welby, Miss H. F. Gould, Mrs. E. C. Embury, Mrs. Sarah Helen Whitman, Mrs. A. C. (Lynch) Botta, Mrs. Estelle Anna Lewis, Mrs. Haven, Miss Alice Cary and her sister Phœbe Cary, Mrs. E. F. Ellet, Mrs. S. J. Hale, Miss Caroline May, Mrs. Maria Lowell, Miss Edna Dean Proctor, Mrs. Rosa Vertner (Jeffrey), Mrs. L. V. French, Mrs. M. S. B. Dana (Shindler), Mrs. S. M. B. Piatt, Mrs. E. C. Kinney, Miss Emma Lazarus, Mrs. Celia Thaxter, Miss Lucy Larcom, Mrs. Rose Terry Cooke, Mrs. Elizabeth (Akers) Allen, Miss Laura C. Redden ("Howard Glyndon"), Mrs. Helen Hunt (Jackson), and many others. Dramatic literature has been cultivated by comparatively few writers, and, with occasional exceptions, nothing of very decided mark, either in style, sentiment, or plot, has yet been accomplished. J. A. Hillhouse (1789–1841) excelled in that species of poetic literature illustrated by the writings of Browning, Henry Taylor, and others in England, which may be called the written drama. His "Hadad," founded upon Jewish tradition, "Percy's Masque," and other dramas, though unfitted for representation, are conceived with taste and carefully finished. G. H. Boker has produced "Calaynos," a tragedy founded on an incident in the history of the Spanish Moors, and other dramatic pieces of more than ordinary merit; and Mrs. J. W. Howe, a high-wrought drama entitled "The World's Own." Among other works of this class may be mentioned "Brutus," by J. H. Payne; "Metamora," by J. A. Stone; "Jack Cade," by R. J. Conrad; "Tortesa the Usurer" and "Bianca Visconti," by N. P. Willis; "Velasco," by Epes Sargent; "The Gladiator," by R. M. Bird; "Witchcraft," by Cornelius Mathews; "Fashion," by Mrs. A. C. (Mowatt) Ritchie; "The Prophet," by Bayard Taylor; and "The Spanish Student," "Christus," and "Masque of Pandora," by H. W. Longfellow. Several of these have proved good acting plays, and still retain possession of the stage. Several writers have executed metrical translations of merit from the German, Italian, and other languages. The most eminent of these are Longfellow, whose translation of Dante is the best in the English language, and whose versions of Bishop Tegnér's "Children of the Lord's Supper" and *Der schwarze Ritter* and other ballads by Uhland are well known; Bryant, who has made an excellent version of Homer; and Bayard Taylor, who has made a masterly rendering of Goethe's *Faust* in the original metres. C. P. Cranch has made a good translation of Virgil's Æneid. C. T. Brooks has translated *Faust*, Schiller's *Wilhelm Tell*, Richter's *Titan* and *Hesperus*, and numerous other pieces from the German; C. G. Leland, the choicest songs of Heine; W. H. Furness, Schiller's "Song of the Bell;" and N. L. Frothingham and J. S. Dwight, many of the minor poems of this and other German authors. T. W. Parsons has made one of the best English translations of Dante's *Inferno;* George Ticknor has versified choice extracts from the Spanish poets; and R. H. Wilde, Dr. Mitchell, and Mrs. Nichols have translated with taste from Tasso, Sannazaro, and Manzoni.—Under the head of criticism, essays, belles-lettres, lectures or discourses, and that species of miscellaneous works which owe their charm to a felicitous blending of fact and fancy, or of sentiment and thought, may be classed a numerous body of authors who were so inadequately represented in the two preceding periods that the department now under consideration may almost be said to have sprung into existence since 1820. The establishment of the "North American Review" in 1815, followed by that of the "American Quarterly Review," the "Southern Quarterly Review," the "Christian Examiner," the "Knickerbocker Magazine," the "Dial," "Harper's Monthly," "Putnam's Monthly," the "Atlantic Monthly," and other periodicals, gave the first considerable impulse to literary criticism and essay writing on a comprehensive and philosophic scale; and the production of the essays of William Ellery Channing (1780–1842) on "National Literature," "Milton," "Napoleon Bonaparte," "Fénelon," and "Self-Culture," and of the thoughtful and highly finished articles by R. H. Dana, published in his own "Idle Man" and the "North American Review," may be said to have formed an era in the literary history of the country. Contemporary with these were John Quincy Adams, William Tudor, Joseph Story, Edward and A. H. Everett, W. H. Prescott, F. C. Gray, George Ticknor, E. T. Channing, Robert Walsh, G. C. Verplanck, J. G. Palfrey, Jared Sparks, Samuel Gilman, William Ware, R. C. Sands, Orville Dewey, Dr. J. W. Francis, W. G. Simms, John Neal, Francis Wayland, Henry Reed, F. L. Hawks, C. S. Henry, J. T. Buckingham, and

H. S. Legaré, most of whom have written with taste upon subjects connected with philosophy, morals, political and social economy, and general literature. Prominent among the later essayists is R. W. Emerson, an original and independent thinker, whose views of religion and in some degree of society may be described as the opposite of all those founded upon tradition and authority. He has written in an abstract manner upon social, moral, and political questions; and his style, though sometimes obscure by reason of his attempts to condense a philosophic theory into a few brief terms, has a finished beauty and significance which have secured him a wide circle of admirers, particularly in New England. His published works comprise several series of "Essays," "The Method of Nature," "Representative Men," "English Traits," "The Conduct of Life," "Society and Solitude," and "Letters and Social Aims," several of which have been expanded from lectures and addresses, a department of literature to which he has principally devoted himself. Of the school of Emerson was Margaret Fuller Ossoli (1810–'50), author of "Woman in the Nineteenth Century," an earnest protest against the commonly received views of the social position of women, and "Papers on Literature and Art," some of which originally appeared in the "Dial," a quarterly publication which was for several years the organ of Emerson and his friends. In general acquirements and conversational powers she was probably the most noted woman of her time in America. The most conspicuous names of other writers in this department are those of E. P. Whipple, author of many papers, chiefly on literature, written in a lively and perspicuous style; H. T. Tuckerman, whose contributions to critical literature show a refined taste and a liberal cultivation of mind and heart; O. A. Brownson, a bold and powerful writer on religion, metaphysics, and politics; J. R. Lowell, whose essays "Among my Books" show wide reading in several languages, and much subtle thought; John Fiske, whose "Outlines of Cosmic Philosophy" is a lucid exposition of the doctrine of evolution; G. S. Hillard, C. C. Felton, F. H. Hedge, G. E. Ellis, W. H. Furness, W. B. O. and O. W. B. Peabody, G. H. Calvert, Henry Giles, Mrs. Mary Lowell Putnam, R. W. Griswold, J. F. Clarke, A. P. Peabody, C. H. Brigham, O. B. Frothingham, Thomas Hill, E. C. Stedman, and W. C. Wilkinson. Anything like a complete enumeration of the writers who have gained distinction in the wide field of belles-lettres or magazine literature would be impossible within the limits of this article; and only those who are generally known or who may stand as representatives of their class can be mentioned. The most distinguished of all is Washington Irving, whose "Crayon Papers," published in England in 1822 under the title of "The Sketch Book," represents perhaps the author's most successful attempts in elegant literature. The "Inklings of Adventure," "Pencillings by the Way," "Letters from under a Bridge," and other piquant sketches of people and manners, by N. P. Willis; the series of discursive essays by O. W. Holmes, entitled "The Autocrat of the Breakfast Table," "The Professor at the Breakfast Table," and "The Poet at the Breakfast Table;" the "Reveries of a Bachelor," by D. G. Mitchell (Ik Marvel); the "Potiphar Papers," by G. W. Curtis; "Meister Karl's Sketch Book," by C. G. Leland; and the "Fern Leaves" of Mrs. Parton, are popular examples of what has been accomplished by other authors. To these names may be added those of John Sanderson, G. W. Bethune, M. M. Noah, N. Biddle, Mrs. C. Gilman, T. S. Fay, R. M. Charlton, J. J. Jarves, A. K. Gardner, A. B. Alcott, C. F. Hoffman, E. S. Gould, E. Sanford, G. H. Calvert, L. L. Noble, Park Benjamin, W. G. and L. G. Clark, E. A. Poe, Mrs. Kirkland, Theodore Sedgwick, H. W. Herbert, H. B. Wallace, C. W. Webber, G. W. Peck, W. E. Burton, Robert Turnbull, J. L. Motley, Miss Susan Fenimore Cooper, Mrs. Botta, Epes Sargent, H. D. Thoreau (whose writings, showing much acute and original observation of nature as well as great eccentricity of character in the author, have become remarkably popular since his death), Thomas Starr King, W. R. Alger, E. H. Chapin, Samuel Osgood, H. W. Bellows, Parke Godwin, C. A. Bristed ("Carl Benson"), J. G. Holland ("Timothy Titcomb"), R. G. White, J. Milton Mackie, T. W. Higginson, D. H. Strother, C. F. Briggs, E. E. Hale, G. D. Prentice, George Sumner, Miss Mary Abigail Dodge ("Gail Hamilton"), John Burroughs, Fitzhugh Ludlow, Charles T. Congdon, C. E. Norton, and Theodore Winthrop. Among the works illustrating English literature are the lectures on Shakespeare by R. H. Dana and H. N. Hudson, and the editions of the poet by G. C. Verplanck, H. N. Hudson, R. G. White, and, latest of all, the great variorum edition by Horace Howard Furness, the publication of which began in 1871; the edition of Spenser by G. S. Hillard; editions of Wordsworth and Gray by Henry Reed, of Milton by C. D. Cleveland, and of Coleridge by W. G. T. Shedd; the elaborate series of British poets by F. J. Child, assisted by J. R. Lowell and others; and various writings by R. H. Dana, A. H. Everett, J. R. Lowell, J. S. Hart, E. P. Whipple, and R. W. Emerson. Translations from the German metaphysicians, historians, and theologians have been made by George Bancroft, S. M. Fuller, G. H. Calvert, W. H. Channing, F. H. Hedge, Samuel Osgood, W. T. Harris, and George S. Morris, and by Philip Schaff and others in the American edition of Lange's commentary; and from educational and scientific authors as well as writers of fiction in Germany and France, by a variety of hands. Among the most successful of the translators from the French are Miss Mary L. Booth and Mrs. M. H. Robinson. The department of oratory and political science, though relatively less prominent than in the preceding period, occupies an important place in contemporaneous American literature; and the speeches and writings of Daniel Webster (1782–1852), Henry Clay (1777–1852), and J. C. Calhoun (1782–1850), considered merely as literary productions, are among the intellectual triumphs of the country. For dignity of expression, breadth and force of thought, and a style strong, simple, and sometimes grand, the forensic arguments and public and political speeches of Webster may rank with the masterpieces of oratory in any language. The spontaneous, impassioned eloquence of Clay, on the other hand, depended so much for its effect upon the voice and manner of the speaker, that his reputation will be mostly traditional. His published speeches give little indication of the mastery of the feelings for which he was almost unrivalled. Calhoun's eloquence was plain, strong, concise, and only occasionally impassioned; and his power, as Webster has observed, "consisted in the plainness of his propositions, the closeness of his logic, and in the earnestness and energy of his manner." To the political orators and statesmen of this period belong also John Quincy Adams (1769-1848), remarkable for the universality of his knowledge and his independence of judgment; John Randolph of Roanoke (1773–1833), an eccentric but powerful and pointed speaker, and a master of invective; Albert Gallatin (1761–1849); R. Y. Hayne (1791–1840), the eloquent antagonist of Webster; De Witt Clinton (1769–1828), Tristam Burges (1770–1853), George McDuffie (1788–1851), Silas Wright (1795–1847), H. S. Legaré (1797–1843), W. C. Preston (1794–1860), S. S. Prentiss (1808–'50), T. H. Benton (1782–1858, whose "Thirty Years' View" and "Abridgment of the Debates in Congress" afford invaluable materials to the historian of national politics), A. H. Everett (1792–1847), J. R. Poinsett (1779–1851), Lewis Cass (1782–1866), Levi Woodbury (1789–1851), Caleb Cushing (born 1800), John Sergeant (1779–1852), J. J. Crittenden (1787–1863), W. H. Seward (1801–'72), J. H. Hammond (1807–'64), R. C. Winthrop (1809), H. A. Wise (1806), S. A. Douglas (1813–'61), and R. M. T. Hunter (1809). The most accomplished orator of the period with respect to rhetorical finish and elocution was Edward Everett (1794–1865), whose productions, including his oration on Washington, which was delivered before public assemblies in many parts of the country, are thoroughly American in tone, and possess a permanent and intrinsic worth. Rufus Choate (1799–1859), in his forensic arguments and occasional public addresses, exhibited not less rhetorical excellence and more fervor than Everett; and Charles Sumner (1811–'74) excelled in strength and clearness of statement, ripe scholarship, and nobility of diction. Among the anti-slavery orators, to which class Mr. Sumner properly belonged, were William Lloyd Garrison (born 1804), whose popular addresses were singularly effective; Wendell Phillips (1811), a vigorous and impulsive speaker, frequently rising to a strain of impassioned eloquence; J. R. Giddings (1795–1864), Theodore D. Weld (1803), Theodore Parker (1810–'60), Henry Ward Beecher (1813), R. W. Emerson, Frederick Douglass (1817), Anson Burlingame (1820–'70), and G. B. Cheever (1807), whose oratory in general exhibits similar characteristics. The list of occasional orators, in addition to the names of most of the foregoing, includes those of Joseph Story (1779–1845), James Kent (1763–1847), G. C. Verplanck (1786–1870), Horace Binney (1780–1875), T. S. Grimke (1786–1834), Orville Dewey (1794), Horace Bushnell (1802–'76), E. H. Chapin (1814), H. B. Bascom (1796–1850), G. S. Hillard (1808), H. W. Bellows (1814), R. H. Dana, jr. (1815), and many others. The political writers comprise William Sullivan (1774–1839), Mathew Carey (1760–1839), J. T. Buckingham, Martin Van Buren (1782–1862), W. L. Marcy (1786–1857), Thomas Ritchie, Joseph Gales, Robert Walsh, William Leggett (1802–'39), Amos Kendall (1789–1869), Calvin Colton, J. H. Hammond, Nathan Hale, David Hale, Richard Hildreth, Joshua Leavitt, Morton McMichael, Hamilton Pleasants, T. R. R. Cobb, G. D. Prentice, W. C. Bryant, J. G. Palfrey, Robert Barnwell Rhett, Joseph Chandler, James Gordon Bennett, J. D. B. De Bow, John Fletcher, George Fitzhugh, J. L. O'Sullivan, Edwin Croswell, Thurlow Weed, Horace Greeley, J. W. Forney, W. L. Garrison, N. P. Rogers, C. C. Hazewell, John Bigelow, Parke Godwin, H. J. Raymond, E. L. Godkin, N. Paschall, B. Gratz Brown, C. H. Ray, James Brooks, Erastus Brooks, Charles Nordhoff, Charles T. Congdon, and many others. Under this head also come the comprehensive "Commentaries on the Constitution of the United States," by Justice Story, the lectures on the same subject by W. A. Duer (1780–1858), and the "Constitutional History of the United States," by G. T. Curtis. The most eminent writers on political economy are H. C. Carey (born 1793), whose "Principles of Political Economy," "Credit System in France, England, and the United States," "The Past, the Present, and the Future," and numerous other works, maintain protection doctrines in a clear, terse style; President Francis Wayland (1796–1865) and Henry Vethake, both advocates of free trade, who have published valuable text books on the subject; Francis Lieber, A. H. Everett, William Leggett, Beverley Tucker, Albert Gallatin, John Bristed, Calvin Colton, Condy Raguet, Stephen Colwell, Francis Bowen, Alonzo Potter, E. C. Seaman, E. Peshine Smith, George Opdyke, W. M. Gouge, William Maclure, Edward Atkinson, and W. G. Sumner. The writers on social science and ethics comprise Francis Lieber, author of treatises on "Liberty and Self-Government" and "Political Ethics;" G. H. Calvert, T. Sedgwick, Adam Gurowski, Bishop J. H. Hopkins, and E. Mulford, who have discussed the subject generally. W. L. Garrison, Richard Hildreth, T. D. Weld, William Goodell, Lydia M. Child, H. R. Helper, M. D. Conway, E. M. Stearns, T. Stringfellow, G. Fitzhugh, A. T. Bledsoe, J. H. Hammond, Nehemiah Adams, J. H. Hopkins, Henry Wilson, and others have written on the institution of slavery; W. P. Foulke, L. Dwight, J. S. Gould, and Miss Dorothea L. Dix, on prison discipline and kindred topics; and Charles Francis Adams, jr., and his brother Henry Brooks Adams, on the management of railroads.—In no department has the intellectual development of the country been more conspicuous than in that of jurisprudence, and the treatises, digests, and reports emanating from American authors and jurists already fill several thousand volumes, and form a valuable addition to legal literature. The "Commentaries on American Law," by James Kent, published in 1826–'30, are written with great clearness and force of reasoning, and constitute the chief manual of general reference and elementary instruction. Of the numerous works of Justice Story, those on equity jurisprudence, partnership, bailments, and "The Conflict of Laws," are well known everywhere; the "Elements of International Law" and "History of the Law of Nations," by Henry Wheaton, have become standard works of reference throughout the world; and the treatises of Edward Livingston on penal law, of Simon Greenleaf on evidence, of Willard Phillips on insurance, of F. Wharton on criminal law and other subjects, besides many by David Hoffman, St. George Tucker, J. K. Angell, John Bouvier, G. T. Curtis, L. S. Cushing, W. A. and John Duer, F. Hilliard, Murray Hoffman, Theophilus Parsons, Theodore Sedgwick, W. W. Story, I. F. Redfield, J. P. Bishop, T. M. Cooley, B. V. and Austin Abbott, A. M. Burrill, Charles Edwards, Isaac Edwards, Alfred Conkling, W. B. Lawrence, J. N. Taylor, John Townshend, R. H. Tyler, Emory Washburn, R. H. Dana, jr., Theodore D. Woolsey, and others, are creditable to the legal learning of the country.—The theological and religious writers of the period comprise a numerous and able body, whose works have in many instances become standard authorities on the subjects of which they treat, and, in view of the multiplicity of sects from which they emanate, express unusually broad and catholic views. In the department of Biblical criticism American theologians are everywhere honorably distinguished. Of Presbyterian writers, the most eminent are Samuel Davies (1724–'61); Samuel Miller (1769–1850), author, among other works, of several treatises on the distinguishing features of Presbyterianism; Edward Robinson (1794–1863), best known by his researches in Biblical geography; Albert Barnes (1798–1870), whose "Notes on the Gospels" and commentaries on other portions of Scripture are widely known in America and England; Nicholas Murray ("Kirwan," 1803–'61), author of several controversial publications; Ashbel Green (1762–1848), Gardiner Spring (1785–1873), Charles Hodge (born 1797), James Richards (1793–1843), R. J. Breckenridge (1800–'71), Archibald, J. W., and Joseph A. Alexander, T. H. Skinner, I. S. Spencer, William Adams, Thomas Smyth, Robert Baird, J. H. Thornwell (1811–'62), and Henry B. Smith. The Trinitarian Congregationalists are represented by Moses Stuart (1780–1852), author of various Scriptural commentaries, and distinguished as a philologist; Leonard Woods (1798–1854), Horace Bushnell, Edwards A. Park, Lyman Beecher (1775–1863), Edward Beecher, Henry Ward Beecher, N. W. Taylor, Bennet Tyler, E. N. Kirk, Nehemiah Adams, Mark Hopkins, Nathan Lord, Joel Hawes, Leonard Bacon, G. B. Cheever, J. P. Thompson, T. C. Upham, J. Torrey, W. G. T. Shedd, H. M. Dexter, and George Punchard, author of a "History of Congregationalism," &c. About the commencement of this period a memorable controversy took place in New England between Samuel Worcester, representing the conservative or orthodox Congregationalists, and W. E. Channing in behalf of the Unitarians, who thenceforth became an independent and, in proportion to their numbers, an important sect. The writings of Channing had great influence in moulding the opinions now generally held by Unitarians in the United States and Great Britain; and contemporary with him was a body of divines and scholars of considerable literary culture, resident chiefly in Boston and its vicinity, whose education was acquired at Harvard college, where a large proportion of the Unitarian clergy have since graduated. Prominent among these were Andrews Norton (1786–1853), author of a treatise on the "Genuineness of the Gospels;" Henry Ware, jr., and William Ware, J. G. Palfrey, Jared Sparks, N. L. Frothingham, James Walker, Orville Dewey, F. W. P. Greenwood, W. H. Furness, and G. W. Burnap. Of somewhat later date are A. P. Peabody, F. H. Hedge, G. E. Ellis, H. W. Bellows, A. A. Livermore, E. H. Sears, A. B. Muzzey, J. F. Clarke, and Samuel Osgood, afterward an Episcopalian. Distinguished from these is a rationalistic school of Unitarianism, chiefly represented by Theodore Parker (1810–'60), whose writings evince extensive scholarship and furnish frequent examples of rhetorical beauty and force. O. B. Frothingham, C. A. Bartol, John Weiss, and M. D. Conway are the most conspicuous of his successors of the same school. The principal writers of the Protestant Episcopal denomination are Bishop C. P. McIlvaine, author of a treatise on the "Evidences of Christianity;" Bishop T. C. Brownell, author of commentaries on the "Book of Common Prayer;" Bishops Alonzo Potter, George Burgess, J. M. Wainwright, J. H. Hopkins, A. C. Coxe, and W. I. Kip; S. F. Jarvis, S. H. Tyng, F. L. Hawks, J. S. Stone, F. D. Huntingdon, S. H. Turner, G. T. Bedell, R. A. Hallam, T. W. Coit, Calvin Colton, A. H. Vinton, J. A. Spencer, and

Samuel Seabury. Among the Baptists, the most noted are President Francis Wayland, William Hague, H. B. Hackett, H. J. Ripley, Pharcellus Church, Baron Stow, Alvah Hovey, W. R. Williams, T. J. Conant, J. Belcher, R. Turnbull, Richard Fuller, and J. B. Jeter; and among the Methodists, Nathan Bangs, P. D. Gorrie, John and Robert Emory, Stephen Olin, H. B. Bascom, D. D. Whedon, J. McClintock, James Strong, George Peck, Abel Stevens, W. P. Strickland, D. Curry, James Floy, D. Wise, Osmyn Baker, T. H. Stockton, E. O. Haven, C. F. Deems, H. N. McTyeire, T. O. Summers, and Alexander Green. The Roman Catholics are represented by Archbishops F. P. and P. R. Kenrick and John Hughes, the last two chiefly distinguished as controversial writers, Bishops J. England and H. Spaulding, I. T. Hecker, and O. A. Brownson, who has written several of his most noticeable review articles on theological subjects. Among the Swedenborgians, the prominent names are George Bush, author of a treatise on the "Doctrine of the Resurrection of the Body" and numerous commentaries and miscellaneous writings; Henry James, author of "The Secret of Swedenborg" and other works; Theophilus Parsons, author of "Deus Homo," "The Finite and the Infinite," and several volumes of essays; Chauncey Giles, author of several works on the future life; B. F. Barrett, Sampson Reed, and Richard De Charms. Philip Schaff, J. W. Nevin, and H. Harbaugh are the chief writers of the German Reformed, S. S. Schmucker and C. P. Krauth, of the Lutheran church; Hosea Ballou, E. H. Chapin, T. Whittemore, and T. B. Thayer, of the Universalist denomination; and T. Evans and S. M. Janney, of the society of Friends. Many of the above, including Brownson, Parker, Walker, and Wayland, have written on moral philosophy and metaphysics. The school of Locke is represented by Francis Bowen, Frederick Beasley, and others; while Parker, Walker, James Marsh, and Emerson have borrowed more or less from the German idealists and the French eclectics. C. S. Henry and O. W. Wight have made the philosophy of Cousin familiar to American readers; J. Marsh has expounded the doctrines of Coleridge; and Samuel Tyler has produced, in his "Discourse on the Baconian Philosophy," one of the most profound metaphysical disquisitions of the century. Other contributors to this department are Herman Hooker, Hubbard Winslow, Joseph Haven, H. P. Tappan, Asa Mahan, T. C. Upham, Rowland Hazard, Henry James, W. G. T. Shedd, B. F. Cocker, J. Bascom, W. D. Wilson, L. P. Hickok (whose writings on the higher branches of philosophy are among the ablest specimens of profound discussion), Noah Porter, J. McCosh, and Mark Hopkins.—Under the head of philology may be mentioned the two great English dictionaries by Noah Webster (1758–1843) and Joseph E. Worcester (1784–1865), which have superseded all others in popular use in the United States; the "Lectures on the English Language" and other works by G. P. Marsh; the "Dictionary of Americanisms," by J. R. Bartlett; and the writings of Goold Brown, W. C. Fowler, and others who have devoted themselves particularly to the structure and etymology of the English language. The aboriginal languages of North America have been treated by John Pickering, Albert Gallatin, H. R. Schoolcraft, P. E. Duponceau, E. G. Squier, W. W. Turner, Mrs. M. H. Eastman, and J. Hammond Trumbull; and grammars and vocabularies of the most important dialects have been prepared by missionaries and others specially interested in the subject. In oriental literature the investigations of American philologists have been of great value; and to American scholars, and particularly missionaries, Europe is largely indebted for its knowledge of a number of the languages of eastern Asia, Africa, and the Pacific islands. Among those who have gained eminence by their contributions to Biblical philology are Edward Robinson and Tayler Lewis, both also distinguished as Greek scholars, Moses Stuart, S. H. Turner, J. W. Gibbs, B. B. Edwards, G. R. Noyes, George Bush, T. J. Conant, and H. B. Hackett. In other branches of oriental philology the chief works are the "Burmese Dictionary," by Adoniram Judson; the English and Chinese vocabularies of S. Wells Williams; the "Notes on Chinese Literature," by A. Wiley; the Japanese dictionary of J. C. Hepburn; the Karen grammar and dictionary by F. Mason; the Hebrew grammar by W. H. Green; and the "Lectures on Language" and other works of W. D. Whitney, who is distinguished for varied and profound learning; besides the writings of W. W. Turner, E. E. Salisbury, J. G. Palfrey, E. Riggs, W. W. Greenough, and Charles Kraitsir, several of whom have contributed important papers to the "Journal of the American Oriental Society." Francis A. March, in his "Anglo-Saxon Grammar" and other works, has given important aid to the philological study of English. Among miscellaneous philological writers are C. A. Goodrich, Prof. Schele de Vere, and Horatio Hale, author of the "Ethnography and Philology of the United States Exploring Expedition" under the command of Capt. Wilkes.—The contributions to ethnology comprise some of the most costly works which have yet appeared from the American press. Among these may be enumerated the "Crania Americana," "Crania Ægyptiaca," and other works by S. G. Morton (1799–1851); the "Biblical and Physical History of Man," by J. C. Nott (1804–'73); the elaborate "Types of Mankind" and "Indigenous Races of the Earth," both profusely illustrated, by J. C. Nott and G. R. Gliddon; the "Diversity of Origin of Human Races," by Louis Agassiz (1807–'74); the "Doctrine of the Origin of the Human Race," by John Bachman; the "Progress of Ethnology," by

J. R. Bartlett; the "Races of Men and their Geographical Distribution," by Charles Pickering; "Races of the Old World," by C. L. Brace; and other works by Arnold Guyot, F. W. Redfield, T. Smyth, and A. Meigs. Intimately connected with this department are the works illustrating the origin and antiquities of the aboriginal tribes of America, the most important of which are the elaborate series by H. R. Schoolcraft, and more particularly his "Historical and Statistical Information" previously mentioned; the "American Antiquities and Researches into the Origin of the Red Race," by A. W. Bradford; the "Ancient Monuments of the Mississippi Valley," by E. G. Squier and E. H. Davis; the "Aboriginal Monuments of the State of New York," and the "Serpent Symbol," by E. G. Squier; "Prehistoric Races of the United States," by J. W. Foster; "The Native Races of the Pacific States," by H. H. Bancroft, a work of great research and erudition, and almost of an exhaustive character; "The Myths of the New World," by D. G. Brinton; "Ancient America," by J. D. Baldwin, author also of "Prehistoric Nations;" and various writings by Albert Gallatin, J. L. Stephens, W. W. Turner, G. Catlin, and others.—The number of works devoted to travel and exploration is vastly in excess of that of either of the preceding periods. Among those illustrating European travel and scenery are "Pleasant Memories of Pleasant Lands," by Mrs. Sigourney; "The Old World and the New," by Orville Dewey; "Letters from Abroad," by Miss Sedgwick; "A Year in Spain" and "Spain Revisited," by A. S. Mackenzie; "Pencillings by the Way," by N. P. Willis; "The Pilgrim in the Shadow of Mont Blanc," by G. B. Cheever; "Six Months in Italy," by G. S. Hillard; "Views Afoot" and other works by Bayard Taylor (born 1825), one of the most active and entertaining of modern travellers; "Sunny Memories of Foreign Lands," by Mrs. Stowe; "Hungary in 1851," "Home Life in Germany," and "The Norse Folk," by C. L. Brace; and many by Benjamin Silliman, W. C. Bryant, William Ware, Caleb Cushing, H. T. Cheever, J. T. Headley, Calvin Colton, Pliny Miles, S. I. Prime, Horace Greeley, H. T. Tuckerman, J. A. Dix, S. S. Cox, Mrs. Kemble, Mrs. Octavia W. Le Vert, Miss A. C. Johnson, and others. The most noticeable books upon Asia and Africa are the two series of "Biblical Researches in the Holy Land," by Edward Robinson; "Travels in Egypt, Arabia Petræa, and the Holy Land," by J. L. Stephens; "The Land and the Book," by W. H. Thomson; "The Pathways and Abiding Places of Our Lord," by J. M. Wainwright; "Nile Notes of a Howadji" and "The Howadji in Syria," by G. W. Curtis; "Boat Life in Egypt and Nubia" and "Tent Life in the Holy Land," by W. C. Prime; "Yusef," by J. Ross Browne; "The Middle Kingdom," by S. Wells Williams; "Domestic Life of the Chinese," by Justus Doolittle; "W. H. Seward's Travels round the World;" Pumpelly's "Across America and Asia;" Henry M. Stanley's "How I found Livingstone;" and H. J. Van Lennep's "Pictures of Bible Lands;" besides others by Bayard Taylor, W. Colton, Horatio Southgate, Stephen Olin, S. I. Prime, R. B. Minturn, and Frank Vincent, jr. Among books of maritime adventure or travel are W. S. W. Ruschenberger's "Voyage round the World" and "Three Years in the Pacific;" R. H. Dana, jr.'s "Two Years before the Mast;" Walter Colton's "Deck and Port," and other works; H. T. Cheever's "Island World of the Pacific;" H. A. Wise's "Los Gringos;" Herman Melville's "Redburn" and "White Jacket;" and Charles Nordhoff's "Man-of-War Life," and other highly graphic narratives of a similar character. Of works relating to the United States, the most important are Irving's "Astoria" and "Tour on the Prairies," which in point of style and interest are not inferior to anything he wrote; Timothy Flint's "Residence and Wanderings in the Valley of the Mississippi;" the various narratives of travel on the upper Mississippi by Schoolcraft; Bayard Taylor's "El Dorado;" the accurate and graphic "Journey in the Seaboard Slave States," "Journey through Texas," and "Journey in the Back Country," by F. L. Olmsted; "Picturesque America," a richly illustrated work, edited by W. C. Bryant; and many by George Catlin, G. W. Kendall, J. T. Headley, T. B. Thorpe, Horace Greeley, C. W. Webber, Sidney Andrews, and others. The geography and antiquities of Central America have been elaborately described by J. L. Stephens in his "Travels in Central America" and "Incidents of Travel in Yucatan;" by E. G. Squier in his "Nicaragua" and "Notes on Central America;" and by B. M. Norman in his "Ruined Cities of Yucatan." Among other works relating to the American hemisphere are F. F. Holton's "New Granada;" C. S. Stewart's "Brazil and La Plata;" Thomas Ewbank's "Life in Brazil;" "Brazil and the Brazilians," by D. P. Kidder and J. C. Fletcher; John Bigelow's "Jamaica in 1850;" R. B. Kimball's "Letters from Cuba" and "Cuba and the Cubans;" W. H. Hurlbert's "Gan Eden, or Pictures of Cuba;" R. H. Dana, jr.'s "To Cuba and Back;" F. S. Cozzens's "Acadia;" Agassiz's "Journey in Brazil;" C. F. Hartt's "Geology and Physical Geography of Brazil;" and James Orton's "The Andes and Amazon." A peculiar and important class of books of travel has resulted from the explorations undertaken at various times by the United States government, with a view of adding to the general stock of geographical knowledge, or of developing the resources of its own territory. The most elaborate of these is the "Narrative of the United States Exploring Expedition around the World," by Capt. Charles Wilkes, in five volumes; and of not less importance to the cause of geographical science are the narratives of exploration among the Rocky mountains and in Oregon and California by J. C. Fremont; the reports of expeditions to the Red river of Louisiana, by Capt. R. B. Marcy; to Texas and New Mexico, by J. R. Bartlett; to Utah, by Capt. Howard Stansbury; to Arizona and the Gila river, by Lieut. Col. W. H. Emory; to the southern hemisphere, by Lieut. J. M. Gilliss; to Japan, by Commodore M. C. Perry; to the Rio de la Plata, by Lieut. T. S. Page; to the Amazon, by Lieuts. W. L. Herndon and L. Gibbon; to the Dead sea, by Lieut. W. F. Lynch; and the reports of the various expeditions for the survey of railroad routes to the Pacific. The chief arctic explorers are Elisha Kent Kane (1820–'57), whose narratives of the two Grinnell expeditions in search of Sir John Franklin are among the most interesting works of their class yet produced; I. I. Hayes, author of "An Arctic Boat Journey," "The Open Polar Sea," and other works; and C. F. Hall, author of "Arctic Researches," whose melancholy fate is recorded in the "Arctic Experiences of Capt. G. E. Tyson," edited by E. V. Blake.—The wide field of natural history has been explored during this period with results highly creditable to the sagacity and industry of American men of science. The most important work in this department is the "Birds of America," by John James Audubon (1780–1851), remarkable for the vivacity of its descriptive passages and its splendid illustrations. American zoölogy has been further treated by Charles Lucien Bonaparte, Thomas Nuttall, J. P. Giraud, John Cassin, S. F. Baird, T. M. Brewer, and Elliott Coues, who have written on ornithology; by D. H. Storer, S. L. Mitchill, J. E. De Kay, and Le Sueur, on ichthyology; by Louis Agassiz, whose publications on comparative embryology, ichthyology, the geographical distribution of animals, and analogous subjects, are of the highest order of merit; by J. E. Holbrook, author of the most complete work on North American herpetology yet published; by Thomas Say, T. M. Harris, A. S. Packard, C. V. Riley, and J. L. Le Conte, who have written on entomology; and by Zadoc Thompson, A. A. Gould, B. S. Barton, T. A. Conrad, J. D. Dana, Isaac Lea, Jeffries Wyman, J. Bachman, J. E. De Kay, J. D. Godman, V. G. Audubon, S. Kneeland, A. E. Verrill, E. S. Morse, A. Agassiz, and others, who have illustrated various branches of the subject. The most eminent writers on botany are Asa Gray, author of several valuable elementary works and manuals; John Torrey, who prepared, sometimes in conjunction with Gray, the botanical reports of most of the United States exploring expeditions; Amos Eaton, Stephen Elliott, C. S. Rafinesque, Thomas Nuttall, W. Darlington, A. B. Strong, Jacob Bigelow, D. J. Browne, Alphonso Wood, W. S. Sullivant, and George Thurber; on geology, President Edward Hitchcock, William Maclure, W. B. and H. D. Rogers, J. G. Percival, Ebenezer Emmons, T. Sterry Hunt, C. T. Jackson, D. D. Owen, J. D. Whitney, A. Winchell, F. V. Hayden, J. P. Lesley, C. F. Hartt, Clarence King, J. W. Foster, W. C. Redfield, C. H. Hitchcock, J. S. Newberry, James Hall, Joseph Leidy, H. C. Lea, W. W. Mather, O. C. Marsh, and C. D. Cope, of whom the last seven are also distinguished as palæontologists; and on mineralogy, Prof. J. D. Dana, author of several works on both geology and mineralogy, J. Ross Browne, P. Cleaveland, L. C. Beck, and C. U. Shepard. The writers on chemistry include Benjamin Silliman and Benjamin Silliman, jr., Robert Hare, C. T. Jackson, J. W. Draper, Joseph Henry, E. N. Horsford, John Torrey, E. L. Youmans, Campbell Morfit, and J. P. Cooke, jr. In other branches of natural science the most noted names are M. F. Maury, author of the "Physical Geography of the Sea" and other works, W. C. Redfield, J. P. Espy, and John Brocklesby, distinguished as meteorologists; J. W. Bailey, an eminent microscopist; A. D. Bache, for many years superintendent of the United States coast survey; Joseph Henry, who has made important discoveries in electro-magnetism; Samuel Forry and Lorin Blodget, climatologists; A. M. Mayer, distinguished for researches in acoustics; and S. C. Walker, B. A. Gould, G. P. Bond, O. M. Mitchel, Denison Olmsted, J. M. Gilliss, Hannah M. Peterson, Maria Mitchell, W. A. Norton, Elias Loomis, Joseph Winlock, D. Kirkwood, Simon Newcomb, C. H. F. Peters, J. C. Watson, T. H. Safford, S. P. Langley, and C. A. Young, distinguished chiefly as astronomers. The most eminent mathematician whom the country has yet produced is Nathaniel Bowditch (1773–1838), author of a translation, with a commentary, of Laplace's *Mécanique céleste*, and of the well known "Practical Navigator," now in almost universal use. Other writers on mathematics are Benjamin Peirce, Charles Davies, C. H. Davis, and Thomas Hill. Many of the above named have been contributors to the reports and publications of the Smithsonian institution, or have participated in the scientific labors of the United States exploring expeditions and similar undertakings. —Of the numerous works on medicine and surgery produced during this period, it will suffice to mention the "Treatise on the Practice of Medicine," by G. B. Wood; "Dispensatory of the United States," by G. B. Wood and F. Bache; "Elements of Medical Jurisprudence," by J. B. and T. Romeyn Beck; "Elements of Pathological Anatomy," by S. D. Gross; "Materia Medica and Therapeutics," by J. Eberle; "The Principles of Surgery," by W. Gibson; "The Elements of Medicine," by S. H. Dickson; "The Institutes of Medicine," by Martyn Paine; the treatises on "Midwifery" and "Diseases of Females," by W. P. Dewees; the treatise on "Obstetrics," by C. D. Meigs; the "Human Physiology" and "Dictionary of Medical Science," by R. Dunglison; "American Medical Botany" and "Nature in Disease," by Jacob Bigelow; "Letters to a

Young Physician," by James Jackson; "Surgical Observations on Tumors," by J. C. Warren; the treatises on "Human Physiology" by J. W. Draper and by J. C. Dalton; the "Treatise on the Principles and Practice of Medicine," by Austin Flint; "The Physiology of Man," by Austin Flint, jr.; and the various works of W. A. Hammond; besides which there are many of reputation by D. Hosack, J. W. Francis, S. G. Morton, S. Forry, J. Bell, P. Earle, O. W. Holmes, G. S. Bedford, Horace Green, C. A. Harris, W. E. Horner, P. S. Physick, C. Wistar, Valentine Mott, J. Pancoast, L. V. Bell, W. W. Sanger, A. Brigham, L. M. Lawson, S. W. Mitchell, T. D. Mütter, Bennet Dowler, J. A. Swett, Daniel Drake, Charles Caldwell, H. H. Smith, E. Parrish, J. King, A. Stillé, Winslow Lewis, G. Hayward, J. M. Smith, P. Townsend, W. W. Gerhard, J. R. Cox, P. F. Eve, S. F. Condie, and W. H. Van Buren. The principal writers of the homœopathic school are C. Hering, E. E. Marcy, J. H. Pulte, C. J. Hempel, Egbert Guernsey, and W. H. Holcombe.—The theory of education has occupied a large share of the attention of American writers during this period; and among many valuable works on the subject may be mentioned the "Lectures on Education," by Horace Mann (1796–1859); "National Education in Europe," by Henry Barnard; "The Theory and Practice of Teaching," by D. P. Page; "The Student's Manual," by John Todd; "University Education," by Chancellor H. P. Tappan; "The School and Schoolmaster," by Bishop Alonzo Potter and G. B. Emerson; besides others by F. A. P. Barnard, William Russell, Barnas Sears, G. F. Thayer, W. A. Alcott, W. C. Woodbridge, Hubbard Winslow, A. B. Alcott, W. H. McGuffey, J. S. Hart, and S. G. Howe. Under this head may also be included the "Five Years in an English University," by C. A. Bristed; "German Universities," by J. M. Hart (also treated in J. F. Hurst's "Five Years' Residence in Germany"); and "American Colleges" and other works by Noah Porter. The general excellence and enormous production of school books are perhaps the most remarkable features of American literature. Among these are the Greek lexicons of J. Pickering and H. Drisler; the Latin lexicons of F. P. Leverett and E. A. Andrews; the Latin and Greek grammars and elementary books of Andrews, C. C. Felton, Charles Anthon, J. McClintock, A. C. Kendrick, J. Hadley, J. R. Boise, A. Crosby, A. Harkness, E. A. Sophocles, P. Bullions, and S. H. Taylor; and the editions of classical authors by President T. D. Woolsey, Anthon, Felton, H. S. Frieze, T. A. Thacher, Tayler Lewis, J. J. Owen, J. L. Lincoln, C. S. Wheeler, and C. K. Dillaway. English grammar and composition have been treated by Samuel Kirkham, Goold Brown, J. Greenleaf, P. Bullions, W. H. Wells, Allan Weld, R. G. Parker, G. P. Quackenbos, William Swinton, and others; and the spelling books of Noah Webster, C. W. Sanders, and S. Town have had a prodigious circulation. The chief writers of mathematical text books are Daniel Adams, Warren Colburn, C. W. Hackley, C. Davies, W. G. Peck, E. Loomis, G. R. Perkins, T. Sherwin, B. Greenleaf, F. Emerson, D. Leach, W. M. Gillespie, W. D. Swan, and J. F. Stoddard; and of school geographies, atlases, etc., W. C. Woodbridge, Mrs. Emma Willard, Jesse Olney, J. E. Worcester, R. C. Smith, S. A. Mitchell, F. McNally, Arnold Guyot, Miss S. S. Cornell, and William Swinton.—Among works on the science of war may be mentioned those on military tactics by Lieut. Gen. Winfield Scott (1786–1866) and W. J. Hardee; A. Mordecai's "Artillery for the United States Land Service;" D. H. Mahan's works on engineering, fortifications, &c.; H. W. Halleck's "Elements of Military Art and Science;" J. A. Dahlgren's "System of Boat Armament" and "Shells and Shell Guns;" C. B. Stuart's "Naval Dry Docks of the United States;" J. G. Barnard's "Notes on Sea-coast Defence;" J. H. Ward's "Elementary Course of Instruction in Ordnance and Naval Gunnery;" De Hart's "Constitution and Practice of Courts Martial;" Col. H. L. Scott's "Dictionary of Military Science;" Upton's "New System of Infantry Tactics;" besides many by J. G. and B. J. Totten, E. L. Viele, W. N. Jeffers, jr., H. D. Grafton, J. G. Benton, Hermann Haupt, A. L. Holley, S. V. Benét, H. D. Wallen, A. J. Meyer, E. C. Boynton, and others.—Comparatively few authors have written on the fine arts; the most prominent are W. Dunlap, author of a "History of the Arts of Design in America;" J. J. Jarves, author of "Art Hints" and "Art Thoughts;" Washington Allston, Horatio Greenough, H. T. Tuckerman, B. J. Lossing, W. H. Fry, Mrs. H. F. Lee, Thomas Hastings, W. M. Hunt, and Lowell Mason, who have written upon sculpture, painting, and music. Rural architecture and landscape gardening have been illustrated by A. J. Downing (1815–'52) in a number of gracefully written treatises and essays; and Samuel Sloan, C. Vaux, G. Wheeler, T. W. Walter, R. Upjohn, M. Field, and others have published general works on architecture. Of the numerous works produced on agricultural and horticultural subjects may be cited "European Agriculture and Rural Economy," by H. Colman; the "Farmer's Companion" and "Farmer's Instructor," by Jesse Buel; E. Ruffin's "Calcareous Manures;" R. L. Allen's "American Herd Book" and "New American Farm Book;" R. Buist's "American Flower Garden Directory;" Downing's "Fruit and Fruit Trees of America;" "The Fruit Garden," by P. Barry; "The Fruit Trees of America," by C. M. Hovey; "The Muck Manual," by S. L. Dana; H. S. Randall's "Sheep Husbandry;" L. T. Smith's "American Farmer's Hand-Book;" G. E. Waring's "Elements of Agriculture;" J. J. Thomas's "Farm Implements and Machinery;" besides many valuable publications by J. S. Skinner, C. L. Flint, J. J. Mapes, S. W. Johnson, D. J. Browne, T. Bridgman, W. Gaylord, L. Tucker, G. H. Dodd, J. Harris, H. S. Olcott, and others. The useful manuals of Mrs. Hale, Miss C. E. Beecher, Miss Leslie, and Mrs. Terhune represent the contributions to domestic economy. J. R. Snowden and W. C. Prime are the principal writers on numismatics; E. Jarvis, L. Shattuck, J. Chickering, J. D. B. De Bow, and F. A. Walker represent the statisticians; James Renwick and Thomas Ewbank the writers on mechanics; H. W. Herbert has a unique reputation as a writer on field sports in America; and C. E. Lester has been a prolific miscellaneous author. Among the miscellaneous literature of the period may be classed the numerous volumes of "Collections" and "Memoirs" illustrating the national history, published by the historical societies of the several states, particularly by those of Massachusetts, New York, and Pennsylvania. The "Archæologia Americana," or transactions of the American antiquarian society, form also a valuable contribution to the archæological literature of the country. Lastly, the foundations of American bibliography have been laid by the valuable works of Isaiah Thomas, O. A. Roorbach, G. P. Putnam, Nicholas Trübner, H. E. Ludewig, H. Ternaux, H. Stevens, O. Rich, E. B. O'Callaghan, F. Leypoldt, and Joseph Sabin. (See NEWSPAPERS, and PERIODICALS.)

UNIVERSALISTS, a religious denomination, holding the final destruction of evil, and the restoration of all souls through Jesus Christ. The following statement probably represents the belief of the great majority of Universalists of the present day. I. OF GOD. They believe that God is infinite in all his perfections, creating man with the fixed purpose that the existence he was about to bestow should prove a final and everlasting blessing; that, foreseeing all the temptations, transgressions, and struggles of man, he shaped his government, laws, and penalties with express reference to these emergencies, and adapted the spiritual forces to the final overcoming of all evil; that being almighty, he can convert and save a world of sinners as easily as he converted and saved Saul of Tarsus or Matthew the publican, and without any more violation of "free agency" in the one case than in the other. They also believe in the perfection of the divine justice; and affirm, on this ground, that God would not impose on finite beings a law infinite in its demands and penalties; but that, being perfectly just, he will deal with every man according to his works, whether good or bad. II. OF CHRIST. They uniformly reject the doctrine of the Trinity, making Christ subordinate to the Father. They believe that he is gifted with spirit and power above all other intelligences; that he is "God manifest in the flesh," *i. e.*, that God has displayed in him the brightness of his glory and the express image of his person, as in no other being tabernacled in flesh; that he was sent of God to be the Saviour of the world, and that he will actually save it, because God would not offer, nor would Christ accept, a mission which both knew would end in failure; therefore, they say, the work of redemption will be thorough and universal. III. OF MAN. They believe that Adam was created upright, but liable to sin; that all men are formed, as Adam was, in the moral image of God; and that this image, though it may be disfigured by sin, can never be wholly lost. Faith and regeneration remove the stains and defilements of sin, and renew or reform the soul in the divine likeness. IV. OF REGENERATION. They believe the new birth to be that thorough change of heart which takes place when a man, wrought upon by divine truth and grace, forsakes his sins, or turns from his former life of worldliness and indifference toward God and the Saviour, and is drawn into fellowship with the Holy Spirit, and, thus quickened into new spiritual vitality, consecrates himself to a life of active goodness and piety. This new birth is not supernatural, but the result of appointed means suitably improved. The Holy Spirit blesses the use of these means, and moves upon the heart of the sinner, encouraging, comforting, assisting, sanctifying. They do not believe in instantaneous regeneration, though they teach that there may be a turning point in the life of every man, when his attention is specially directed to religion. Conversion is only the commencement of religious effort. V. OF SALVATION. They teach that salvation is not shelter nor safety, nor escape from present or future punishment. It is inward and spiritual, and not from any outward evil, but deliverance from error, unbelief, sin, the tyranny of the flesh and its hurtful lusts, into the liberty and blessedness of a holy life, and supreme love to God and man. This is an important doctrinal and practical point with Universalists, and is constantly enforced in their preaching and writings. They urge on all to seek salvation, not from the torments of a future hell, but from the present captivity of sin. In reply to the objection that millions die in sin, in pagan ignorance and unbelief, they answer that no one is wholly saved in this life, but that all men are saved, in a greater or less degree, after death; and assert that the power of Christ over the soul does not cease with the death of the body, but that he continues the work of enlightenment and redemption till he surrenders the kingdom to the Father, which does not take place till after the resurrection is complete. VI. OF THE RESURRECTION. The resurrection is not merely a physical but a moral and spiritual change. It is not only clothing the soul with an incorruptible body, but it is an *anastasis*, a raising up, an exaltation of the whole being into the power and glory of the heavenly; for, "as we have borne the image of the earthy, we shall also bear the image of the heavenly." It is a change, they say, by which we become as the angels, and "are children of God, being (or, because we are) children of the resurrection." It must, therefore, be something more than clothing the soul in a spiritual body. It is, besides this, growth in spiritual strength and power, in knowledge, in holiness, in all the elements and forces of the divine life, until we reach a point of perfectness and blessedness described by the term heaven. This resurrection, or lifting up of the soul into the glorified life of the angels, is the work of the Lord Jesus Christ. The end of his mediatorial reign, the completion of his saving work, and the final surrender of his kingdom back to God, does not take place till after this anastasis, or till this uplifting of all the dead and living into "the image of the heavenly" is completed. VII. Of Rewards and Punishments. On the subject of rewards and punishments, the Universalist belief is substantially, that holiness, piety, love of God and man, are their own reward, make their own heaven here and hereafter; and that in the nature of things no other reward is possible. If men love God with all their hearts, and trust in him, they find, and are satisfied with, the present heaven which love and faith bring with them. They hold the same doctrine respecting punishment: that it is consequential, not arbitrary—the natural fruit of sin; that it is for restraint, correction, and discipline; and that God loves as truly when he punishes as when he blesses, never inflicting pain in anger, but only because he sees that it is needed to prevent a greater evil. They affirm that the law is made for the good of man, and that of course the penalty cannot be such as to defeat the object of the law. Transgression brings misery or punishment, which is designed to correct and restore to obedience, because obedience is happiness. They maintain that pain ordained for its own sake, and perpetuated to all eternity, is proof of infinite malignity; but God, they say, is infinitely beneficent, and therefore all suffering must have a beneficent element in it, all punishment must be temporary and end in good.—The Universalists believe that traces of their main doctrine may be found in the earliest Christian writings. Some of the Gnostic sects held to the final purification of those who died in sin, as the Basilidians, Valentinians, &c. The famous Christian collection known as "Sibylline Oracles" teaches explicitly the doctrine of the final restoration of the lost. As this work was written expressly to convert the pagans to Christianity, Universalists affirm that this is conclusive as to what was regarded as Christian doctrine on this point in the earliest period of Christianity. They profess to find the same belief taught in the writings of Clement of Alexandria, Origen, Marcellus of Ancyra, Titus of Bostra, Gregory of Nyssa, Didymus the Blind of Alexandria, Diodorus of Tarsus, Theodore of Mopsuestia, and Fabius Marius Victorinus (A. D. 200–400). Notwithstanding that Universalism, as such, was specially and formally condemned by a council, that of Mennas, held in Constantinople, A. D. 544, the doctrine survived, and occasionally appeared in strength; as among the Albigenses and Waldenses in the 12th century, the Lollards of Germany in the 14th, the "Men of Understanding" in the 15th, and some of the Anabaptist sects in the 16th. When the reformation began in England, this doctrine rose with it, and was defended with such zeal and success that, in preparing the "Articles of Faith" for the national church, it was thought necessary to introduce a special condemnation in an article which afterward, when the forty-two articles were revised and reduced to thirty-nine, was omitted. Some of the most eminent members of this church have sanctioned the doctrine: Archbishop Tillotson, Dr. Burnet in his *De Statu Mortuorum*, Bishop Newton, Dr. Henry Moore, William Whiston, David Hartley in his "Observations on Man," and others. Among others who believed and defended it were Soame Jenyns, Jeremy White, chaplain to Oliver Cromwell and author of "The Restoration of All Things," and William Law, author of the "Serious Call" and "Christian Perfection." The English Unitarians generally believe the doctrine; and it is held by numbers in the established church, and positively taught in their writings, as in those of Charles Kingsley, Stopford Brooke, and George Macdonald. The doctrine prevails extensively in Germany. It is freely accepted also in the liberal branch of the French Protestant church. Universalism began to attract attention in America about the middle of the 18th century, and since the arrival of the Rev. John Murray in 1770 it has spread with great rapidity. The denominational "Register" for 1876 gives a United States convention, composed of 22 state conventions, in their turn composed of 73 associations, representing 689 ministers, 867 parishes owning 623 church edifices, and having 628 Sunday schools with a membership of 58,000. The church property is estimated at over $7,500,000 above all liabilities. They have established and supported 5 colleges, 2 theological schools, 7 academies, and 13 periodicals. There are also various state missionary, Sunday school, and tract societies. The woman's centenary association alone distributed nearly a quarter of a million tracts in 1875. The Universalist publishing house at Boston, denominational property, owns the title, copyright, and plates of 125 volumes, and issues five periodicals. The Murray centenary fund, established in 1869 as a memorial of the first century of Universalism in America, devoted to the education of young men for the ministry, the circulation of denominational literature, and church extension, amounted in 1875 to $120,700. Tufts college, at Medford, Mass., opened in 1854, has now a property of over $1,000,000; St. Lawrence university, Canton, N. Y., $255,000; Buchtel college, Akron, Ohio, $300,000; and

Dean academy, Franklin, Mass., $350,000. Relief funds, in aid of aged and needy clergymen and their families, amount to $47,000. The ecclesiastical government of the denomination is representative and congregational, the United States convention being the final court of appeal in all cases of fellowship and discipline. —See Ballou's "Ancient Universalism" (edition of 1872), Whittemore's "Modern Universalism" (1830), Thayer's "Theology of Universalism," &c.

UNIVERSITY (Lat. *universitas*), a corporation, consisting of the teachers or students, or teachers and students, of an educational institution, empowered to confer degrees in one or more faculties. The word *universitas* denoted primarily an aggregate of persons or things; in its secondary sense it was used to designate a society or corporation, but without necessarily any reference to education. Thus there were in Rome universities of priests, musicians, bakers, &c. In the beginning of the middle ages institutions of learning were called *schola*, *studium*, or *studium generale*, and afterward *universitas magistrorum*, *doctorum*, or *scholarium*. The university of Paris was a corporation of teachers, that of Bologna of students, while Salamanca partook of both characteristics. The remainder of the Italian and nearly all of the French universities were also associations of students, but the English and German universities were modelled after that of Paris.—The modern university, which had no exact counterpart in the ancient academies, had its origin in the schools which grew up around the monasteries and cathedrals of Europe. These began about the 6th century, and took the place of the Roman imperial schools which had fallen with the irruptions of the barbarians, but previous to the reign of Charlemagne they were of little importance. That emperor called around him learned men from all countries, and established cathedral and conventual schools in his principal cities; under his successors these became centres of learning, in which was taught all the erudition of the age. The fame of some successful teacher in any of these schools attracted thither other lecturers and many students, who in time formed unions or associations for mutual benefit, and thus laid the foundations of the universities. The oldest of these, the university of Paris, owed its early celebrity to the teachings of William of Champeaux, who taught logic in Paris in 1109, and of Abélard, his pupil and rival. Peter Lombard, a student of Bologna and afterward of Paris, taught theology there in the same century, and added to its reputation; and it is said that its students in 1150 exceeded the citizens in number. These were connected with many different schools, some of which were appendages of the churches and monasteries in and around Paris, and some private schools gathered around noted lecturers. Toward the end of the 12th century all were formed into a corporate body by Philip Augustus, but it does not appear that the term university was applied to it before the beginning of the 13th century. It is probable that it had formed several organizations previous to this consolidation; for the students of the arts and sciences were divided as early as 1169 into four provinces or nations: the French nation, including, besides French, natives of Spain, Italy, and Greece; the Picard, students from N. E. France and the Netherlands; the Norman, those from W. France; and the English (called German after 1430), those from England, Ireland, Scotland, and Germany. Each nation was governed by a procurator. The university comprised at first but two faculties, that of arts and sciences, and that of theology; law and medicine were added in the 13th century. Each faculty, excepting that of arts and sciences, had at its head a dean, and the three deans and the four procurators constituted a council, in which, under the presidency of the rector, who was elective, was vested the government of the university. The power of conferring degrees belonged to the chancellor alone. There were two chancellors, one appointed by the bishop of Paris, and one by the abbot of Ste. Geneviève, in whose lands were situated a part of the university buildings; the former, who took precedence, was chancellor of the three higher faculties, the latter of the faculty of arts. Academic degrees were conferred as early as the middle of the 12th century, and probably before, but their origin is unknown. At first the degree of master was synonymous with that of doctor, and was conferred on those who were competent to teach; but afterward the former was confined to those who taught the arts, and the latter to those who gave instruction in theology, law, or medicine. Bachelors were those who had passed through the curriculum of study, which required three and a half years; after a second equal period of study and the passing of the requisite examinations, they became masters and were qualified to teach the seven liberal arts within the limits of the university. Pope Nicholas I. gave the university the power of endowing its graduates with the privilege of teaching everywhere. For the doctor's degree in divinity nine years' additional study was required. As many of the thousands of students who annually flocked to Paris were poor, colleges were early established by individuals and by religious orders, where at first free board and lodging only were dispensed; but many of them finally became places of instruction also. Toward the close of the 15th century there were 18 large colleges belonging to the faculty of arts, and 80 smaller ones. At this time nearly all students belonged to some of the colleges. Those who were unattached to any were called *martinets*. (See College.) The university of Paris was endowed with extraordinary privileges, and was so powerful that it sometimes resisted even the royal authority. It did not acknowledge the jurisdiction of ordinary judges, but had its own courts and its representatives in the states general. During the wars of the league it lost its political importance, and in 1793, by a decree of the convention, it was suppressed. Napoleon I., by the law of 1806 and the decrees of 1808 and 1811, established a national organization embracing all public instruction under the name of the university of France, at the head of which was a grand master assisted by a university council. This comprised several sections called academies, each embracing several departments, and each governed by a rector assisted by an academical council. This great institution monopolized all higher instruction until 1875, when the law permitting the establishment of universities independent of the state was passed. But the university of France is still maintained, and in 1875 had subordinate to it 16 academies, with the following centres: Aix, Besançon, Bordeaux, Caen, Chambéry, Clermont, Dijon, Douai, Grenoble, Lyons, Montpellier, Nancy, Paris, Poitiers, Rennes, and Toulouse. A complete academy, like that of Paris, has the five faculties of theology, law, medicine, science, and letters; but most of the other provincial centres have only three or four faculties. The academy of Paris has a very large corps of professors and usually from 7,000 to 8,000 students. The provincial academies average about 1,500 students. The university of France, which alone has the power to confer degrees, is now under the direct control of the minister of education. A new Roman Catholic university was projected in Paris in 1875. The other universities of France, all of which were suppressed with that of Paris in 1793, and some of which were afterward reëstablished as academies, were as follows: Montpellier, celebrated as a medical school, founded in 1176; Toulouse, famous as a school of law, 1228; Angers, 1246; Lyons, 1290; Orleans, 1309; Grenoble, 1339, removed to Valence in 1452; Avignon and Perpignan, 1340; Orange, 1365; Aix, 1409; Dôle, 1422, removed to Besançon in 1676; Poitiers, 1431; Caen, 1433; Bordeaux, 1441; Valence, 1452; Nantes, 1463; Bourges, 1463; Rheims, 1547; Douai, 1568; Besançon, 1676; Pau and Dijon, 1722; Nancy, 1769.—Of nearly equal antiquity with the university of Paris is that of Bologna, which attained fame as a law school under Irnerius early in the 12th century. Some writers have endeavored to connect it with a school established there in the 5th century by Theodosius II. and revived by Charlemagne, but it had no claim to be called a university before the 12th century. A similar claim of the university of Pavia to have been founded by Charlemagne in 774 rests on no better foundation. Bologna was granted a charter of privileges in 1158 by Frederick Barbarossa. The students were divided into two universities, *citramontani* or natives of Italy, and *ultramontani* or foreigners, the former divided into 17 and the latter into 18 nations. Each nation had a presiding officer called a counsellor, except the German, which had instead two procurators. Toward the close of the 12th century rectors were chosen, one for each university, by the combined votes of the counsellors and of electors chosen from the university at large. For a long time the students of arts and of medicine were enrolled in the university of law, and it was not till 1316 that their right to form a separate university was acknowledged. A university of theology was established in 1362, the members of which were all doctors, the students being enrolled among the scholars of art. Degrees were conferred at Bologna at a very early period. The first teachers were called *dominus*, *magister*, *causidicus*, and *judex*. Eight years' study was required for the degree of doctor of civil law, and six years' for that of canon law. These degrees were conferred upon learned men and women alike, and the latter were even permitted to hold professorships until a late period. Fixed salaries were paid to professors at Bologna as early as the 13th century, and in the 17th century the city expended annually about 40,000 crowns in salaries. The university of Salerno was as celebrated in medicine as that of Paris in theology and science, and that of Bologna in law. It attained its greatest fame in the 12th century, although it existed as a school several centuries earlier. Students were obliged to study logic for three years in this university before beginning the study of medicine, which occupied them five years longer, and they were not then admitted to a degree until they had practised for a year under a skilled physician. As at Bologna, women as well as men were admitted to the privileges of the university, and in the 11th, 12th, and 13th centuries several of its female graduates were noted as physicians and as writers of medical treatises. (See MEDICINE, vol. xi., p. 348.) Of the present Italian universities, those classified in the accompanying table are royal universities, maintained by the government. In these the faculty of theology has been abolished by act of parliament, and women are admitted as students in all the faculties. The university of Rome is known as the Collegio della Sapienza. Four other universities, Camerino (founded in 1727), Perugia (1307), Ferrara (1321), and Urbino (1671), are maintained by their respective provinces. The following universities, some of which were once flourishing institutions, no longer exist: Vicenza (founded 1204), Arezzo (1215), Vercelli (1228), Piacenza (1248), Cremona (1413), Florence (1438), Milan (1565), and Mantua (1625).—Next after Paris and Bologna, the universities of Oxford and Cambridge became celebrated. About 1200 the great French and Italian schools were largely resorted to by English students; but by the middle of the 13th century Oxford was second only to Paris in the number of its students and the brilliancy of its scholarship. Its students were never divided into nations, but were governed as one body under a chancellor. In the 13th century three colleges were established, and in the 14th these were increased to seven, and most of the students were enrolled in one or the other of them. The government of Cambridge was similar to that of Oxford, and colleges were established there about the same period. (See CAMBRIDGE, UNIVERSITY OF, and OXFORD, UNIVERSITY OF.) The two other English universities, Durham and London, were founded in 1833 and 1836 respectively. The former owes its origin to an effort begun in 1649 and carried into effect in 1657, when letters patent were granted by Cromwell for its establishment, the buildings belonging to the deans and prebendaries of Durham cathedral being set apart for its use. But the restoration put an end to the project, and it was not revived till 1831; in 1832 an act of parliament permitted the appropriation of certain property belonging to the cathedral for the use of the university, which was opened the following year, and in 1837 it was incorporated and granted all the rights and privileges incident to universities created by royal charter. It now has one college, called University college, and two halls, Bishop Hatfield's, founded in 1846, and Bishop Cousin's, founded in 1851. Its general regulations for education are similar to those of Oxford and Cambridge. The university of London was created in 1836 by royal charter, the provisions of which have been several times enlarged and modified. It confers its degrees, with a few exceptions, upon persons educated in any part of the British dominions who can satisfactorily pass its examinations. Unlike the other universities, it has no colleges immediately connected with it, but has affiliated to it nearly all the institutions of learning in the British empire, including Oxford, Cambridge, and Durham, and the Scottish and Irish universities, to the students of all of which its honors are open for competition. No degrees are conferred in course or *pro causa honoris*, but strict examinations are required before each degree. This institution has accomplished much good in rendering education freer from form and routine, and yet more thorough. All the English universities excepting that of London formerly required a declaration of membership in the established church as a qualification for graduation; but by the universities' test act of 1871, no student at Oxford, Cambridge, or Durham is now obliged to subscribe any profession of faith for any degree, or for the exercise of any right of graduates, excepting in divinity.—The universities of Scotland originally differed somewhat from those of England. The students were divided, as in the continental universities, into four nations, named respectively Fife, Angus, Albany, and Lothian, and the colleges were the places of residence of the teachers and not of the students. St. Andrews had from its foundation in 1411 faculties of arts, divinity, and canon law; it now consists of two colleges, one of the arts, called the united college of St. Salvator (founded in 1456) and St. Leonard (1512), which were consolidated in 1747, and the divinity college of St. Mary's, founded in 1537. The united college has professors of medicine and chemistry, but the university has no faculties of law and medicine. The university of Glasgow, founded in 1451, was empowered from the beginning to teach theology, civil and canon law, and the arts, but only the faculty of arts was fully organized until after the reformation. It now contains the four usual faculties. The students, who reside without the college walls, are divided into four nations, Glottiana (comprising those from Lanarkshire), Transforthana (Scotland north of the Forth), Rothseiana (Buteshire, Renfrewshire, and Ayrshire), and Londoniana (all other places). The university of Aberdeen was founded in 1494, by a bull of Pope Alexander VI., which granted to it all the immunities and privileges enjoyed by Paris and Bologna. In 1505 a college was founded by Bishop Elphinstone, which was subsequently named King's college. This constituted the entire university till 1593, when Marischal college was founded by George Keith, earl marischal. These two foundations were united by Charles I. under the name of King Charles's university of Aberdeen, but the union seems not to have been recognized, and they retained their character of distinct colleges till 1858, when they were finally incorporated in the present university. King's college now comprises the faculties of arts and divinity, and Marischal those of law and medicine. The students are divided into four nations, Mar, Buchan, Moray, and Angus. The university of Edinburgh, established in 1582 by King James VI., is a single college with the powers of a university. It originally had but one class under a single regent or teacher, but in the beginning of the 17th century it comprised a principal and four regents. Chairs of theology and medicine were instituted in 1642 and 1685 respectively, but there was no faculty of law until the beginning of the 18th century. It was under the direct control of the city corporation till 1858, when a uniform constitution was given to all the Scottish universities by the university act. By this statute each has now three governing bodies, a *senatus academicus*, university court, and general council. The senatus academicus has charge of the instruction and discipline, and of the property and revenues of the university; the university court reviews the decisions of the former body, and regulates the internal affairs of the university; and the general council, a deliberative body, discusses any questions affecting the university, but, having no legislative power, refers them to the university court. The chief officers of each university are a chancellor elected by the general council, a vice chancellor appointed by the chancellor, and a rector elected by the matriculated students. The rectorship is an honorary office, usually conferred upon distinguished non-residents. The degrees conferred on examination are master of arts, bachelor of divinity, of laws, and of medicine, master of surgery, and doctor of medicine; the honorary degrees are doctor of divinity and doctor of laws. Edinburgh grants, besides these, the degrees of bachelor and doctor of science. Bachelor of arts is not now conferred in any of the Scottish universities.—A university was established in Dublin in connection with St. Patrick's cathedral in 1320, by a bull of Pope John XXII., but it was never prosperous. The present university of Dublin was founded in 1591 by Archbishop Loftus, and chartered in the following year by Queen Elizabeth as the college of the holy and undivided Trinity. This, the only college, has all the powers of a university. Its government is vested in a chancellor, a vice chancellor, a provost, a vice provost, and two proctors. The staff of professors is very full, including, in addition to the ordinary faculties, chairs of the oriental and modern languages and mining and civil engineering. The students are divided into four grades: 1, noblemen, sons of noblemen, and baronets, the two first of whom are granted the degree of bachelor of arts *per specialem gratiam;* 2, fellow commoners, who receive the same degree with one examination less than the pensioners; 3, pensioners, who comprise the great body of the students; 4, sizars, who are exempted from annual fees and have their commons free. The sizars are limited to 30, and are selected by competitive examination. Each grade of students wears a distinctive dress. Queen's university consists of three colleges, situated in Belfast, Cork, and Galway respectively, and each called Queen's college. Each college forms a corporate body managed by a council, consisting of the president, vice president, and the four deans of faculty. The university government is vested in a chancellor, vice chancellor, and a senate composed of 20 persons, three of whom are the presidents of the colleges. The seat of the university is in Dublin, the meetings of the senate being usually held in Dublin castle. The Roman Catholic university of Dublin, founded in 1854, has several affiliated colleges.—The Arabs established schools at an early period in Spain, of which those at Cordova, Granada, and Malaga were celebrated before the revival of learning in Christian Europe, but they had little in common with the modern university. The first Spanish university was founded at Palencia in the latter part of the 12th century by Alfonso VIII. of Castile. About 1200 Alfonso IX. of Leon established the university of Salamanca, with which that of Palencia was united in 1239. It received its first endowment in 1254 from Alfonso X., but the country was in so unsettled a state that there was little encouragement for letters, and by 1310 the university had fallen greatly into decay. Spanish students resorted in large numbers to the Italian universities, and many to Paris and Oxford; but toward the close of the 14th century Salamanca became an efficient institution and was attended by upward of 10,000 students. In the 16th century it again declined, and it continued to languish until the French invasion, when most of its fine buildings were destroyed. Salamanca had 28 colleges, of which four were *colegios mayores*, and the remainder *colegios menores.* The former, which were aristocratic foundations and received only students of noble birth, were San Bartolome (1410), Santiago el Cebedeo (1506), San Salvador, and Santiago Apóstolo (1521). These were the only *colegios mayores* in Spain, excepting one at Seville and one at Valladolid, and to be a graduate of one of them was to insure future advancement. They were deprived of their privileges and remodelled in 1770 by Charles III. The *colegios menores* were attended by all students not of noble birth. Besides these there were four military colleges, which ranked with the colleges of the nobles, of the respective orders of San Juan, Santiago, Alcántara, and Calatrava. Only three of these colleges exist in the present university: Santiago Apóstolo, now *el colegio de los nobles irlandeses*, for the education of Irish students for the priesthood; San Carlos Borromeo, one of the *menores*, now the bishop's seminary; and El Carvajal, also one of the *menores*, which is still conducted on its old foundation. Salamanca was governed by a rector assisted by an academic council of which he was the head. All students and graduates were subject to the university judiciary, at the head of which was a special official, the *maestrescuela.* The university comprised schools of all grades; in the *escuelas mayores* the course embraced theology, ecclesiastical and civil law, mathematics, natural and moral philosophy, the languages, and rhetoric; in the *escuelas menores*, grammar and music; and in the *escuelas minimas*, reading, writing, and the elements of grammar. Spain has now ten universities, each of which is intended to have five faculties: philosophy and literature, mathematical and natural sciences, pharmacy, medicine, and law; but they are not all full. Theology is now taught only in the seminaries. The present condition of all the universities is shown in the accompanying table. The following are now extinct: Huesca (founded in 1354), Sigüenza (1471), Ávila (1482), Alcalá de Henares (1510, merged with Madrid in 1836), Toledo (1499), Baeza (1533), and Osuna (1548).—Portugal has but one university, Coimbra, founded at Lisbon in 1291 by Dionysius I., who transferred it to Coimbra in 1308; it was again removed to Lisbon by Alfonso IV. in 1338, and finally established at Coimbra by John III. in 1527. It now embraces 18 colleges, and has five faculties: of theology, of law, of medicine, surgery, and pharmacy, of mathematics, and of philosophy. The rector, who is nominated by the king, presides over the *concelho dos decanos*, which consists of the deans of the faculties and several other officers, and has the general government of the university. Three degrees are conferred: baccalaureate, licentiate, and doctor.—The oldest universities of central Europe, including Germany, are those of Austria, that of Prague having been founded in 1348, of Cracow in 1364, and of Vienna in 1365. The statistics of these and of the other Austro-Hungarian universities are given in the table. In their general organization they are similar to the universities of the German empire, having the four regular faculties; those of theology and philosophy bear the usual designation, but that of law includes political science, and that of medicine is called the medical and surgical faculty. The medical faculty is generally the most prominent, that in the university of Vienna being especially celebrated; but of late years the number of students of law has sometimes exceeded those of medicine. The English rather than the German system of examinations prevails. In 1872 a new university was established in Klausenburg, Transylvania, where one was founded in 1580; and in 1875 one was founded at Czernowitz. Of Austro-Hungarian universities not now existing, that of Tyrnau (founded in 1635) was removed to Buda in 1777, and finally merged in that of Pesth in 1784; that of Trieste (1454) was abolished in 1797; that of Olmütz (1581) was removed to Brünn in 1778, restored to Olmütz in 1827, and abolished in 1853; and that of Salzburg (1620) was abolished in 1810. The school of Linz is not reckoned as a university because it has less than the four faculties.—The present condition of the universities of the German empire is shown in the accompanying table. The governments have supreme control over all of these institutions, the ministers of public instruction having the immediate control; and all are dependent on state appropriations, excepting Leipsic, Heidelberg, and Greifswald, which have property of their own. The government is represented in each by a curator, who is charged with the enforcement of the official regulations and laws; by the professors; and by a quæstor, who collects and pays over the fees due from students. All these officials are appointed by the ministers of public instruction. The professors choose annually the other officers, viz.: a rector, who is the actual head of the university; a pro-rector, who acts as an assistant to the rector in the Austrian universities, but is found in the German universities only when the sovereign is nominal rector, when he performs all the duties of rector; a judge (*Universitätsrichter*) or chancellor (*Kanzler*), who assists the rector in the decision of judicial matters; and the deans (*Dekanen*) of the faculties, who preside over all questions belonging to faculty jurisdiction. The *senatus academicus*, composed of all these officers and several of the ordinary professors, is the legislative body and executive council of the university, but is seldom convened excepting in important cases, the rector and the judge who constitute the university court having jurisdiction over all ordinary matters. All the universities have the four ordinary faculties, to which some add a faculty of political economy (*staatswirthschaftliche*) and of natural science (*naturwissenschaftliche*). Each faculty regulates its own internal affairs through its professors and its dean, subject to the general regulations of the university. Each faculty includes all who teach in its department of instruction, and consists of ordinary or full professors (*ordentliche*); extraordinary professors (*ausserordentliche*), who, though inferior in rank to the ordinary professors, are not necessarily assistants or subordinates; and private lecturers (*Privatdocenten*). In the Austrian universities are also instructors (*Lehrer*) and assistants (*Assistenten*). Entrance into the German universities is to be effected only through the gymnasium, or preparatory school, excepting in the case of foreigners, who are admitted without examination. The examination at the close of the gymnasium course, which is very thorough, is called *Abiturienten-Examen* (leaving examination); the successful student receives a certificate of maturity (*Maturitätszeugniss*), which enables him to enroll himself, after paying a small matriculation fee, as a member of any of the universities, when he registers in whichever faculty he chooses. The course of study is usually four years, but in some of the universities five years are required in the medical faculty. Students are not obliged to remain at one university, but can study at several without loss of standing; they board and lodge where they please, and enjoy much social liberty. Dismission from one university is no bar to entrance at another, but expulsion (*Relegation*) from one is expulsion from all. The principal degree conferred in each faculty is the doctorate, that of philosophy (Ph. D.) corresponding to the English and American A. M. To attain it, an oral examination is required, and a dissertation written in German or Latin. The tendency of the present system of university education in Germany is shown by the great decrease of the number of students in the theological faculties. The Prussian universities (exclusive of those in the territories annexed in 1866), which in 1831 had 2,203 theological students, had but 740 in 1873; Marburg, which had 124 in 1831, had but 46 in 1873; and Giessen, which had 80 in 1850, had only 10 in 1873. The following is a list of German universities which are now extinct, with the dates of their foundation and abolition: Cologne, 1388–1801; Erfurt, 1392–1816; Ingolstadt, 1472, removed to Landshut in 1800, and thence to Munich in 1826; Mentz, 1477–1798; Wittenberg, 1502, merged with Halle in 1815; Frankfort-on-the-Oder, 1506, merged with Breslau in 1810; Dillingen, 1549–1804; Helmstedt, 1575–1809; Herborn, 1584–1817; Paderborn, 1614-1819; Rinteln, 1621–

1809; Altdorf, 1622, merged in 1809 with Erlangen; Münster, 1631, merged in 1818 with Bonn; Osnabrück, 1632–1650; Bamberg, 1648–1803; Duisburg, 1655–1804; Fulda, 1734–1805; Stuttgart, 1781–1794.—The Swiss universities are like the German in almost every respect, but are local rather than national, each being supported by the canton in which it is situated. Instruction is given altogether in the German language, and most of the professors are graduates of German institutions. Their standard is scarcely second rate. Basel, the oldest, was founded in 1460. There were 32 female students at Bern in 1875, and 33 at Zürich.—The universities of Holland are also modelled after those of Germany, but have five faculties, that of philosophy being divided into letters and theoretical philosophy. Instruction is given in great part in the Latin language, and the professors are nearly all ordinary professors. The university of Leyden, founded by William of Orange, became in the 17th century one of the most famous institutions of learning in Europe, and it still retains its high character for scholarship. In 1873 the states general voted 1,300,000 florins for the erection of new buildings and additions to the cabinet collections. The university of Franeker, founded in 1585, was suppressed by Napoleon in 1811. Of the Belgian universities, Louvain, founded about 1425, is the oldest and the most celebrated. In the 16th century it ranked as one of the first institutions of learning in Europe, its students numbered more than 6,000, and it possessed 43 colleges, some of which were munificently endowed. It was suppressed by the French in 1797, reëstablished in 1817 by the Dutch government, again abolished by the Belgian government in 1834, and in 1835 revived as a free Roman Catholic university under the control of the bishops. It now has five faculties: theology, law, medicine, letters and philosophy, and sciences. The universities of Ghent and Liége are state institutions, and each receives from the government 350,000 francs per annum. Each contains four faculties, and Ghent has in addition a school of engineering and Liége a school of mines. They are like the German universities in their general organization, but the examinations for degrees are conducted at Brussels, by a board appointed by the king. The degrees are *candidat* and doctor in each of the faculties. The university of Brussels, founded in 1834 by the liberal party as a rival of Louvain, is free from sectarian bias. It comprises faculties of philosophy, natural science, jurisprudence, and medicine, and a pharmaceutical school. It is controlled by a council of administration, composed of the rector, secretary, and treasurer of the university, with the burgomaster of the city as president. The degree of doctor in any of the faculties is conferred only on those who have been members of the university one year and have received the degree of *candidat*.—The oldest of the Scandinavian universities is that of Upsal in Sweden, founded in 1477 by the regent Sten Sturé. The faculties and teachers are the same as in the German universities, but its general organization is modelled after the mediæval institutions. The students are divided into nations according to the different provinces to which they belong, each nation having a building and officers of its own. The chancellor, pro-chancellor, professors, rector, &c., are all appointed by the king. The rector, who has immediate supervision, is appointed every year. The university of Lund is similar in all respects to that of Upsal, but has never reached its great reputation. The government is about to found a new free university in Stockholm. The university of Christiania, in Norway, is the youngest of the Scandinavian institutions. It is essentially German in organization and government, and has the usual four faculties. The university of Copenhagen, founded in 1478, is the only one now possessed by Denmark, since that of Kiel has been transferred to Germany. It has five faculties: theology, medicine, jurisprudence and political science, philosophy, and mathematical and natural sciences. A rector, chosen yearly, is the executive officer, and its general organization is like that of the German universities.—The Russian universities also are formed on the German model, and many of the professors are German; but only one, Dorpat, has a theological faculty, and the faculty of philosophy is usually divided into a historico-philological and a physico-mathematical faculty. At Kazan there is a division of oriental languages, which is said to be the most complete in the world. Dorpat is noted for its physico-mathematical faculty. The university of Moscow, the oldest established by the Russian government, has a very large and able corps of professors. The Polish university of Warsaw, founded in 1816, was suppressed in 1832, and reëstablished under Russian auspices in 1869. That of Wilna, founded in 1579, and also suppressed in 1832, has not been revived. The Alexander university of Helsingfors, which was removed from Åbo after the burning of its buildings in 1827, still retains much of its former character before it came under Russian influence, and is one of the most progressive institutions in the empire. It has a chancellor, nominally the emperor, but who is represented by the minister for Finland, a vice chancellor, a rector, and a pro-rector. All the Russian universities are sustained mostly by the government. In 1875 a new university was about to be established at Tomsk in Siberia.—The university of Athens was established in 1837, by subscriptions raised mostly from Greeks resident in foreign countries. It is under the supervision of the minister of instruction, but is presided over directly by a rector or vice chancellor. There are four full faculties and a school of pharmacy, and the general system resembles that in the German universities. The university of Corfu, established by the earl of Guilford in 1823, has been suppressed since the union of the Ionian islands with Greece.—A university was established in 1870 in Constantinople, with faculties of literature, law, and the natural sciences and mathematics. It is superintended by a rector, and each faculty has a dean. Roumania has two universities, at Bucharest and Jassy respectively. In Servia the academy of Belgrade was in 1869 erected into a university, which in 1874 had 16 professors and 229 students. The university of Cairo (El-Ashar) is the principal Mohammedan place of education in the East. The instruction includes grammar, arithmetic, algebra, logic, philosophy, and theology and law according to the four sects of the Sunnis. It has more than 300 teachers, and the number of students generally exceeds 9,000. The university of Valetta, Malta, founded in 1838, has faculties of theology, law, medicine, and arts.—The Chinese have a national university (*Kwoh-tsz' Kien*) at Peking, but little is known of its condition. Only the sons of officers of high rank are admitted to its courses, where they are educated at the expense of the government for particular service. The new scheme of education adopted in Japan provides for eight universities, but not all have yet been established. The imperial university in Tokio had in 1875 nearly 100 foreign professors.—India has three universities, at Calcutta, Bombay, and Madras, with each of which are affiliated several colleges. The university of Calcutta has usually from 800 to 1,000 students, and those of Bombay and Madras about 500 each. They are all government institutions. Australia has already three universities, those of Sydney (1852), Melbourne (1854), and Adelaide (1874); and New Zealand has one at Dunedin (1871).—The principal universities of the United States are described in this work in special articles, excepting when the name of the institution coincides with that of the place in which it is situated, when it is treated under that title. (See also COLLEGE, where they are included in the table, and EDUCATION.) The Johns Hopkins university, formally inaugurated in Baltimore on Feb. 22, 1876, will be conducted on the German system. It has an annual income, from the endowment of its founder, of $200,000. The principal Canadian universities are McGill university, in Montreal, founded in 1811, and the university of Toronto in Toronto, founded in 1827. Laval university, a Roman Catholic institution in Quebec, was established in 1852. There are also several other denominational colleges called universities, which are noticed in the articles on the several Canadian provinces.—Most of the South American countries have universities, but few of them have attained eminence. The Argentine Republic has two, at Buenos Ayres and Córdoba. The university of Chili, at Santiago, was founded in 1842, to take the place of that of San Felipe, founded in 1783. It has faculties of law, medicine, pharmacy, and physical and mathematical sciences, and a school of art. Bolivia has three universities, at Sucre, La Paz, and Cochabamba, each of which has faculties of theology, law, medicine, mathematics and physics, and philosophy. They confer degrees of bachelor, licentiate, and doctor in all the faculties excepting medicine, in which only that of doctor is given. Brazil has excellent colleges in Rio de Janeiro, embracing all the faculties, but no established university. There are six universities in Peru, at Lima, Arequipa, Puno, Cuzco, Ayacucho, and Trujillo. Only that of Lima, which is the oldest in America, having been founded in 1551, is of consequence. Its faculties are full, and it is attended by a large number of students. Colombia has a university at Bogotá, and several inferior institutions in provincial cities. The university of Venezuela is at Carácas; it had full faculties and 19 professors in 1874. Of the Central American states, Costa Rica has a university at San José, and Nicaragua two universities, one at Leon and one at Granada. In 1874 San Salvador voted to establish a new university at San Miguel; and in 1875 the university of Guatemala, in the city of Guatemala, was reorganized on the French plan. Mexico has now no university.—In the following table the statistics of the German, Austrian, and Swiss universities are for 1874–'5, of the Italian for 1873, and of the others for years ranging from 1871 to 1875:

UNTERWALDEN, a central canton of Switzerland, bounded N. by Lucerne and Schwytz, E. by Uri, S. by Bern, and W. by Lucerne; area, 295 sq. m.; pop. in 1870, 26,116, of whom 25,687 were Roman Catholics. It is divided into Upper and Lower Unterwalden, the capital of the former, which is the western division, being Sarnen, and that of the latter Stanz. Much of the surface is covered by mountains, which traverse the canton in different directions, and in the south attain a height of upward of 10,000 ft. above the sea. The remainder consists of four principal valleys, which have a general slope toward Lake Lucerne on the N. frontier, into which the chief rivers, the Melch and the Aa, discharge nearly all the drainage of the canton. There are several small lakes, and about one fourth of the area of Lake Lucerne belongs to Unterwalden. The geological formation is chalk, and the canton is remarkable for a great number of caverns. Little of the land is level enough for agriculture, but the pastures are excellent, and cattle constitute the chief wealth of the inhabitants. There are extensive forests. Apples, pears, and chestnuts are raised in great quantities. German is the language of the canton. The government is democratic, and every male inhabitant of 20 years and upward is entitled to vote. Unterwalden was one of the three original cantons of the Swiss confederation.

UPAS TREE, a Javan tree belonging to the breadfruit family (*artocarpeæ*), which botanists now unite with the mulberry family (*moreæ*). The native name of the tree is *bohun upas*, and its resinous and highly poisonous exudation is called *antiar*, a name used for the genus, *antiaris;* while this species (*A. toxicaria*) is poisonous, others are innocuous. The tree reaches 100 ft. or more in height, with a straight trunk and a handsome rounded head; the oblong or ovate leaves, 3 to 5 in. long, are much veined and downy; the monœcious flowers are small and inconspicuous, the pistillate being succeeded by an oval, purple drupe, in appearance like a small elongated plum. When the tree was first made known extraordinary stories were told about it on the authority of Foersch, a surgeon in the service of the Dutch East India company near the close of the 18th century; he represented that the emanations of the upas tree killed all animals that approached it, even birds that flew too near it falling dead; that criminals condemned to death were allowed as an alternative to go to that tree and collect some of the poison, only two out of 20 ever returning; and that he had learned from those fortunate enough to return that the tree was in a valley, with no other tree or plant within 10 or 12 m. of it, all being a barren waste, strewn with human and other bones; he also said that out of a population of 1,600, who were forced by a civil war to take refuge within 12 or 14 m. of the tree, only 300 were alive at the end of three months. These stories were accepted until they were disproved by Leschenault, whose memoir (*Annales du muséum d'histoire naturelle*, 1810) is translated in Hooker's "Companion to the Botanical Magazine," vol. i. So far from growing in a solitary desert, the upas is found in the forests with other trees, and lizards and other animals do not avoid it; its poisonous emanations appear to have a similar effect to those of our poison ivy and sumach, and to affect some persons and not others; several botanists have since collected specimens without unpleasant results, and living plants of upas are now in the principal botanic gardens of Europe, where they are not known to be harmful. It is supposed that the story of the valley of death had its origin in the fact that there was some locality in a volcanic country where an abundant emission of carbonic acid gas produced the fatal results ascribed to the upas tree. The poison has long been used by the natives upon their arrows and other implements of war and the chase; the basis of the poison is the juice of the tree, collected by making incisions, and with this they mix, as do the South Americans in preparing *woorara*, various other substances, which seem to be more required by tradition than for any efficacy they can add to the poison; among those mixed with the upas are the juice of the onion and garlic, cardamom, black pepper, and seeds of a capsicum. When introduced into the circulation of an animal, it acts upon the vascular system, and causes a congestion of the principal viscera, especially the lungs, and death follows in a few minutes. The natives of the same countries use another and more deadly poison, *tieute*, from a species of *strychnos*, which at once affects the nervous system and causes almost instant death. The inner bark of the upas tree affords a fibre which is spun into cloth and worn by the poorer classes as a substitute for linen; if this accidentally gets wet, it produces an intolerable itching. Another species, *A. saccidora*, of Malabar, has a bark so tough that bags for rice and other articles are made from it; the branches are cut into truncheons of the proper size, and the bark removed in such a manner as to leave a thin section of wood as a bottom to the bag.

Upas Tree (Antiaris toxicaria).

UPHAM, Charles Wentworth, an American author, born in St. John, New Brunswick, May 4, 1802, died in Salem, Mass., June 14, 1875. He graduated at Harvard college in 1821, and at the Cambridge divinity school in 1824, and was pastor of the first Unitarian church in Salem till December, 1844, when he left the ministry. He was mayor of Salem in 1852, member of congress in 1853–'5, for several years a member of the legislature, and in 1857-'8 president of the state senate. He edited the "Christian Register" in 1845–'6, and published "Letters on the Logos" (Boston, 1828); "Lectures on Witchcraft, comprising a History of the Salem Delusion, 1692" (1831; enlarged ed., 2 vols. 8vo, 1867); "Life of Sir Henry Vane" (in Sparks's "American Biography," 1835); "Prophecy as an Evidence of Christianity" (1835); "Life of J. C. Fremont" (1856); "Memoir of Francis Peabody" (1869); "Salem Witchcraft and Cotton Mather, a Reply" (1870); and vols. ii., iii., and iv. of the "Life of Timothy Pickering," begun by Octavius Pickering (1867–'72).

UPHAM, Thomas Cogswell, an American author, born in Deerfield, N. H., Jan. 30, 1799, died in New York, April 2, 1872. He graduated at Dartmouth college in 1818, and at Andover theological seminary in 1821, when he became assistant teacher of the Hebrew language. While thus engaged he prepared a translation of Jahn's "Biblical Archæology," which passed through numerous editions. In 1823 he was ordained colleague pastor of the Congregational church in Rochester, N. H.; and from 1825 to 1867 he was professor of mental and moral philosophy in Bowdoin college. Among his works are: "Ratio Disciplinæ, or the Constitution of Congregational Churches" (Portland, 1829); "Elements of Mental Philosophy" (2 vols. 12mo, 1839; abridged ed., 1864); and "Philosophical and Practical Treatise on the Will" (12mo, New York, 1850). He also wrote a series of treatises and memoirs on religious experience, approximating in sentiment to the writings of Tauler, Gerson, and other mystics of the 14th, 15th, and 16th centuries. Their titles are:

"Principles of the Interior or Hidden Life" (12mo, New York, 1848); "Life of Faith" (1848); "Treatise on Divine Union" (Boston, 1851); "Religious Maxims" (Philadelphia, 1854); "Life of Madame Catharine Adorna" (Boston, 1856); "Life and Religious Opinions of Madame Guyon, together with some Account of the Personal History and Religious Experience of Archbishop Fénelon" (2 vols. 12mo, New York, 1847); and "A Method of Prayer, an Analysis of the Work so entitled by Madame de la Mothe Guyon" (1859). Besides these, he wrote "Manual of Peace" (8vo, New York, 1836); "Outlines of Imperfect and Disordered Mental Action" (18mo, 1840); "American Cottage Life, a Series of Poems" (16mo, Portland, 1852); "Letters, Æsthetic, Social, and Moral, written from Europe, Egypt, and Palestine" (8vo, Philadelphia, 1857; new ed., 1865); and one of the essays on a congress of nations (8vo, Boston, 1840).

UPOLU. See Samoan Islands.

UPSAL, or **Upsala. I.** A län or district of Sweden, in Svealand, bordering on the gulf of Bothnia, Stockholm, Lake Mælar, Westmanland, and Gefleborg; area, 2,015 sq. m.; pop. in 1874, 102,629. The sea coast extends about 20 m., and has several small indentations and the large bay of Löftsa. The surface consists of undulating plains, and there are several lakes; the soil is fertile in the south, and the scenery beautiful, but much of the north is barren and bleak. Iron ore is extensively worked, that of Dannemora being the best. Sufficient grain is raised for local consumption, and cattle are largely exported. **II.** A city, capital of the län, on the Fyris or Sala, near its junction with the Skol, 40 m. N. N. W. of Stockholm; pop. in 1873, 12,138. It is in the largest and most fertile plain of central Sweden, and contains fine new buildings and parks. The archbishop of Upsal is primate of all Sweden. The Gothic cathedral, commenced in the latter part of the 13th century and finished in 1435, is the most celebrated of the country, though not improved by the restorations which it has undergone since the damage inflicted by the great conflagration of 1702. Among its relics are those of St. Eric in a silver shrine, the monument of Gustavus Vasa and John II., and many other tombs and monuments in the various chapels, including that of Linnæus. Trinity church in the Odin Lund park, near the cathedral, is a much older building. In the same locality is an obelisk erected in honor of Gustavus Adolphus for his rich endowment of the university. This institution was founded by Sten Sturé in 1477. In 1875 it had 1,480 students (855 in philosophy, 332 in theology, 151 in medicine, and 142 in law), with 31 professors and 68 other teachers. New university buildings are projected, the foundation stone to be laid on the fourth centennial of its foundation (1877). The university library, dating from 1621, is now in a handsome building adjoining the Carolina park, and contains 150,000 volumes and 8,000 manuscripts, including the *Codex Argenteus* of Ulfilas, the most complete copy in Europe of the old Icelandic Edda, the holy book of the Druses, and a Bible with commentations by Luther and Melanchthon. Connected with the university are large numismatic and mineralogical collections, a botanic garden (near the house of Linnæus) with a museum, and an observatory. Upsal has a gymnasium and other schools, and the Gustavian academy and other learned institutions. The greatest business activity occurs in February, when the ancient annual market is held. There is much railway and steamboat traffic with Stockholm.—About 3 m. N. is the village of Gamla Upsala (Old Upsal), the traditional capital of Odin. No vestiges remain of the temple and the sacred grove devoted to his worship, though there are numerous tumuli, of great archæological interest, and considered among the largest N. of the Alps. New excavations have recently been undertaken. In the vicinity of Upsal is the Mora meadow with the Mora stones, renowned from the practice in ancient times of electing the kings here, lifting them upon a large stone in the centre, and engraving the name of each new king, with the date of his election, on a newly deposited stone.

UPSHUR. I. A N. central county of West Virginia, bounded E. by the Middle fork of the Monongahela river, and intersected by the Buckhannon; area, about 500 sq. m.; pop. in 1870, 8,023, of whom 172 were colored. The surface is rolling and in some parts hilly. The soil of the valleys is good. The chief productions in 1870 were 29,958 bushels of wheat, 6,055 of rye, 108,494 of Indian corn, 21,422 of oats, 11,448 of potatoes, 11,190 lbs. of tobacco, 21,857 of wool, 127,158 of butter, and 7,233 tons of hay. There were 2,039 horses, 2,329 milch cows, 4,561 other cattle, 8,000 sheep, and 3,361 swine. Capital, Buckhannon. **II.** A N. E. county of Texas, bounded S. by Sabine river; area, 945 sq. m.; pop. in 1870, 12,039, of whom 4,867 were colored. The surface is nearly level and well timbered, and the soil fertile. The chief productions in 1870 were 326,681 bushels of Indian corn, 8,053 of oats, 40,806 of sweet potatoes, 51,816 lbs. of butter, 1,129 of wool, and 7,362 bales of cotton. There were 2,703 horses, 4,247 milch cows, 8,516 other cattle, 2,262 sheep, and 23,615 swine. Capital, Gilmer.

UPSON, a W. county of Georgia, bounded S. W. by Flint river; area, 384 sq. m.; pop. in 1870, 9,430, of whom 4,565 were colored. The surface is hilly and the soil generally fertile. The Upson County railroad terminates at the county seat. The chief productions in 1870 were 26,594 bushels of wheat, 168,164 of Indian corn, 9,166 of oats, 17,186 of sweet potatoes, 22,695 lbs. of butter, 5,188 of wool, and 4,835 bales of cotton. There were 510 horses, 1,047 mules and asses, 1,238 milch cows, 2,641 other cattle, 1,193 sheep, and 7,558 swine; 2 manufactories of cotton goods, and 1 of cotton yarn. Capital, Thomaston.

URAL, formerly **Yaik,** a river of Russia, forming a part of the geographical boundary between Europe and Asia. It takes its rise in the district of Troitzk, in the Asiatic portion of the government of Orenburg, in the S. part of the Ural mountains. Its source is about 1,600 ft. above the sea, and it flows at first S. past Upper Uralsk, Magnitnaya, and Kizilskaya, bends W. near Orsk, passes Orenburg, and turning S. E. flows past Uralsk, thence S., and discharges into the Caspian sea by several mouths, near Guriev, about lat. 47° N. Its length is estimated at about 1,100 m. Its principal affluents are: on the right, the Kizil, Tanalyk, and Sakmara; on the left, the Or and Ilek. In its upper portion it is obstructed by rapids, and flows through a mountainous country; lower down it passes through wide steppes or saline plains, one of which lying between this river and the Volga is called the Uralian steppe. Toward winter the river near its mouth abounds with fish. The navigation of the Ural is of very little importance. A line of forts has been erected along its shores as a defence against the Bashkirs and Kirghiz.

URAL MOUNTAINS, the chain of mountains forming the N. E. boundary of Europe, and geographically separating European Russia from Siberia, though almost all included in the administrative divisions of the former. Of very moderate height and breadth, the chain would appear insignificant but for the contrast it presents to the great regions of plains that spread from its W. flank over central Russia and from its E. side into Siberia. Its course is nearly due N. and S. over an extent, as usually estimated, of 18 or 19 degrees of latitude, with a general breadth of about 40 m. On the south it begins on the right bank of the Ural river at the Kirghiz steppe, in about lat. 51° N.; but high lands may be traced still further S. into the region lying between the lake of Aral and the Caspian sea. On the north its termination is at the gulf of Kara in the Arctic ocean, though its continuation is marked in the rocky hills on the W. side of Nova Zembla. The highest summit of this portion of the range, named Glassovskoi, is about 2,500 ft. above the sea. The average elevation of the Ural mountains is probably less than 2,000 ft. above the sea, and its highest summits do not reach 6,000 ft. Much of the range blends so gradually into the plains at its sides that it has little of the mountainous character, and is crossed by easy roads, as that by which Yekaterinburg is reached from Perm. The highest summit is Telposis, 5,537 ft.; other principal summits are Deneshkin Kamen, 5,357 ft., and Iremel, 5,038 ft. It is only in the extreme northern part that the mountains remain covered with snow during summer. In general, the chain is clothed with forests of the gigantic *pinus cembra*, above which are often picturesque ledges, frequently overgrown with pæonies, roses, and geraniums. The rocks of which these mountains are composed resemble those of the Appalachian mountains. The lower groups are Silurian strata metamorphosed into crystalline rocks, which for the most part are talcose schists, quartzites, and limestones. To these succeed the upper Silurian, Devonian, and carboniferous, the strata of which are also more or less altered, though still retaining traces of their characteristic fossils. A marked contrast is observed in the appearance of these rocks on the European and Asiatic slopes. On the former the strata are indeed contorted, fractured, and partially changed; while in the centre, as on the eastern slopes, the masses consist everywhere either of highly altered and crystalline Silurian strata, or of the eruptive rocks which penetrate them. It is in these formations, especially where the talcose and chloritic schists are traversed by veinstones of quartz or cut by dikes of igneous rocks, that gold is found. In the debris from these are situated the gold washings, which furnish the chief portion of this metal and of platinum to the Russian government. There are also important mines of iron and copper; and diamonds, emeralds, and various other precious stones are found in the same region. The most important mines are in the neighborhoods of Nizhni Tagilsk, Yekaterinburg, Berezov, Zlatoust, and Miyask.—See *Russlands Montan-Industrie, insbesondere dessen Eisenwesen, beleuchtet nach der Industrie-Ausstellung zu St. Petersburg und einer Bereisung der vorzüglichsten Hüttenwerke des Urals im Jahre* 1870, by P. von Tunner (Leipsic, 1871).

URANIA, one of the nine muses, daughter of Zeus by Mnemosyne. She was regarded as the muse of astronomy, and was usually represented with a little staff pointing at a celestial globe. Urania, "the celestial," was also an epithet of Aphrodite or Venus, as the goddess of pure love, in distinction from Pandemos.

URANIUM, a metal, the protoxide of which, supposed to be the metal itself, was discovered in 1789 by Klaproth in the mineral pitchblende, and was named by him after the planet Uranus, then lately discovered. The metal itself was not really separated until M. Péligot obtained it about 1840 by decomposing its chloride by means of potassium or sodium. Thus produced, it is partly in the form of a black powder, and in part composed of silvery laminæ which can be filed and are somewhat ductile. The metal dissolves in dilute acids, setting free hydrogen gas. Its specific gravity is 18·4. In the air it undergoes no change at common temperatures; but when the metal in the form of a powder is moderately heated, it takes fire and burns with a remarkably white and shining light. The product of this combustion is a deep green oxide. Uranium is represented by the symbol U, and its chemical equivalent is 240 (formerly 60, then 120). It forms two classes of compounds: the uranous, in which it is quadrivalent, as uranous oxide, UO_2 (oxygen being bivalent), and uranous chloride, UCl_4; and the uranic, in which it is sexvalent, as uranic oxide, UO_3, and uranic oxychloride, UO_2Cl_2. Prof. Roscoe in 1875 described a pentachloride, UCl_5. There is also a uranoso-uranic oxide, UO_2, $2UO_3$, or U_3O_8. Uranic oxide unites with basic metallic oxides, forming uranates; and there are salts of the metal uranium with iodine, bromine, and fluorine. The compounds of uranium are employed chiefly in giving yellowish hues to glass and porcelain. The peculiar yellow tint with greenish or opaline reflections seen in Bohemian glass is derived from them. Uranium glass is remarkable for exhibiting with great distinctness the phenomenon of fluorescence, and this property, together with the absorption spectra afforded by uranium salts, has been recently thoroughly investigated by President Morton of the Stevens institute, Hoboken, and Dr. H. Carrington Bolton of Columbia college, New York. (See "The American Chemist," 1873.) Uranium compounds are of great value in porcelain painting, mineral pitchblende being used to a considerable extent at Joachimsthal in Bohemia, where it is converted into uranate of soda for this purpose. It produces an orange color in the enamelling fire, and a fine black in the furnace in which the porcelain is baked. The uranate of soda is of fine orange color, and has been proposed as a paint. Uranium is found accompanying various ores of silver and lead in several of the mining districts of Bohemia, Hungary, and Saxony. It also occurs as a sulphate and carbonate. Torbernite, occurring in beautiful green crystals, is a phosphate of uranium and copper; autunite, found in yellow scales, contains phosphate of uranium and lime. Uranic arsenates of similar composition have been recently discovered. Fine specimens of uranium minerals are found near Redruth in Cornwall, and in various localities in Bohemia and Saxony.—See "Index to the Literature of Uranium," by H. Carrington Bolton, in the "Annals of the Lyceum of Natural History," New York, 1870.

URANUS, or **Cœlus** (Gr. and Lat., heaven), in classical mythology, sometimes the son and sometimes the husband of Gæa or Terra. He preceded Saturn and Jupiter on the throne of heaven. By Gæa he was the father of Oceanus, Saturn, Tethys, Themis, Mnemosyne, the Cyclops, and others. He hated his children, and immediately after their birth confined them in Tartarus; but one of them, Saturn, at the instigation of Gæa, mutilated and dethroned him. From the drops of his blood sprang the Gigantes, and from the foam gathering around him in the sea, according to some accounts, Aphrodite or Venus.

URANUS, the seventh planet in order of distance from the sun, and the outermost but one of all the known members of the planetary system. Uranus travels at a mean distance of 1,753,869,000 m. from the sun, his greatest distance being 1,835,561,000 m., his least 1,672,177,000 m. Hence it will be perceived that the eccentricity of his orbit is considerable, the greatest exceeding the least distance by 163,384,000 m., or by a greater distance than that which separates Venus from the earth when these two planets are furthest from each other. The eccentricity of Uranus's orbit is in fact 0·046578. As a consequence of this eccentricity, his apparent brightness in different oppositions varies considerably. It is not merely that his distance from the earth varies, but his distance from the sun varies also, and consequently the amount of light he receives from it. When at opposition near to the perihelion of his orbit his distance from the earth amounts to 1,581,700,000 m., and when in opposition near aphelion it amounts to 1,744,100,000 m. As his apparent size varies inversely as the square of the distance from the earth, while his apparent intrinsic brightness varies as the square of the distance from the sun, it follows that his apparent absolute brightness is greater when he is at opposition near perihelion than when he is at opposition near aphelion in the proportion of $(17{,}441)^2 \times (1{,}835{,}561)^2$ to $(15{,}817)^2 \times (1{,}672{,}177)^2$, or as 14,651 to 10,000; that is, nearly as 3 to 2. His orbit is only inclined $46\frac{1}{2}'$ to the ecliptic. His mean diameter is about 33,000 m., the compression of his globe unknown. In volume he exceeds the earth about 74 times; but his density being barely $\frac{17}{100}$ of hers, his mass exceeds the earth's only about 12½ times. Some astronomers assert that marks can be recognized on the surface of Uranus, and that by noting these his rotation period can be determined; but very little reliance can be placed on the assigned period of 9½ hours. The sidereal revolution of Uranus is accomplished in 84 years 6½ days, or 30,686·8208 days; his mean synodical period is 369·5 days, or only 4¼ days more than a tropical year.—Uranus was discovered by Sir W. Herschel on March 13, 1781, when he was examining the constellation Gemini (near η) for double stars. Observing that a star in the telescopic field looked larger than the rest, he suspected it to be a comet. Using higher powers, he found the disk enlarged, which would not happen with a star. He thereupon announced the discovery of a comet. But after a short time it was found that the supposed comet was travelling on a nearly circular orbit around the sun; and it was presently recognized as a member of the sun's family of planets. Herschel called it the Georgium Sidus, and foreign astronomers called it Herschel; but the name Uranus, assigned to it by Bode of Berlin, is now always used. In 1787 Herschel discovered two satellites attending on Uranus, and he afterward supposed he had discovered four others; but there is every reason to believe that he had mistaken in most cases small stars for satellites. It appears probable, however, from an inquiry recently instituted by Prof. Holden of Washington, that among his scattered observations of supposed satellites are some really relating to the two inner satellites discovered later by Lassell. The following are the elements of these bodies according to Mr. Hind, superintendent of the English "Nautical Almanac:"

No.	NAME.	DISCOVERED BY	Mean distance in radii of ♅.	Sidereal period.	Longitude of ☊.	Inclination.
1	Ariel	Lassell	7·44	2d 12h 28m	....	....
2	Umbriel	Lassell	10·37	4 3 27	....	....
3	Titania	W. Herschel	17·01	8 16 55	165° 25′	100° 34′
4	Oberon	W. Herschel	22·75	13 11 6	165 28	100 34

It will be observed that the inclination here assigned is greater than a right angle. What is meant is, that the satellites travel on retrograde paths at an inclination of 79° 26′, the complement of that here assigned. It was found, soon after the discovery of Uranus, that the planet had often been observed as a supposed star by Flamsteed, Bradley, Lemonnier, and Mayer. Lemonnier indeed had observed it 12 times. For the interesting result of these researches see NEPTUNE.—The spectroscope has revealed nothing very satisfactory respecting Uranus, though Huggins suspects the presence of large quantities of hydrogen in the planet's atmosphere.

URBAN, the name of eight popes, of whom the following are the most important. **I. Urban II.** (OTHON DE LAGNY), born at Châtillon-sur-Marne, France, about 1042, died in Rome, July 29, 1099. He was archdeacon of Rheims, and became successively a Benedictine monk, prior of Cluny, cardinal, and bishop of Ostia. He was employed by Pope Gregory VII. in the most important missions, and was elected pope at Terracina in 1088, while Rome was held by the antipope Clement III. He was recognized by all Latin Christendom except Germany, where the emperor Henry IV. with a majority of the bishops sustained the antipope, and England, where William II. remained neutral for some time. In 1089 the Romans, having expelled the antipope, put Urban in possession of his see. He immediately summoned a council, excommunicated Clement, Henry, and their adherents, and concluded a matrimonial union between the celebrated countess Matilda of Tuscany and Guelf, son of the duke of Bavaria. The emperor Henry, incensed thereat, marched to Rome with an army in 1091, restored the antipope, and forced Urban to fly for protection to Robert, count of Apulia. In 1093 Conrad, Henry's eldest son, was prevailed upon by Matilda to side with the pope, who crowned him king at Monza. This alliance enabled Urban to regain possession of Rome, excepting the Lateran and the castle of Sant' Angelo. In March, 1095, he held a council at Piacenza, at which 200 bishops, 3,000 of the inferior clergy, and 30,000 laymen were present, and there received the ambassadors of the Greek emperor Alexius Comnenus, who besought his aid against the Turks. There also Urban first appealed to the Christian princes to unite against the infidels, and this led to the holding of the council of Clermont in Auvergne, Nov. 18. In that assemblage Urban proclaimed the first crusade, giving the cross to multitudes amid the shouts of *Dieu le veult!* and ratified the sentence of excommunication pronounced in 1094 by the council of Autun against King Philip I. of France. In the 12 councils held by him Urban labored to consolidate and perfect the reforms of Gregory VII., and condemned the opinions of Berengarius on the eucharist, and those of Scotus Erigena. At the council of Bari, in 1098, he made a fruitless attempt to effect a union of the Greek and Latin churches. Urban was one of the most influential popes of the middle ages. He declared the election of a pope independent of the assent of the Roman emperor, vigorously enforced the law of celibacy, and forbade bishops and priests to accept ecclesiastical offices from the hands of laymen. **II. Urban V.** (GUILLAUME DE GRIMOARD), born at Grisac, Languedoc, in 1309, died in Avignon, Dec. 19, 1370. He was a Benedictine monk, abbot of Auxerre in 1353 and of Marseilles in 1358, and papal legate in Naples and Sicily, and was elected in 1362, at Avignon, successor of Innocent VI. He went in 1367 to Rome, but in 1370 returned to Avignon. In 1369 the Greek emperor John Palæologus himself visited Rome, abjured the peculiar tenets of the Greek church, and acknowledged the supremacy of the pope. In 1370 Urban sent missionaries to the Tartars and an embassy to Georgia, as the churches of Georgia had joined the Greek church. He was the first pope who blessed a golden rose for princes, presenting it to the queen of Naples. He was a liberal protector of letters, and was praised by his contemporaries as entirely free from nepotism. **III. Urban VI.** (BARTOLOMMEO BUTILLI-PRIGNANO), born in Naples in 1318, died in Rome, Oct. 15, 1389. Before his accession to the papal see he was archbishop of Bari. He was elected successor of Gregory XI. in 1378 by the cardinals assembled at Rome; but the cardinals who were residents of Avignon did not recognize him, and in union with some of the Roman cardinals, who declared his election compulsory, elected Count Robert of Geneva pope under the name of Clement VII. (See CLEMENT VII., antipope, vol. iv., p. 661.) Thus began what is known as the great schism in the Roman Catholic church. When Queen Joanna of Naples, who had supported Urban with an army, abandoned his cause, the pope deposed her and anointed in her stead Charles of Durazzo. With him also Urban soon quarrelled. Charles at his coronation in Rome confirmed Francesco Prignano, the pope's nephew, in possession of several Neapolitan provinces bestowed upon him by Urban; but on his arrival in Naples he refused to dismember his kingdom. Urban, having gone to Naples, was there held prisoner for a time by the king; and having moreover alienated the king of Aragon, Pedro, he found himself abandoned by the cardinals. Six of them, at the instigation of Francesco Prignano, being accused of conspiracy, were cruelly tortured and all put to death, with the exception of Cardinal Eston, an Englishman. Urban was besieged by Charles in Nocera, and fled in 1385 to Genoa and Lucca, but in 1388 returned to Rome. He ordered the year of jubilee to be celebrated every 33 years, instead of every 50 as before, and appointed the first for the year 1390.

IV. Urban VIII. (Maffeo Barberini), born in Florence in 1568, died in Rome, July 29, 1644. Under the pontificate of Gregory XIV. he was governor of Fano, and under Clement VIII. papal prothonotary; in 1604 he was appointed archbishop of Nazareth *in partibus infidelium* and ambassador to Paris, in 1605 cardinal, and in 1608 archbishop of Spoleto. He was elected pope, Aug. 6, 1623. He was a patron of sciences and arts, but left the government mostly to his relatives, who favored France and monopolized the most important offices. Through one of his relatives he was involved in a war with the duke of Parma in 1642, which he was obliged to conclude by an unfavorable peace. He bestowed upon the cardinals, the three clerical electors of Germany (the archbishops of Mentz, Cologne, and Treves), and the grand master of the knights of Malta the title most eminent (*eminentissimus*), which led to a long controversy with Venice. He condemned the doctrine of Jansenius, and under his pontificate Galileo was tried and condemned by the Roman inquisition. He established the college of the propaganda, issued a revised edition of the Roman breviary, gave to the bull *In Cœna Domini* its present form, and forbade priests the use of snuff in church under pain of excommunication. He left a volume of Italian poetry, including 70 sonnets. From his knowledge of Greek he was called "the Attic bee;" his Latin poems were printed in 1640 (*Maffei Barberini Poemata*, fol., Paris).

URBANA, a city and the county seat of Champaign co., Ohio, at the intersection of the Atlantic and Great Western, the Pennsylvania Central, and the Sandusky, Dayton, and Cincinnati railroads, 40 m. W. N. W. of Columbus, and 76 m. N. N. E. of Cincinnati; pop. in 1850, 2,020; in 1860, 3,429; in 1870, 4,276; in 1875, locally estimated at 7,000. It is situated in the midst of a fertile country, and is handsomely built. The trade is important. The largest manufacturing concern is the United States rolling stock company, which employs from 300 to 500 hands. Other important establishments are a boot and shoe factory, a tannery, an agricultural machine shop, a stove foundery, two carriage factories, three tobacco works, a woollen mill, two broom factories, two wagon factories, three lumber yards and flouring mills, and a hub and spoke factory, together employing 300 hands. There are three national banks, with a capital of $100,000 each, and one life and one fire insurance company. The high school building cost $90,000, and accommodates 400 pupils. The city has five free public schools, a Roman Catholic school, and a public library. Urbana university (Swedenborgian), founded in 1851, in 1874–'5 had 4 instructors and a library of 5,000 volumes. A daily and two weekly newspapers and a monthly periodical are published. There are 12 churches, viz.: Baptist (2), Episcopal, Lutheran, Methodist (3), Presbyterian, Roman Catholic, Swedenborgian, United Presbyterian, and a mission church.

URBINO (anc. *Urbinum Hortense*), a city of Italy, in the Marches, capital of the province of Pesaro ed Urbino, on an isolated hill in the midst of bleak mountains, 20 m. S. W. of Pesaro; pop. of the town proper about 6,000, and of the whole commune 15,000. It is the seat of an archbishop. The old walls impart to the city a feudal aspect. It is celebrated as the birthplace of Raphael, and for many historical, artistic, and literary associations. The cathedral and other churches contain remarkable paintings. The finest public building, still unrivalled in the *cinque cento* style, is the ducal palace, built by Frederick of Montefeltro from the designs of Lauranna. The free university dates from 1671, and in 1875 was attended by 71 students. The city also possesses a lyceum, a gymnasium, a technological institute, and an academy of science. In the 16th century it had celebrated manufactures of earthenware, and in the 18th of firearms, needles, and pins, and the latter are still extensive.—Urbino was of some importance under the Romans. In the 6th century it was taken by Belisarius. Pope Sixtus IV. in 1474 bestowed the title of duke upon the counts of Montefeltro, the local rulers. Francesco Maria della Rovere, a nephew of Pope Julius II., succeeded to the duchy in 1508 as the son-in-law of the last duke of the Montefeltro line. Under this dynasty the court of Urbino rivalled that of Ferrara in magnificence and in the patronage of art and literature; its most illustrious associations were with Raphael and Tasso. In 1631, on the extinction of the house of Rovere, the duchy, then comprising hundreds of palaces and many towns, became one of the immediate possessions of the Papal States; and in 1860 it was incorporated with the dominions of Victor Emanuel. The anniversary of Raphael's birth and death, occurring on the same day, was solemnly celebrated at Urbino April 6, 1873, and the house in which he was born was purchased in 1874 by the Raphael academy, to be fitted up as a museum.

URCHIN FISH. See SEA PORCUPINE.

URE, Andrew, a Scottish chemist, born in Glasgow in 1778, died in London, Jan. 2, 1857. He was educated at the universities of Glasgow and Edinburgh, took the degree of M. D., and in 1806 was appointed professor of chemistry and natural philosophy in the Andersonian institution at Glasgow. On the establishment of the astronomical observatory in Glasgow he was placed in charge of it. In 1813 appeared his "Systematic Table of Materia Medica," with a dissertation on the action of medicines, followed in 1818 by a remarkable paper entitled "New Experimental Researches on some of the leading Doctrines of Caloric." He also published a "Dictionary of Chemistry" (1821), a translation of "Berthollet on Dyeing" (1823), a "System of Geology" (1829), and numerous papers on chemical subjects. In 1830 he removed to London, and in 1834 was appointed analytical chemist to the board of customs. His subsequent works are: "The Philosophy of Manufactures" (1835), "The Cotton Manufacture of Great Britain compared with that of other Countries" (1836), and his "Dictionary of Arts, Manufactures, and Mines" (2 vols. 8vo, 1837–'9), which has passed through several editions in England and the United States (5th English ed., revised and enlarged by Robert Hunt and several contributors, 3 vols., 1858–60; 7th ed., enlarged, with more than 2,100 woodcuts, 3 vols., 1875).

UREA. See URINE.

UREDO (Lat. *urere*, to burn), a genus of fungi, to which were formerly referred those minute plants which, under the names of smut, bunt, and rust, sometimes produce such disastrous effects upon grain and grasses. The later authorities in this department of botany place the fungi so injurious to grain crops in other genera; those causing what is known as grain mildew are placed in *puccinia;* that which injures the grain of wheat, and is known as bunt, is a *Tilletia;* the various smuts are included in *ustilago;* and the species thus left in *uredo* are not found upon crop plants to an injurious extent. For a general account of these and their polymorphism see FUNGI; an illustration of the effects of one most injurious to our agriculture is given under MAIZE; for more popular descriptions, see "Rust, Smut, Mildew, and Mould," by M. C. Cooke (London, 1865), and a more recent work by the same author, edited by the Rev. M. J. Berkeley, "Fungi, their Nature and Uses" ("International Scientific Series," New York, 1875).

URFA, or **Orfah.** See EDESSA, Mesopotamia.

URI, a canton of Switzerland, bounded N. by Schwytz, E. and S. E. by Glarus and Grisons, S. by Ticino, from which it is separated by the St. Gothard mountains, and W. by Valais, Bern, and Unterwalden; area, 415 sq. m.; pop. in 1870, 16,107, almost all Roman Catholics speaking German. It is one of the three original cantons of the Swiss league, and one of the Four Forest Cantons afterward confederated. It is celebrated for sublime scenery. The Galenstock, the highest peak of the St. Gothard group (12,481 ft.), is near the village of Hospenthal in this canton, and the Uri Rothstock (9,600 ft.) is near the Mythenstein, commemorative of Tell, near the bay of Uri, on the S. E. end of Lake Lucerne. The road over the St. Gothard pass runs through Uri and Ticino and crosses the Reuss, the principal river of the former canton, over many bridges, the most stupendous being the Devil's Bridge (see DEVIL'S BRIDGE, and REUSS); and it also passes the Urnerloch tunnel or hole of Uri. The new St. Gothard railway tunnel passes near Airolo. This village, Andermatt, and Hospenthal are the best known localities in the Urseren valley, the finest in Uri, which is 9 m. long, 1 m. broad, and 5,000 ft. above the sea. In the lower part of the valley is the defile of Schöllenen, which was repeatedly contested during the memorable campaign of the allies against Napoleon in 1799. Uri is essentially a pastoral country. It abounds in cattle, sheep, and goats, and produces excellent cheese. Despite the rough climate, nut and other trees flourish in the valleys. The revised constitution of 1850 is purely democratic. The canton forms two districts, that of Uri, formerly part of the see of Constance, and that of Urseren. Capital, Altorf.

URIC ACID. See URINE.

URIM AND THUMMIM (Heb. *urim*, light; *tummim*, truth or perfection), a part of the breast apparel of the high priest among the ancient Hebrews. According to one opinion, they denote the four rows of brilliant precious stones in the breastplate of the high priest, upon each of which was engraved the name of one of the sons of Israel. When an appeal was made to God by the high priest in difficult cases, the divine answer was manifested in some way by means of this breastplate, or, in the opinion of some commentators, by an audible voice speaking to the priest arrayed in full pontificals. According to others, the Urim and Thummim were two images personifying revelation and truth placed between the folds of the breastplate. The first time they are mentioned in the Bible, they are referred to as things already familiar to the Israelites: "And thou shalt put in the breastplate of judgment the Urim and the Thummim." (Exod. xxviii. 30.) It is unknown when this oracular method of consulting God ceased. There is no instance of it in Scripture during the time of the first temple, and it certainly was not practised during that of the second. There is a rabbinical saying that God spoke to his people during the tabernacle by the Urim and Thummim, during the first temple by the prophets, and during the second by the Bath-Kol.

URINE, the excrementitious fluid eliminated by the kidneys, and containing the products of disintegration or physiological waste of the animal system. The physical and chemical characters of urine present a general resemblance in different classes of animals, accompanied by special variations in regard to particular ingredients. In the human subject the urine is a light amber-colored fluid, of a watery consistency, a moderately acid reaction, and an average specific gravity of 1·024. Its average daily quantity is 35 fluid ounces, or 2¼ pints; but this amount varies, within certain limits, according to the quantity of fluid taken with the food and drink, and that lost by perspiration or otherwise. If the amount of drink be unusually abundant, a part at least of the water so taken will pass off by the kidneys, and the urine will be increased in proportion. On the other hand, should the perspiration from any cause be unusually active, less fluid will be discharged by the kidneys, and the amount of urine will be consequently diminished. These variations evidently depend simply upon the fluctuation of the watery ingredients of the urine, while its solid constituents are comparatively unchanged in amount. Accordingly, its physical qualities, particularly its color, specific gravity, and acidity, vary under these circumstances in inverse ratio to its quantity. When the urine is abundant from excess of water, it is paler than usual, its acid reaction less marked, and its specific gravity diminished. When it is lessened in amount from deficiency of water, it is more deeply colored, of a strongly acid reaction, and of a high specific gravity. Variations of this kind occur from day to day, owing to incidental causes, and are strictly within the limits of health; since the solid ingredients of the excretion, representing the products of bodily metamorphosis, are still discharged, in either case, in their due proportion. Similar fluctuations in the density, color, and acidity of the urine take place naturally at various periods of the day; that passed in the latter part of the day, during the night, and on first rising in the morning, being usually of a deep color, decidedly acid, and of a high specific gravity, often as much as 1·028; while that passed during the forenoon and middle of the day is comparatively pale, often neutral or but slightly acid, and of a specific gravity sometimes as low as 1·016 or 1·018. The specific gravity 1·024 represents the average density of all the urine passed during 24 hours in a state of health.—The average constitution of human urine is:

Water	938·00
Urea	30·00
Creatine	1·25
Creatinine	1·50
Urate of soda	1·80
Urate of potassa	
Urate of ammonia	
Biphosphate of soda	12·45
Phosphate of soda	
Phosphate of potassa	
Phosphate of lime	
Phosphate of magnesia	
Chloride of sodium	7·80
Chloride of potassium	
Sulphate of soda	6·90
Sulphate of potassa	
Coloring matter and mucus	·30
Total	1000·00

Of these ingredients urea is the most characteristic and important. It is a nitrogenized crystallizable substance, freely soluble in water, and exists in very minute proportion in the healthy blood of man and mammals generally. It represents one product of the physiological waste or retrograde metamorphosis of the system, though it is not yet certain from what special set of tissues or organs it is derived. It is increased by muscular exertion or by a diet of animal food, and diminished by repose or by a diet consisting of vegetable and non-nitrogenous substances. It is constantly eliminated from the blood by the kidneys, during its circulation through their vessels; and this explains the fact that, although it exists in healthy blood only in the proportion of 0·16 part per thousand, it is found in the urine in the proportion of 30 parts per thousand. It is, in fact, constantly drained away from the blood and accumulated in the urine, to be thus discharged from the body. The average quantity in which urea is produced and discharged in man during health is 500 grains a day. If, from ligature of the renal arteries or disabling affections of the kidney, the urea is retained and allowed to accumulate in the blood, it becomes poisonous as soon as its quantity has increased to a certain point, and signs of disturbance of the nervous system and of nutrition generally come on, and become constantly aggravated until they terminate in death. This happens more particularly in both the acute and chronic form of Bright's disease. (See ALBUMINURIA.) Creatine and creatinine are also both nitrogenous crystallizable substances, products of disintegration. They are produced in the muscular tissue, from which they are absorbed by the blood, and thence in turn eliminated by the kidneys. The urates of soda, potassa, and ammonia are combinations of these bases with a nitrogenous acid body of organic origin, namely, uric acid. Uric acid by itself is extremely insoluble in watery fluids, but its saline combinations with the above named alkaline bases are readily soluble in the proportions of water usually existing in the urine. They may however be decomposed by the addition of a free acid to the urine, or by the development of such an acid in it from the changes of decomposition. The new acid then combines with the alkaline bases, and the insoluble uric acid thus set free is deposited in the crystalline form. It is in this way that "uric acid gravel" is formed in the urine, or that calculi composed of uric acid increase in size. The quantity of urates ordinarily discharged by the urine in health is about 25 grains a day. The acid reaction of the urine is due to the presence of the biphosphate of soda, the solutions of which are acid to test paper. The alkaline phosphates, that is, the phosphate of soda and the phosphate of potassa, are themselves soluble in water. The earthy phosphates, on the other hand, that is, the phosphate of lime and the phosphate of magnesia, require an acid fluid for their solution; consequently they are readily held in solution in the urine so long as it maintains its natural acid reaction. But if it be rendered alkaline by the addition or formation of an alkaline ingredient, it at once becomes turbid by the deposit of the earthy phosphates. These deposits may be easily recognized by their being redissolved on the addition of a small quantity of any mineral or vegetable acid. The chlorides and sulphates of the urine are all readily soluble, and seldom or never appear as a deposit. After being discharged from the bladder, the urine, if kept exposed to the atmosphere at a moderately warm temperature, undergoes decomposition. The minute quantity of animal matter existing in the mucus becomes a ferment, and causes the urea to be gradually transformed into carbonate of ammonia. This first neutralizes the acid reaction of the urine and causes it to become turbid from a deposit of its earthy phosphates. Subsequently, as the products of decomposition increase in quantity, the urine becomes strongly alkaline and saturated with the ammoniacal salt, which forms a new crystalline combination, namely, the phosphate of magnesia and ammonia, or the so-called "triple phosphate," and finally exhales from its surface a strong ammoniacal vapor. This goes on until all the urea originally existing in the urine has been thus decomposed and returned to the atmosphere or the soil under the form of an ammoniacal combination.

URN. See BURIAL.

URQUHART, David, a British author, born at Bracklanwell, county of Cromarty, Scotland, in 1805. He was educated at Oxford, travelled in the East, and in 1835 was appointed secretary of legation at Constantinople. He resigned this office in 1836, returned to England, and charged the Palmerston ministry with Russian tendencies and betrayal of British interests, renewing his attacks from Paris in 1840. He was elected to parliament for Stafford in 1847, but failed of reëlection in 1852. He has published "Observations on European Turkey" (1831); "Turkey and its Resources" (1833); "Spirit of the East" (1838); "Exposition of the Affairs of Central Asia" (1840); "Exposition of the Boundary Differences between Great Britain and the United States" (1840); *La crise, ou la France devant les quatre puissances* (Paris, 1840); "Annexation of Texas a Cause of War between England and the United States" (1844); "The Pillars of Hercules, a Narrative of Travels in Spain and Morocco" (2 vols., 1850); "Progress of Russia" (1853); "Recent Events in the East" (1854); and "The Lebanon" (2 vols., 1860).

URQUIZA, Justo José de. See ARGENTINE REPUBLIC, vol. i., pp. 694–'6.

URSA MAJOR, and **Ursa Minor.** See BEAR, GREAT AND LESSER.

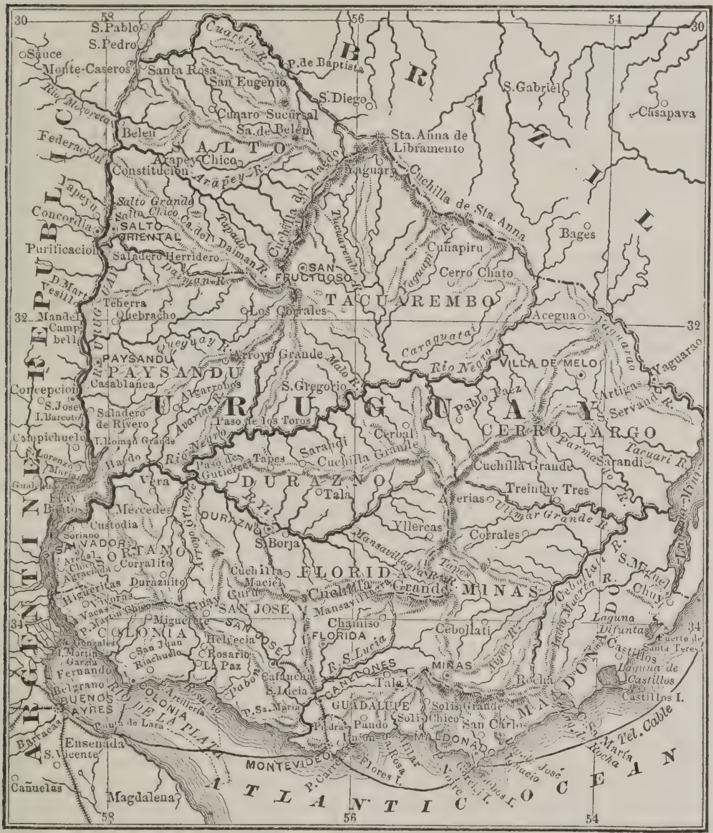
URSULA, a saint of the Roman Catholic church, and, according to the legend, a daughter of a Christian prince of Britain. The date of her martyrdom is variously given as 237, 383, or 451. She was demanded in marriage by a pagan prince, and fearing by a refusal to bring ruin upon her parents and country, she seemingly consented, but obtained a delay of three years, and a grant of 11 triremes and 10 noble companions, each as well as herself attended by 1,000 virgins. She passed the three years with her virgins in nautical exercises; and when the day fixed for her marriage arrived, a sudden wind arose at their prayer, and wafted them to the mouth of the Rhine, and thence to Basel. Here they left their vessels, and made on foot a pilgrimage to Rome. On their return they fell in unexpectedly at Cologne with an army of Huns, by whom they were massacred, Ursula having refused an offer of marriage from the prince. Their corpses were buried by the people of Cologne, and a church was afterward erected in their honor, in which an immense collection of bones is still exhibited as those of Ursula and her companions. The first traces of this legend, which was gradually enlarged, are met with in the 9th century.

URSULINES, a monastic order in the Roman Catholic church, founded at Brescia in 1533 by Angela Merici (born at Desenzano in 1474, died March 21, 1540, canonized May 24, 1807). It was at first a voluntary association of widows and young girls, who undertook the gratuitous education of children of their own sex, devoting their spare hours to visiting the sick and relieving the poor. The members were allowed to live at home, submitting only to such regulations as the nature of their work and other circumstances required. As their numbers increased they formed distinct congregations. In 1541 they assumed for their common dress that worn in the country by widows of the middle class. In 1544 their mode of life was approved by Pope Paul III., and, their establishments becoming numerous in northern Italy, they began to live together in common and to elect local superiors, but without binding themselves even by temporary vows. In 1572, at the instance of St. Charles Borromeo, Pope Gregory XIII. erected the congregation of St. Ursula into a religious order, under the rule of St. Augustine, the members adding to the three ordinary monastic vows a fourth binding them to instruct young girls gratuitously. Several of the local congregations declined to be members of the new order, and with the consent of the church retained their first organization unchanged. Thus, after 1572, the Ursulines were divided into the new or "regular" Ursulines and the "primitive" Ursulines. The first colony established in France was made by Françoise de Bermond at Avignon in 1594, with the special approbation of Pope Clement VIII. In 1608 two members of this establishment went to Paris at the request of Madeleine Lhuillier de Sainte-Beuve, and opened a central house there, which was approved in 1612 by Paul V. Other branches sprang up rapidly around the mother house of Avignon, one of the most fruitful of which was planted at Clermont in Auvergne by Clémence du Ranquet in 1602. The primitive Ursulines also spread beyond the Alps. In 1606 Anne de Saintonge of Dijon formed several establishments of them, which were favored by the bishops and became very popular throughout Franche-Comté, living in strict retirement without being cloistered, binding themselves by permanent vows only after several years of probation, and educating gratuitously the children of the poor. But these only formed a small minority of the French Ursulines, who in 1715 had 11 provinces and upward of 350 monasteries. The first Ursuline colony in America was founded in 1639 at Quebec by Marie Guyart, known as Mère de l'Incarnation, the first processes for whose beatification were begun at Rome by the Canadian bishops in 1869. All the Ursuline convents are under the jurisdiction of the diocesan bishop, and their coherence is so loose that many convents do not even know to which of the numerous congregations they belong. There are Ursuline convents in the United States at Morrisania (New York city), Cleveland, Toledo, and Fayetteville, O., Springfield and Alton, Ill., Columbia, Savannah, and Augusta, Ga., New Orleans, San Antonio, Galveston, Louisville, and St. Louis; and in Canada at Quebec, Trois Rivières, and Chatham. The Ursulines have ceased to exist in Italy, Switzerland, and Germany since 1871.

URUGUAY, or **Banda Oriental del Uruguay,** a republic of South America, lying between lat. 30° and 35° S., and lon. 53° and 58° 30′ W., bounded N., N. E., and E. by Brazil, S. E. and S. by the Atlantic, and S. W. and W. by the Rio de la Plata and the Uruguay, which separate it from the Argentine Republic. Uruguay has a shore line of 200 m. on the Atlantic, 155 m. on the Plata, and 270 m. (in a direct line) on the Uruguay, making 625 m. accessible to shipping; while the land frontier is only 450 m. The sea coast is low, sandy, and devoid of safe harbors; the coast on the Plata is high and rocky, indented by several open bays; and the banks of the Uruguay are generally low, with intervals of moderately high table land. The interior is traversed by chains of wooded hills, from which descend innumerable streams uniting in small rivers, navigable for considerable distances by small craft. Extensive undulating grassy plains (*pampas*) form the chief feature of the country. The Cuchilla Grande is the principal mountain ridge; others are the Carapy, Castellos, and Yerbal. The highest land is the Cerro Pelado in the department of Minas, nowhere exceeding 2,500 ft. above sea level. The Rio Negro rises in the sierra Santa Anna, crosses the republic from N. E. to S. W., dividing it into two nearly equal parts, and after a course of about 350 m. flows into the Uruguay about 80 m. above its junction with the Paraná. Among other rivers are the Dayman, 100 m. long, navigable 18 m.; the Queguay, 150 m. long, navigable 30 m.; the San José and Santa Lucia, respectively 100 and 120 m. long, which unite 12 m. from the estuary of the Plata and are navigable about 25 m.; and the Cebollati, which flows N. E. into Lake Merim in Brazil, receiving numerous tributaries. The climate is mild and healthful. The thermometer ranges from 32° to 88° F.; but on the table lands heavy frosts occur in July and August, and in the low lands the temperature occasionally rises in February above 100° F. An abundance of rain falls in all seasons, but the greatest amount in May and October; snow seldom falls, and rapidly disappears. The temperature occasionally rises 25° in two or three hours, and frequently falls 40° in four hours. The soil is very rich, yielding abundant crops of grain, a great variety of fruits and vegetables, sugar cane, and cotton. Among the trees are the walnut, willow, cedar, myrtle, mulberry, laurel, orange, lemon, olive, fig, pomegranate, apple, pear, almond, peach, plum, cherry, and guava; lignum-vitæ, taruman, and other hard woods; and the quebracho and scarlet willow, which furnish excellent dyes. Among the medicinal plants are the poppy, wormwood, gentian, balsam, coriander, chamomile, liquorice, and sarsaparilla, the last growing in great abundance along the banks of the Rio Negro and its tributaries. Gold, silver, lead, iron, copper, marble, agates, alabaster, and amethysts are found; but the mineral resources are hardly developed, though several mines have lately been opened. Jaguars are sometimes seen along the banks of the Uruguay, and pumas on those of the Rio Negro. The carpincho, deer, ostrich, partridge, duck, parrot, plover, swan, and goose abound. The rivers furnish a variety of excellent fish, and the Plata contains a great many sea wolves. —The republic is divided into 13 departments, which, with their areas, chief towns, and population in 1872, are as follows:

DEPARTMENTS.	Area, sq. m.	Population.	CHIEF TOWNS.	Population.
Cerro Largo.	7,530	33,000	Villa de Melo.........	5,000
Colonia.....	1,900	22,508	Colonia del Sacramento	2,000
Durazno....	4,850	16,281	Durazno..............	1,500
Florida.....	4,100	19,900	Florida...............	2,000
Guadalupe..	1,600	48,000	Canelones............	3,000
Maldonado..	5,150	18,750	Maldonado...........	1,000
Minas......	4,985	27,163	Minas................	1,700
Montevideo.	225	127,704	Montevideo...........	105,000
Paysandú...	7,360	33,052	Paysandú............	9,000
Salto.......	8,125	32,602	Salto.................	10,000
San José....	3.890	20,115	San José............	5,000
Soriano.....	3,125	21,403	San Salvador.........	1,500
Tacuarembo	10,460	34,000	San Fructuoso........	3,000
Total.....	63,300	454,478		

Montevideo is the capital of the republic. Of the population 254,000 are foreigners, including 60,000 Italians, 30,000 each of Basques, Spaniards, and French, 20,000 Brazilians, 10,000 Argentines, 10,000 English and Germans, 2,000 Portuguese, and 12,000 Africans. The aborigines have entirely disappeared. The bulk of the native population is a mixture of Indian, European, and African blood. The characteristics of the lower classes are ignorance, treachery, and cruelty; their occupation as herdsmen, the frequency of civil wars, and the general prejudice against education have prevented the progress of civilization. (See Gaucho.) The language of the country is Spanish.—The number of persons engaged in agricultural pursuits is rapidly increasing. The annual value of wheat and maize alone is more than $3,000,000. In 1874 the mills of Montevideo turned out 62,000,000 lbs. of flour. But the main wealth of the country is in its pasturage. In 1874 the country had 7,254,000 cattle, 1,463,000 horses, and 18,476,000 sheep. The wool, which is of superior quality, is almost wholly exported. The manufactures are confined to a few coarse articles for home use. In 1874 the exports were officially given at $15,240,000, and the imports at $16,320,000. With the addition of contraband shipments to avoid the oppressive export duties, it is computed that the total value of the exports would be not less than $25,000,000. The chief articles exported are hides, wool, skins, tallow, and jerked beef. The imports comprise all kinds of manufactured articles, provisions, and coal. Most of the trade is with Great Britain and France, which together take half the exports; Brazil comes next, and the United States next, taking in 1874 articles to the value of $3,254,000. While the trade with other countries is decreasing, with the United States it is gradually increasing. The arrivals in 1874 were 1,888 vessels, of 986,827 tons; cleared, 1,821 vessels, of 954,712 tons. The mercantile tonnage of the country is almost entirely in small coasters and river steamers. European steamers arrive and depart almost daily. There are 176 m. of railway in operation, about 200 m. in course of construction, and 500 m. in contemplation. The telegraph lines in operation aggregate 1,300 m. There is telegraph connection with Europe and North America by way of Rio de Janeiro, and also by way of Buenos Ayres and Chili.—The form of government is in theory republican, similar to that of the United States, but in practice it is a military despotism alternating with anarchy. The constitution provides for the equal rights of all men, prohibits slavery, guarantees freedom of the press and liberty of conscience, and to foreign residents the same rights as natives, with exemption from military service. The president is elected for four years, but may not be reëlected until after a lapse of four years. He appoints four ministers, viz., of the interior, foreign affairs, finance, and war. The legislature consists of a senate of 13 senators, one from each department, elected for six years and presided over by a vice president elected for four years, and a house of deputies of 40 members elected for three years. It is in session from Feb. 1 to June 15, but a committee of two senators and five deputies sits during the year. The courts comprise a supreme tribunal of five judges, two criminal courts, two civil judges, a tribunal of commerce, and several district judges for hearing petty cases. The ecclesiastical authorities are a bishop and provisor general of the Roman Catholic church. The municipal boards or juntas have control of the



public schools, markets, and roads. The revenue for 1874 was $6,375,000; the expenditures were $8,500,000. Of the former seven-eighths is derived from customs, nearly half of which is set apart to pay interest on and provide a sinking fund for the public debts. The revenue for 1875 was estimated at $7,442,000, and the expenditures at $6,775,738. There was a falling off of $813,600 in the customs receipts during 1874. On Jan. 1, 1875, the public debt was $42,357,695. In 1875 the army consisted of 573 officers and 2,797 men, the national guard numbering 20,000. The navy consists of one gunboat of four guns and three tugs of one gun each. There were 245 schools, of which 134 were private, with an average attendance of 16,786 pupils. There were 26 newspapers, with a daily aggregate circulation of 18,000 copies. The churches number 47 Roman Catholic and 3 Protestant. There are four convents, one university, one public library containing 10,000 volumes, several charitable institutions, eight lighthouses, and three dry docks, two in Montevideo and one in Colonia. Of the four banks formerly existing in Montevideo, one failed in 1875, and it was proposed to fuse the other three in a national bank. The decimal and metric systems of values, weights, and measures have been in use since 1864. The *peso* of 100 *centavos* is equal to $1 05 American coin.—The first permanent settlement of the territory was by Jesuit missionaries on the Uruguay in 1622. Subsequently other Spanish colonies were established. The Portuguese, desirous of extending the southern boundary of Brazil to the Plata, also established colonies, notably that of Colonia in 1680, and soon afterward another on the present site of Montevideo. These two nations were engaged in a continuous struggle for possession till 1724, when the Spanish were victorious, and in 1776 the territory was included in the viceroyalty of Buenos Ayres as the district of Banda Oriental. When the war for independence began in 1811 the Banda Oriental at first sided with Buenos Ayres, but in 1814, Montevideo having been rescued from the Portuguese, who had invaded the country, it fell under the power of José Artigas. (See Artigas.) The Portuguese again invaded the country in 1816, and, after the fall of Artigas, in 1821 forced the legislature to decree annexation to Brazil. When Brazil became an independent empire the Banda Oriental was included as a Brazilian province under the title of Cisplatina. In 1825 a revolution broke out, and the independence of the country was declared, which in 1828 was recognized, the N. part, known as the Seven Missions, being ceded to Brazil, and the remainder becoming an independent state entitled Republica del Uruguay Oriental. Internal dissensions began soon after the adoption of the constitution in 1830. Two parties, known as the reds and the whites, terribly distracted the republic. In 1839 one of the unsuccessful candidates for president, Oribe, head of the whites, aided by Rosas, the dictator of Buenos Ayres, raised an army, invaded the country, and subsequently laid siege to Montevideo. This siege lasted nine years, and the war reduced the state to the verge of ruin. England and France interfered and compelled the combatants to lay down their arms. The overthrow of Rosas resulted in the restoration of peace in 1852, which lasted till 1860, when Flores, an ex-president, invaded the country and provoked a civil war. He was defeated at Las Piedras, Aug. 16, 1863. In 1864 war broke out between Uruguay and Brazil. Aided by the Brazilian army, Flores entered Montevideo, Feb. 23, 1865, became provisional president, and renewed the treaties with Brazil. On May 1 the Argentine Republic, Brazil, and Uruguay made a treaty of alliance against Paraguay, and on Aug. 17 the allies under Gen. Flores defeated the Paraguayans. (See Paraguay.) In 1866 Vidal was elected president of Uruguay. On Feb. 19, 1868, during an insurrection at Montevideo, Flores was assassinated. In March, 1868, Gen. Lorenzo Battle became president. Another revolution broke out in 1870 and continued without decisive results till 1873, when José Ellauri was elected president. He was subsequently deposed by his own party, the reds, and succeeded in 1875 by Pedro Varela, who in his turn was forced to resign in March, 1876, Señor Latorre assuming the dictatorship.

URUGUAY, a river of South America, which rises on the W. slope of the Serra do Mar in the Brazilian province of Santa Catharina. During the first 75 m. of its course it flows N. W. through the plains of Las Vacas, where it unites with the Pelotas and is increased by numerous small tributary streams. It is subsequently joined by the Pepiri-Guassú, and turns S., forming the boundary between the Brazilian province of São Pedro and the Argentine provinces of Corrientes and Entre-Rios, from all of which it receives many additions. At its junction with the Ibicuy, which rises in the Sierra Geral, it is 600 yards wide. In lat. 30° 14′ S. it receives the Quaraim, an important tributary, 160 m. long, and navigable for 30 m., which marks the boundary between Brazil and Uruguay. The Uruguay is here 1,500 yards wide, and divided by a line of wooded islands. Thence to its mouth it is the boundary between the Argentine Republic and Uruguay. The western shore is high, steep, and wooded, the eastern very varied and picturesque. The next important tributary is the Arapey from the east; here the bed becomes rocky and the current more rapid, until it forms the cataract of Salto Grande, which is about 250 m. above its junction with the Paraná. This is frequently passed by steamers during high floods, and above it there is unimpeded navigation for vessels drawing 5 ft. for a distance of 300 m. Below it the river is rapidly augmented by numerous tributaries, until in the lower part of its course, for nearly 100 m., it becomes a lake, varying in width from 4 to 7 m. The right bank is here low, wooded, and often marshy; the left is formed by the slopes of hills 200 to 500 ft. high, intersected by numerous streams and interspersed with settlements. In lat. 34° it unites with the Paraná to form the Plata. The Rio Negro is its largest affluent. The total length of the Uruguay is 1,020 m. Its waters are always clear and limpid. Its islands, much less numerous than in the Paraná, are mostly high and rocky. On the island of Higuerita is a populous town. On its banks are the Uruguayan towns of Fray Bentos, Paysandú, and Salto, the Argentine towns of Concepcion and Porto Ruiz, the port of Gualeguaychú, and the Brazilian towns of Uruguayana and Itaqui. The main stream is navigable about 600 m. for flat-bottomed steamers and 200 m. more for boats. The annual freshets occur in September or October, sometimes with great rapidity. The average rise is 20 ft., but occasionally there is a difference of 40 ft. between extreme high and low water.

URUMIAH, or Oroomiah. **I.** A town of Persia, in the province of Azerbijan, 65 m. S. W. of Tabriz; pop. estimated by the Austrian consul general in 1872 at 50,000 (other estimates varying from 25,000 to 40,000), chiefly Mohammedans, but including several thousand Jews and Nestorians. Embosomed in foliage and orchards, Urumiah is one of the most beautiful towns of Persia, extending over a mile, and having fine open spaces and gardens and several good streets. The jurisdiction of the local authorities extends over 10 districts, with an aggregate population of about 150,000. The Protestant mission here has been transferred from the American board of foreign missions to the Presbyterian board, whose organization in the neighboring village of Seir dates from the end of 1872. It comprises a printing office, which in that year issued 3,230 volumes in the old and new Syriac languages, 3 main and 50 subsidiary stations, 50 native preachers, 95 teachers, 55 schools, a female seminary, and more than 700 church members. In the vicinity of Urumiah are mounds believed to have been used in early periods for the rites of the fire worshippers. Urumiah, under the name of Thabarma, was by the early Persians held sacred as the birthplace of Zoroaster. **II. Lake,** a body of water in the vicinity of the town, forming an oblong and shallow basin, nowhere exceeding 24 ft. in depth, extending in its longer direction from N. N. W. to S. S. E. over 80 m., with an average width of about 25 m. It is 4,200 ft. (according to Rawlinson) above the sea level. Its waters, heavily impregnated with salt, resemble those of the Dead sea; the color is deep blue, whence the Armenian name of Kapotan Zauw, "Blue sea." On the E. side a peninsula projecting far into the lake divides it into unequal northern and southern portions; the latter and larger contains a group of islands, some of which are large. The lake receives many important streams. Among the most interesting towns near the E. shore is Maragha, which once had an immense population, now reduced to about 20,000, after which the lake is called by the Arabs.

URUS. See AUROCHS.

USES. The word *usus* was employed in the Roman civil law, and there meant a right to take so much of the fruit or profit of a thing as was needed for sustenance; while *usufructus* had a larger meaning, including a qualified right of possession. In the law of England and the United States, the word use has a precise meaning, which is similar to that of the *fidei commissum* of the Roman law. It means a confidence reposed in one who has the property (or to whom it is given) in possession, that he will hold it for the use or benefit of another, who is called in Norman French the *cestuy que use.* A Roman magistrate (a prætor) was charged with the enforcement of these *fidei commissa*, and was called *commissarius.* When uses became common in England, the chancellor, under whose jurisdiction they passed, had much the same duty to perform as the Roman *commissarius;* and indeed Lord Bacon calls this magistrate a Roman chancellor.—Uses were invented in England to avoid and defeat the statutes of mortmain (see TRUST); and to protect those statutes against uses, the statute of 27 Henry VIII., commonly called the statute of uses, was enacted. This provided that any person or corporation entitled to a use in fee simple, fee tail, or otherwise, should stand seized and possessed of the land itself, in the like estate which they had in the use; the intention being to subject a conveyance to the use of any one, and the property and the *cestuy que use*, to the same legal restraints and liabilities as if the conveyance had been made directly to the *cestuy que use.* This statute was said, in legal phraseology, "to execute the use." It was intended to prevent conveyances to use, by making them of no effect where they violated the statutes of mortmain, and of no more effect than a direct conveyance where they did not. Still such uses as the law permitted, or as courts of equity could protect, were found to be exceedingly convenient, and became common; and courts of equity retained their hold upon them, the person to whom the conveyance was made being considered as having the legal estate, subject to the rules of law and the jurisdiction of courts of law, while the *cestuy que use* has an equitable estate subject to the rules and the courts of equity. This is now the prevailing condition of the law of uses in England and in the United States. But the whole system of law and of equity in regard to uses has become as intricate and extensive as it is important. Here we can do no more than indicate the principal rules of this system.—There can be no use, unless: 1, there is a person capable in law of taking it; 2, a person capable in law of being seized of the property to the use of the other; 3, an express declaration of use, or a consideration and a transfer or contract from which the court will imply a use; and 4, sufficient estate or property or interest to sustain a use. Then, if a use exists which the courts can recognize, it is descendible, or heritable, or devisable, or transferable according to the rules of law or equity, in conformity with the provisions in the instrument creating the use. If the *cestuy que use* of land be married, his widow has no dower, and the husband of a *cestuy que use* has no tenancy by courtesy, because the *cestuy que use* has no seisin, nor can he bring an action at law respecting it. The seisin is in the feoffee-to-use, and while his legal estate is subject to all legal incidents at law, equity will subject all these legal incidents to the equitable requirements of the use.—Trusts and uses are often spoken of together, and from the article on Trusts their similarity or analogy will be seen. They differ however in important particulars.

USHANT (Fr. *Ouessant*), the chief of seven islands known as *îles d'Ouessant*, belonging to the department of Finistère, about 11 m. from the nearest coast of France, and 25 m. W. N. W. of Brest; extreme length nearly 5 m., breadth 3 m.; pop. about 2,400. The shores are bold and rocky, and the landing places few. The formation is mainly granitic, and the soil is fertile, with excellent meadows and pasture lands, and many horses and sheep are reared. The inhabitants are principally occupied in fishing. The lighthouse is in lat. 48° 28′ N., lon. 5° 3′ W. Off Ushant the British fleet under Sir Edward Hawke gained a victory over the French under Admiral Conflans on Nov. 20, 1759; and there was an indecisive action between the English under Admiral Keppel and the French under Count d'Orvilliers on July 27, 1778.

USHER, James, an Irish prelate, born in Dublin, Jan. 4, 1580, died in Reigate, Surrey, March 21, 1656. He was educated at Trinity college, Dublin, was ordained priest in 1601, and soon after was appointed "Sunday afternoon preacher before the state" in Christ church, Dublin. In 1603 and 1606 he visited England and became acquainted with Sir Thomas Bodley, Sir Robert Cotton, and other distinguished persons; and from this time he often visited the English libraries. In 1607 he was chosen professor of divinity in his college, and became chancellor of the cathedral of St. Patrick. In 1620 King James nominated him to the see of Meath; in 1623 he was made a member of the Irish privy council; and in January, 1624, he was raised to the archbishopric of Armagh and the primacy of the Irish church. While he was visiting England in 1641, his house was destroyed by the rebels, with nearly all he possessed, and he did not return. Charles I. conferred upon him the bishopric of Carlisle, to be held *in commendam.* In 1647 he was chosen preacher to the society of Lincoln's Inn, and served in term time for nearly eight years. He published *Annales Veteris et Novi Testamenti* (2 vols. fol., 1650–'54), in which he set forth the system of sacred chronology which has been largely adopted, and is printed in the margin of the English Bible. He also wrote works on the incarnation, British ecclesiastical antiquities, variations of the Hebrew text, &c. A complete edition of his works has been published by the Dublin university in 17 vols. (1841–'64).

USUMASINTA RIVER. See Guatemala.

USURY. Originally this word meant any taking of money for the use of money; and he was therefore a usurer who, lending money, required in payment anything more than the amount which he lent. This was once considered a great moral wrong, but it is no longer deemed more wrong to take pay for the use of money than for the use of a house, or a horse, or any other property. But the lingering influence of the former opinion, together with the fact that the nature of money makes it easier for the lender to oppress the borrower, has caused nearly all Christian nations to fix by law the rate of compensation for the use of money. If compensation be taken within this limitation of law, it is called interest; but if more be taken than the law allows, this in the present meaning of the word is usury. The opinion that money should be borrowed and repaid, or bought and sold, upon whatever terms the parties should agree to, like any other property, has of late years gained ground almost everywhere; and where usury laws are in force, this opinion has perhaps exerted some influence upon adjudication. In England, in the reign of Henry VIII., interest at 10 per cent. was made lawful; in the time of James I. it was reduced to 8 per cent.; during the commonwealth it was 6 per cent., and this was again enacted by 12 Charles II.; the statute of 12 Anne reduced it to 5 per cent. The act 3 and 4 William IV. exempted from the operation of the usury laws bills having more than three months to run. After several modifications in the reign of Victoria, the act 17 and 18 Victoria, ch. 90, repealed all laws then in force relating to usury, providing only that the rights and remedies of persons in respect to acts previously done should not be affected by the statute.—In the United States, the usury laws differ in different states, and are not perhaps precisely the same in any two. In Louisiana 5 per cent. is the legal rate; in Connecticut, Georgia, Kansas, Michigan, Minnesota, New Jersey, New York, South Carolina, and Wisconsin it is 7; in Alabama, Florida, and Texas it is 8; in California, Nebraska, Nevada, and Oregon it is 10; in all the others it is 6. But the statutes vary exceedingly as to the legal effects of usury. In California, Florida, Maine, Massachusetts, Nevada, South Carolina, and Texas, the parties may agree on what rate they will, and the legal rate takes effect only in the absence of agreement; in New Hampshire, New York, North Carolina, and Tennessee, the whole contract is avoided by a reservation or agreement for more than the legal rate. Regarding these as extremes, in much the greater number the penalty for usury lies between them. In some states the legal rate takes effect when there is no agreement, but the parties may agree for more up to a certain definite limit.—There are many ways in which the usury laws may be evaded, and courts watch contracts liable to this abuse with great strictness. Some principles may be gathered from the adjudications, which may be regarded as prevalent, if not universal. Thus, to constitute usury, there must be substantially a loan, and a usurious intent in both parties, in one to give and in the other to take usurious interest. But the contract need not be, in form, a loan; and whether it is so in fact is a question for a jury. Property may be sold for whatever price the parties agree upon; but if the sale be in fact a mere cover for the usury, it does not protect it. Negotiable paper may be sold like other paper. The cases on this subject are numerous, nice, and perhaps conflicting; but it may be stated as a general rule, that if it is in fact the promissor who sells, and the buyer buys even through an agent, but with knowledge that he buys of the promissor, it is in fact and in law a loan from the buyer, and may therefore be usurious. Even if a statute declares a usurious contract "void" in the most emphatic language, the law looks upon it rather as "voidable;" and therefore no one can make the objection of usury but the borrower and the parties in privity of interest and contract with him. So, if one borrows stock, agreeing to replace it with the dividends received in the mean time, or if he agrees to replace it, or the money it sells for, with interest on its value, the contract is not usurious; but if the lender retains an option to take either the dividends or interest, it is usurious. If a note be given usuriously in payment of or as security for a preëxisting debt, and the note is void by the usury laws, the original debt remains unaffected. As there must be usurious intent, if illegal interest is taken by a miscalculation or other mistake in fact, it is not usury; but it is usury if the mistake be one of law, because every person is held to know the law. If the lender takes upon himself an extra risk (apart from that of the borrower's insolvency), he may charge extra interest. Bottomry and respondentia contracts are founded on this principle, because if the ship or goods are lost, the debt is not demandable. The same principle is applied to the purchase of an annuity, and even to the bargain of the borrower that if he does not repay the principal when due with legal interest, he will pay a certain penalty, because he has the power of avoiding this penalty by payment of interest. If a borrower on repaying the money make the lender a gift, it is usurious if the gift be in performance of a previous promise, but not otherwise. Discount of interest, whereby the lender gets interest on his interest, or interest on money which he never lends, and calculations of interest by Rowlett's tables, which consider the year as consisting of only 360 days (but qualify the error by casting the fractions on the right side), are now established usages, and do not make the contract usurious, especially if it is of a kind that is usually subjected to this usage, as are bank discounts. Wherever usury is forbidden, a bargain for compound interest would not be enforced. But it is common for courts to order a settlement of accounts with annual rests, which is equivalent to compound interest. This is especially done where trustees have used the money of their *cestuy que trust.*

UTAH, a territory of the United States, situated between lat. 37° and 42° N., and lon. 109° and 114° W.; general length N. and S., about 350 m.; general breadth, about 260 m.; area, 84,476 sq. m. It is bounded N. by Idaho and Wyoming, E. by Wyoming and Colorado, S. by Arizona, and W. by Nevada. It is divided into 20 counties, viz.: Beaver, Box Elder, Cache, Davis, Iron, Juab, Kane, Millard, Morgan, Piute, Rich, Salt Lake, San Pete, Sevier, Summit, Tooele, Utah, Wahsatch, Washington, Weber. Salt Lake City (pop. in 1870, 12,854) is the capital and largest city. The principal other places are Ogden (pop. 3,127), Provo (2,384), Morgan City (1,972), Logan (1,757), Spanish Fork (1,450), Mount Pleasant (1,346), Brigham City (1,315), Nephi City (1,286), Manti (1,239), Beaver City (1,207), Ephraim City (1,167), and Tooele City, Fillmore, Corinne City, Heber City, and Willard City, with more than 500 inhabitants each. The population of the territory, according to the United States censuses, has been as follows: in 1850, 11,380, including 24 free colored persons and 26 slaves; in 1860, 40,273, including 30 free colored persons, 29 slaves, and 89 Indians; in 1870, 86,786, including 118 colored persons, 445 Chinese, and 179 Indians. The tribal Indians (not enumerated in the census) numbered 1,040 in 1875, including 650 Uintah Utes on a reservation of 2,039,040 acres in the N. E. corner of the territory, together with 134 Pah Vants and 256 Goship Utes not under an agent. Of the total population in 1870, 56,084 were natives of the United States and 30,702 foreign born, 44,121 males and 42,665 females. Of the natives, 41,426 were born in the territory, 2,247 in New York, 2,105 in Illinois, 1,492 in Iowa, 1,315 in Pennsylvania, 1,133 in Ohio, and 908 in Missouri; and there were persons living in the territory born in every other state and nearly every territory. Of the foreigners, 20,772 were natives of the British isles, including 16,073 English, 502 Irish, 2,391 Scotch, and 1,783 Welsh; 4,957 of Denmark, 1,790 of Sweden, 687 of British America, 613 of Norway, and 509 of Switzerland. There were 15,344 males and 15,072 females between 5 and 18 years of age, 14,603 males between 18 and 45, and 18,042 males 21 and upward, of whom 10,147 were citizens of the United States and 7,895 unnaturalized foreigners. The number of families was 17,210, with an average of 5·04 persons to each; of dwellings, 18,290, with an average of 4·75 to each. Of persons 10 years old and upward, 2,515 could not read and 7,363 could not write, of whom 3,334 were natives and 4,029 foreigners. There were 29 blind persons, 18 deaf and dumb, 25 insane, and 23 idiotic. Of the 21,517 persons 10 years old and upward returned as engaged in all occupations, 10,428 were employed in agriculture, 5,317 in professional and personal services, 1,665 in trade and transportation, and 4,107 in manufactures and mining.—Utah is divided into two parts by the Wahsatch mountains, which cross it from N. E. to S. W. The W. part belongs to the Great Basin, its waters having no outlet to the ocean, while the E. part is drained by the Colorado river of the West. The surface is elevated; the valleys lie from 4,000 to 6,000 ft. above the sea, and the mountains attain an altitude of from 6,000 to upward of 13,000 ft., the highest peaks rising above the line of perpetual snow. The region E. of the Wahsatch range has a greater number of streams (which, however, nearly all flow through deep and precipitous cañons and are not generally available for irrigation) and is more rugged and mountainous than that W. of it. The Uintah mountains extend E. from the Wahsatch range along the S. border of Wyoming. The Roan or Book mountains lie partly in Utah and partly in Colorado, between the Grand and White rivers. The Little mountains are W. of Green river, and extend N. W. and S. E. between White and Uintah rivers, joining the Wahsatch range. The Sierra Lasal is S. E. of Grand river near the E. boundary, and S. of it are the Sierra Abajo and Orejas del Oso. The San Juan range and Sierra Panoche are near the S. boundary, the former W. and the latter E. of the Colorado river. The S. E. portion of the territory is less mountainous than the N. E., consisting of extensive undulating plateaus. W. of the Wahsatch range the country consists of a series of disconnected valleys, generally having a N. and S. direction, formed by ridges and mountain ranges, among which are the Thomas, Iron, Guyot, Goshoot, Pijarajabi, Oquirrh, and Raft River mountains. —The Colorado river is formed in Piute co. by the junction of the Grand and Green, and flows S. W. into Arizona. Its chief tributary from the east is the San Juan, and from the west the Dirty Devil. Green river enters the territory at the N. E. corner from Wyoming, and has a general S. course to its junction with the Grand. Its chief tributaries are the White river from the east, and Brush creek, Ashley's fork, Uintah, White, and San Rafael rivers from the west. Grand river enters from Colorado near the centre of the E. boundary, and flows S. W. to the Green. The S. W. corner of the territory is watered by the Rio Virgin, which flows S. W. and joins the Colorado in Nevada. W. of the Wahsatch mountains are several lakes, of which those with no outlet are impregnated with alkaline substances. The largest of these is Great Salt lake in the N. W. part of the territory. (See Great Salt Lake.) S. of this lake, into which it flows through the river Jordan, 45 m. long, is Utah lake, a sheet of pure fresh water abounding in fish. It is triangular, has an area of about 130 sq. m., and is closely bordered with mountains. Its chief tributaries are Salt creek from the south, Spanish fork from the southeast, and the Provo or Timpanagos river from the northeast. The principal tributaries of Great Salt lake, besides the Jordan, are the Ogden and Weber rivers on the east, and Bear river, which empties into Bear River bay in the northeast. Bear river rises at the junction of the Wahsatch and Uintah mountains near the S. W. corner of Wyoming, flows N. into Idaho, then bends N. W. and S., and reëntering Utah maintains a S. course to its mouth. Bear lake, partly in Idaho and partly in Utah, is connected with it. Sevier river has its sources in the S. part of the territory, flows N. for about 150 m., receiving several tributaries from the east, the most important of which is the San Pete, then bends S. W. and flows about 50 m. further into Sevier lake. The latter is 25 by 10 m. in greatest extent, about 100 m. S. S. W. of Great Salt lake. Beaver lake, S. E. of Sevier lake, receives the waters of Beaver river. Among other small lakes in this region are Little Salt lake and Fish lake; the latter contains fresh water, and is connected with Sevier river.—The principal geological formations are the cretaceous, triassic and Jurassic, tertiary, eozoic, alluvial, and Cambrian and Silurian. The cretaceous and triassic prevail in the southeast; the Wahsatch and Uintah mountains are cretaceous, triassic, and Cambrian; the extensive desert W. and S. W. of Great Salt lake is alluvial; while the rest of the territory is mostly tertiary. In the San Pete valley, 90 m. S. of Salt Lake City, are extensive deposits of coal. This is a lignite of superior quality and probably of cretaceous age. The coke from it, though inferior to that of the Pittsburgh coals, can be used in lead-smelting furnaces. Valuable deposits of the precious metals occur in the two mountain ranges between which the Jordan flows, the Wahsatch on the east and the Oquirrh on the west. These ranges are traversed by cañons, usually narrow and precipitous, opening into the Jordan valley, and affording access to the mining districts. The Utah Southern railroad, with several narrow-gauge branches, furnishes transportation to the smelting works in the valley and to Salt Lake City and Ogden. Lead ores, carrying silver, were discovered by Mormons in Beaver county in 1858, and large quantities of lead were produced, but the presence of silver was not then known. In 1863 silver-lead ores were discovered in Bingham cañon (Oquirrh range) by a party of the California volunteers. The early attempts to work these deposits were unprofitable, in the absence of skilled metallurgists and of railroad transportation. Gulch mining for gold in Bingham cañon began in 1868, and was continued with favorable results, in a limited field, for several years. The development in 1869 of the famous Emma deposit, in Little Cottonwood cañon (Wahsatch range), was the beginning of much excited activity in mining, in which even the Mormons, whose leaders had discouraged this industry, gradually took part. The large influx of miners from other territories, the construction of railroads, and the erection of more than 30 smelting and refining works, have widely developed the mining industry and brought about great political and social changes in the territory. The Emma mine, sold to an English company for £1,000,000, is said to have disappointed both the owners and the purchasers, and to be an irregular deposit in limestone, the available portions of which have been exhausted. The principal mining districts are as follows: Parley's Park, Big Cottonwood, Little Cottonwood, and American Fork, in the Wahsatch range; West Mountain or Bingham, Dry Cañon, Ophir, and Camp Floyd, in the Oquirrh range; Tintic and West Tintic, in the Tintic mountains; and South Star, North Star, San Francisco, and Lincoln, in the S. W. part of the territory. The ores are chiefly argentiferous carbonate of lead and galena, with some copper ore in the southern districts, and in a few localities ores sufficiently free from lead and other base metals to be successfully reduced by the Washoe process of stamping and pan amalgamation. The value of gold, silver, and lead produced in Utah since 1868, according to R. W. Raymond, United States commissioner of mining statistics, has been as follows:

YEARS.	Gold.	Silver.	Lead.	Aggregate.
1868–'9..	$600,000	....	....	$600,000
1870.....	300,000	$1,000,000	....	1,300,000
1871.....	221,000	2,079,000	$500,000	2,800,000
1872.....	100,008	2,345,279	675,477	3,120,764
1873.....	52,426	3,725,775	958,365	4,736,566
1874.....	92,093	3,819,508	1,430,044	5,341,645
1875.....	181,765	2,955,923	1,080,459	4,218,147
Total..	$1,547,292	$15,925,485	$4,644,345	$22,117,122

In 1875 there were also produced $102,148 worth of copper, $26,878 worth of iron, and $400,000 worth (50,000 tons) of coal. In the N. part of the territory, in the vicinity of Ogden and Brigham City, are numerous hot springs.—In the valleys the climate is generally mild and healthful, with little snow; the days are often hot in summer, but the nights are always cool; spring opens in April, and cold weather rarely sets in till December. On the mountains the winters are severe and the snowfall is more abundant, furnishing an unfailing supply of water for the streams in summer. There is considerable rain in the valleys from October to April, the weather during the rest of the year being dry, and rendering irrigation necessary to agriculture. The weather in spring and autumn is changeable. The annual precipitation of rain and melted snow varies from about 8 inches in the southwest to about 20 inches in the northeast. At Corinne on the Central Pacific railroad, N. E. of Great Salt lake, the mean temperature of the 12 months ending Sept. 30, 1872, was 49·2°; of the hottest month (July), 75°; of the coldest month (January), 26·6°; total rainfall, 17·13 inches. The mean temperature of the following 12 months was 48·18°; of the hottest month (July), 76·2°; of the coldest month (February), 24·3°; rainfall, 15·62 inches. The mean temperature of the year 1870 at Camp Douglas, near Salt Lake City, was 51·51°; of the hottest month (July), 76·45°; of the coldest month (December), 27·03°; maximum observed, 96°; minimum observed, 3°; rainfall, 15·1 inches. The valley of the Rio Virgin in the southwest is much warmer. The climate is generally healthful. The number of deaths reported by the census of 1870 is 891, of which 99 were from cholera infantum, 84 from pneumonia, 78 from fevers, 63 from consumption, 56 from measles, 52 from enteritis, and 46 from diarrhœa.—Much of the soil of Utah possesses the elements of fertility, and when irrigated produces good crops. In narrow belts around the lakes and springs and along the streams the moisture is sometimes sufficient without irrigation; but the plains in their natural state are for the most part hard, dry, and barren, frequently covered with a saline incrustation, and producing only sage brush and occasional tufts of sand grass and buffalo or gama grass. The mountain slopes in many parts are well covered with buffalo grass. The higher portions of the Wahsatch and Uintah mountains have a good growth of pine and fir, with some quaking ash, cedar, spruce, &c.; and there are considerable quantities of pine on the Oquirrh mountains, W. of Salt Lake City, on the range E. of Utah lake, and on the promontory in the N. E. part of Great Salt lake. Elsewhere there are no important forests, though occasional copses of willow, box elder, cottonwood, and dwarf ash occur along the streams. The principal settlements are along the W. base of the Wahsatch mountains and in the valley of the Rio Virgin, where by the construction of canals an extensive system of irrigation has been put in operation. The chief agricultural localities are the Malade valley; Cache valley, watered by Bear river; the Weber valley; Salt Lake valley, as the tract along the S. E. shore of Great Salt lake is called; the Jordan valley; Tooele valley, W. of the Jordan; the basin of Utah lake, especially on the east; Rush valley, W. of Utah lake; the San Pete valley; the Sevier valley; and the Rio Virgin valley. The region E. of the Wahsatch mountains is little known, but in the valleys of the Uintah and some other tributaries of the Colorado there is considerable irrigable land. The principal agricultural productions are wheat, oats, barley, potatoes, and other root crops. The nights are generally too cool for Indian corn, except in Salt Lake valley and the valley of the Rio Virgin. Apples, pears, peaches, plums, and grapes grow well. Large quantities of fruits, vegetables, and berries are dried or canned for shipment to Wyoming, Montana, Idaho, and Nevada. Cotton, figs, pomegranates, and other tropical fruits are grown in the Rio Virgin valley. The crops have frequently suffered from the devastations of locusts ("grasshoppers"). Utah presents fewer obstacles to grazing than to agriculture, large tracts impracticable to the farmer being well suited to the stock raiser. The buffalo and sand grass, and the wild sage when touched by frost, furnish nutritious food for cattle. Cache valley is one of the finest grazing districts, and in the valley of Green river there is an extensive region possessing superior advantages for sheep raising. The herdsmen drive their stock high up on the mountain slopes in summer, reserving the valleys for winter. Numerous herds are pastured on the mountain ranges E. of the Wahsatch in summer, and on the approach of winter are driven across that range into Salt Lake valley, where little shelter or prepared food is required.—According to the census of 1870, the number of acres of land in farms was 148,361, of which 118,755 were improved; number of farms, 4,908, of which 803 contained less than 10 acres each, 1,660 from 10 to 20, 2,019 from 20 to 50, 316 from 50 to 100, 107 from 100 to 500, and 3 more than 500; cash value of farms, $2,297,922; of farming implements and machinery, $291,390; wages paid during the year, including value of board, $133,695; estimated value of all farm productions, including betterments and additions to stock, $1,973,142; value of orchard produce, $43,938; of produce of market gardens, $8,700; of forest products, $800; of home manufactures, $56,891; of animals slaughtered or sold for slaughter, $172,382; of all live stock, $2,149,814. The productions were 543,487 bushels of spring wheat, 14,986 of winter wheat, 1,312 of rye, 95,557 of Indian corn, 65,650 of oats, 49,117 of barley, 178 of buckwheat, 9,291 of peas and beans, 323,645 of Irish potatoes, 163 of sweet potatoes, 5 of grass seed, 22 bales of cotton, 109,018 lbs. of wool, 310,335 of butter, 69,603 of cheese, 322 of hops, 10 of flax, 13 of wax, 575 of honey, 3,131 gallons of wine, 67,446 of sorghum molasses, and 27,305 tons of hay. The live stock on farms consisted of 11,068 horses, 2,879 mules and asses, 17,563 milch cows, 3,479 working oxen, 18,138 other cattle, 59,672 sheep, and 3,150 swine; besides which there were 3,213 horses and 151,754 cattle not on farms. The number of manufacturing establishments was 533, having 21 steam engines of 331 horse power, and 192 water wheels of 2,169 horse power; number of hands employed, 1,534; amount of capital invested, $1,391,898; wages paid during the year, $395,365; value of materials used, $1,238,252; annual value of products, $2,343,019. The principal establishments were 74 flouring and grist mills, value of products $782,846; 95 saw mills, $661,431; and 6 woollen factories, $133,620. The number of acres of land under cultivation in 1875 was reported at 347,750; bushels of wheat raised, 2,775,000; barley, 397,500; oats, 589,000; Indian corn, 300,000; potatoes, 1,807,000; tons of hay, 175,000; pounds of wool, 1,000,000; value of all agricultural products, $8,236,022; of manufactures, $2,803,985, nearly half flour. The value of imports into the territory, chiefly merchandise and manufactured articles, was $9,150,851; of exports therefrom, mineral and agricultural products, $6,435,858.—Utah communicates on the one hand with California and on the other with the east by the Central and Union Pacific railroads, which meet at Ogden in the north. From this point the Utah Central railroad extends to Salt Lake City, whence the Utah Southern runs S. to York and the Utah Western W. to Lake Point. The Utah Northern railroad extends from Ogden to Franklin, Idaho; the American Fork railroad, from American Fork on the Utah Southern E. to Deer Creek; the Bingham Cañon railroad, from Sandy on the Utah Southern to Bingham Cañon; the Wahsatch and Jordan Valley railroad, from Sandy to Fairfield; and the Summit County railroad, from Echo on the Union Pacific to Coalville. The following table gives the mileage of railroad in the territory in 1876:

LINES.	Miles in operation.
American Fork	16
Bingham Cañon	20
Central and Union Pacific	226
Summit County	8
Utah Central	37
Utah Northern	80
Utah Southern	78
Utah Western	25
Wahsatch and Jordan Valley	10
Total	500

There are two national banks, with a joint capital of $300,000.—The chief executive officers are a governor and secretary, appointed by the president with the consent of the senate for four years, and an auditor, treasurer, and superintendent of common schools, elected by the territorial legislature for two years. The legislature consists of a council of 13 and a house of representatives of 26 members, elected by the people by districts for two years, and has biennial sessions. The judicial power is vested in a supreme court, consisting of a chief justice and two associates; a district court in each of the three districts into which the territory is divided, held by a justice of the supreme court; and a probate court in each organized county. The justices of the supreme court are appointed by the president for four years; the probate judges are elected for two years. The supreme court has only appellate powers; the district courts are the tribunals of general original jurisdiction. While the government is thus similar to that of the other territories, the influence of the Mormon church is really paramount. By a territorial act of 1870 the right of suffrage was extended to women. The valuation of property, according to the United States census, has been:

YEARS.	ASSESSED VALUE.			True value of real and personal estate.
	Real estate.	Personal estate.	Total.	
1850.......	....	....	....	$986,083
1860.......	$286,504	$3,871,516	$4,158,020	5,596,118
1870.......	7,047,881	5,517,961	12,565,842	16,159,995

The taxation in 1870 was $167,355, of which $39,402 was territorial, $80,419 county, and $47,534 town, city, &c. The assessed value of property in 1875 was $23,289,180, and the territorial tax $58,222 95. The amount in the territorial treasury on Jan. 1, 1874, was $35,655 47; receipts during the following two years, $104,539 23; total, $140,194 70; disbursements during the same period, $139,662 46; balance, Jan. 1, 1876, $532 24.—The common schools are under the management of the territorial superintendent, county superintendents, and district trustees. A superintendent is elected in each county by the qualified voters for two years, and in each school district three trustees are elected for the same period by the resident taxpayers. Some money is raised by taxation, but the expenses of the schools are mainly defrayed by tuition fees. The following statistics are for 1875: number of districts, 236; number reporting, 163; schools, 296; children of school age (4 to 16), 35,696; pupils enrolled in public schools, 19,278; in private schools, 3,542; average attendance, public 13,462, private 2,437; amount paid public teachers, $95,533; paid for building purposes, $49,569; appropriated by territory, $15,000; raised by local taxation, $20,267; tuition fees, $95,533; value of public school property, $438,665. The university of Deseret, at Salt Lake City, was organized in 1869; it has medical, collegiate, normal, and inferior departments. It receives an annual appropriation from the territorial treasury of from $5,000 to $10,000. There are several good schools at Salt Lake City and one or two other points, maintained by various religious denominations. According to the census of 1870, there were 10 newspapers, issuing 1,578,400 copies annually, and having a circulation of 14,250. Of these 3 were daily, 3 semi-weekly, 3 weekly, and 1 monthly. The number of libraries was 133, with an aggregate of 39,177 volumes, of which 59, with 7,684 volumes, were private. There were 165 church organizations, with 164 edifices, 86,110 sittings, and property to the value of $674,600. Of the organizations only 5 were non-Mormon (2 Episcopal, 2 Methodist, and 1 Presbyterian).—Utah forms part of the territory acquired from Mexico in 1848. It was settled in 1847 by Mormons under the lead of Brigham Young. In March, 1849, a provisional government for the "state of Deseret" was organized, which was superseded by the territory of Utah, organized under the act of congress of Sept. 9, 1850, comprising 220,196 sq. m., and embracing portions of what is now Colorado, Wyoming, and Nevada. In 1856, under an act of the territorial legislature, a constitution was framed for the "state of Deseret," and application has since been repeatedly made to congress for its admission into the Union. (See MORMONS, and supplement.)

UTAH, a central county of Utah, containing Utah lake, and bordering E. on the Wahsatch mountains; area, about 1,000 sq. m.; pop. in 1870, 12,203. It comprises the finest portion of the territory; the soil is generally fertile and well cultivated. There are valuable gold mines. It is traversed by the Utah Southern and American Fork railroads. The chief productions in 1870 were 128,909 bushels of wheat, 31,123 of Indian corn, 18,824 of oats, 16,599 of barley, 75,069 of potatoes, 20,323 lbs. of wool, 63,624 of butter, and 7,051 tons of hay. There were 1,945 horses, 805 mules and asses, 6,464 cattle, 11,435 sheep, and 1,047 swine; 16 manufactories of sorghum molasses, 2 flour mills, and 12 saw mills. Capital, Provo.

UTAHS, or **Utes**, a large tribe of American Indians belonging to the Shoshone family, and roaming over a great part of New Mexico, Utah, Colorado, and Nevada. They are hunter tribes, hardy, athletic, and brave where game abounds; but some bands in sterile parts, where there are only sage rabbits, roots, seeds, &c., are wretchedly poor. The men wear long braided cues, while the hair of the women is short. Most of the work is done by women, and the Indians in some bands sell their wives and children to neighboring tribes. They are filthy in their habits, and their arms range from the original club, bow, and lance to good rifles. The principal bands of late years, for they vary, are the Tabequache, Muache, Capote, Weeminuche, Yampa, Grand River, and Uintah bands in Colorado and New Mexico; the Pi Edes, Pi Utes, Elk mountain Utes, and Shebe Ucher in the south and east of Utah; and the Weber Utes, Timpanagos, Sanpitches, Pahvants, and Goshutes in other parts of that territory. They have generally been friendly to the whites, though at times some bands have plundered emigrants on the plains. The bands in Utah were at first friendly to the Mormons, but after an attack by Walker's bands a body of volunteers defeated them, killing and taking many. A treaty was made with the Capotes in 1855, but some bands became hostile again. The Mohuaches declined to join the Mormons against the United States, but there was some fighting between the Utes and the miners at Pike's peak, and Winnemucca defeated Maj. Ormsby on Truckee river in a well fought battle. By a treaty made June 8, 1865, some of the bands ceded all their lands, the largest concession ever made by a tribe, and agreed to go on reservations; but a bad spirit soon became manifest. Black Hawk, a chief of the Pah Utes, for several years carried on a bloody warfare. Sanpitch, chief of the tribe so called, was arrested for aiding Black Hawk, and killed in endeavoring to escape; and in October, 1866, Col. Alexander defeated Ankotash, a Mohuache chief, killing many. In 1866 a treaty was made with the Grand River Utes and Tabequaches, to secure roads, &c. The reservation plan was carried out with so little judgment, that great suffering and general demoralization resulted. The treaty of 1865 guaranteed them $25,000 a year for 10 years, $20,000 for 20 years, and $15,000 for 30 years. The Goship Utes have $1,000 a year for 20 years under treaty of Oct. 12, 1863. It was found that valuable mines existed on the Ute reservation in Colorado, and under the act of April 23, 1872, for reducing the reservation, the secretary of the interior was authorized to contract with the tribe for a part of it. The Indians on the reservation, Tabequaches, Muaches, Capotes, Weeminuches, Yampas, Grand Rivers, and Uintahs, at last consented; and they ceded 4,000,000 acres for $25,000 a year for ever. Very soon however Miller, one of the Indian agents, was killed by two Utes, and this with theft of stock by the Capotes led to a collision between them and the troops. A careful census of the whole tribe in 1874 gave in Utah 8 bands of Pi Utes, numbering 528; 3 bands in northern Arizona, 284; 15 in southern Nevada, 1,031; 5 in S. E. California, 184; the Uintahs, Sanpitches, Timpanagos, and 4 other bands of Utes on the Uintah reservation, 556; the Pahvants of Utah, 134; and the Goshutes of Utah and Nevada, 460; 300 Chemehueves in California, who belong really to the Utes; the Pah Utes at Walker river, 6,000; at Southeast agency, 3,000; the Tabequaches, Capotes, Muaches, and Weeminuches, 3,199; and Peah's band, 350. Their property is chiefly in horses.

UTICA, an ancient city of Africa, on the W. arm of the river Bagradas, near the bay of Carthage, a short distance N. W. of the present city of Tunis; its site is now occupied by the little village of Bu-shatter. It is said to have been founded by the Tyrians 287 years before the foundation of Carthage. In the early wars between Rome and Carthage it appears as an ally of the latter. In the third Punic war it made a separate and early submission to Rome, and its prosperity was thereby greatly increased, as on the fall of Carthage a part of its territory was given to Utica, and that city was made the residence of the Roman governor. In the historical narratives of the struggles between Sulla and Marius, and those between Cæsar and Pompey, frequent references are made to it as a place of great importance. Its amphitheatre was capable of seating 20,000 persons, and on an artificial lake mimic sea fights were exhibited. Its supplies of water were stored in numerous vast reservoirs or cisterns, some of which still remaining are 136 ft. long, 19 ft. wide, and 20 or 30 ft. deep. Cato the younger, surnamed Uticensis, committed suicide here in 46 B. C. Augustus made Utica a free city. It was the see of a Christian bishop at an early date. It fell into the hands of the Vandals in 439, but was recovered by the Byzantine emperors, who retained it till toward the close of the 7th century, when it was conquered by the Arabs and destroyed.

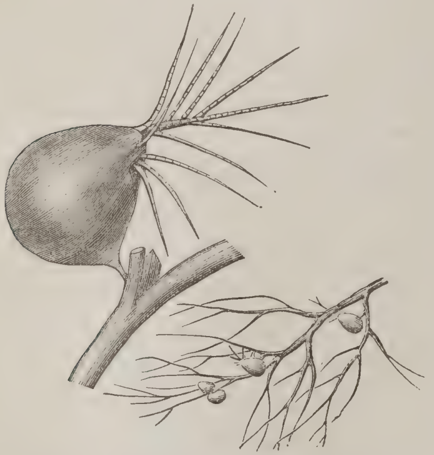
UTICA, a city and one of the county seats of Oneida co., New York, on the S. bank of the Mohawk river, at the junction of the Erie and Chenango canals, 83 m. (direct) W. N. W. of Albany and 45 m. E. of Syracuse; pop. in 1850, 17,565; in 1860, 22,529; in 1870, 28,804, of whom 9,849 were foreigners; in 1875, 32,070. The city is regularly laid out, and rises gradually from the river to the height of 150 ft. at the head of Genesee street, which has the principal shops and many elegant residences. The city hall on this street, erected about 1852, is of Milwaukee brick, and contains besides the city offices a court room for the United States courts, which hold a term here annually, and a commodious public hall. The city is lighted with gas, and is well supplied with water. It is at the intersection of the New York Central, the Utica and Black River, the Delaware, Lackawanna, and Western, and the New York and Oswego Midland railroads. Its trade in cheese is extensive. The manufactures amount to about $8,000,000 annually, embracing engines and boilers, machinery, iron and brass castings, pig iron, carriages, furniture, ale, organs, stone ware, fire brick, carpets, oil cloth, millstones, boots and shoes, cement, gloves, knit goods, lime, lasts, stained glass, agricultural implements, pumps, saws, rope, spring beds, silver ware, steam gauges, varnish, and japan. There are four national banks, with an aggregate capital of $1,500,000, a state bank, two private banks, and a savings institution. Utica is divided into ten wards, and is governed by a mayor and a board of aldermen of two members from each ward. It is the seat of one of the state lunatic asylums, which occupies a farm of 130 acres, with buildings that cost upward of $500,000. The other charitable institutions include the Faxton hospital, home for the homeless, industrial home for women, house of the Good Shepherd, St. John's orphan asylum, St. Elizabeth's hospital and home, St. Luke's home and hospital, St. Vincent's orphan asylum, St. Vincent protectorate, Utica dispensary, and Utica orphan asylum. The city has 17 public schools, including the free academy, with an average daily attendance of about 3,000 pupils, and 12 or 15 private schools and academies. The city library contains 6,055 volumes. Two daily, one tri-weekly (German), and five weekly (one Welsh) newspapers, and a quarterly ("American Journal of Insanity") and three monthly periodicals are published. There are 34 churches, viz.: 4 Baptist, 5 Episcopal, 1 Evangelical Association, 2 Evangelical Lutheran, 1 German Moravian, 1 Jewish, 6 Methodist, 5 Presbyterian, 1 Reformed, 5 Roman Catholic, 1 Universalist, 1 Welsh Calvinistic Methodist, and 1 Welsh Congregational.—The site of the city was included in the colonial grant styled Cosby's manor, made in 1734; but there was no settlement till after the revolution. Fort Schuyler was erected between the present Main and Mohawk streets, below Second street, in 1758, and a blockhouse was built before the close of the revolutionary war near the site of the present railroad depot. Till 1798 the village was called Old Fort Schuyler. In 1813 it had 1,700 inhabitants, and it grew very slowly till after the completion of the Erie canal. It received a city charter in 1832.

UTOPIA (Gr. *οὔ*, not, and *τόπος*, a place), the title of a political romance by Sir Thomas More, and the name that he gave to an imaginary island, which he represents to have been discovered by a companion of Amerigo Vespucci, and in which existed a perfect society. He pictured a community where all the property belonged to the government, to which every one contributed by his labor, receiving therefrom a supply of his wants; where the citizen rose through all the gradations of his existence from form to form, as if in a vast public school; where gold was contemned, and all the members of the society, unswerved by passion, were fixed each in his proper place. "Utopia" was published in Latin in 1516, and translated into English by Bishop Burnet.

UTRAQUISTS. See CALIXTINES.

UTRECHT. I. A province of the Netherlands, bounded N. by North Holland and the Zuyder Zee, E. by Gelderland, S. by Gelderland and South Holland, and W. by South Holland; area, 534 sq. m.; pop. in 1873, 179,465. The surface is level in the north and west, and varied in the southeast by low hills. It is well watered by the Rhine, and its branches the Vecht and Amstel. The air is less damp than in other parts of the Netherlands, and the climate is generally healthful. In the elevated parts the soil is sandy, and covered by extensive heaths and tracts of peat moors, but the low grounds are rich and fertile. **II.** A city, capital of the province, on the Crooked Rhine, which here divides into the Vecht and the Old Rhine, the principal branch assuming the latter name, 20 m. S. E. of Amsterdam; pop. in 1875, 64,275, about one third Roman Catholics. It is surrounded by forts, but the old ramparts are now used as boulevards. The mall, in the E. part of the city, is an exceedingly fine promenade. There are several canals and attractive squares, and many families of the Dutch aristocracy reside here. It has more than 20 churches, besides three cathedrals. Of the latter, the Reformed St. Martin's is the most remarkable for its fine Gothic architecture, and has seven chapels filled with monuments. Part of it was destroyed by a hurricane in 1674, and the tower is still detached from the main building. The government offices are in the so-called pope's house, built by Pope Adrian VI., who was born here (1459), in a house still standing. The once celebrated St. Paul's abbey is used for courts of law. Among other notable buildings are the national mint, a palace for arts and sciences, one formerly inhabited by King Louis Bonaparte, the renovated town hall, a large military hospital established by Napoleon I., and the William's barracks. The university, dating from 1636, is attended by about 500 students; among its adjuncts are a new physiological museum, a botanic garden, and a large library. Cigars, cotton, silk, linen, woollen cloth, carpets, and plush (Utrecht velvet) are made, and there are many publishing houses. Drinking water is shipped to Amsterdam. The city is the seat of a Roman Catholic archbishop and the old headquarters of the Jansenists, whose resident archbishop and whole congregation of 5,000 members joined the Old Catholics in 1874.—Utrecht is the oldest of all Batavian cities. The Romans called it Trajectum ad Rhenum and Ultrajectum; from the latter the modern name is derived. It belonged successively to the Frankish dominions and the German empire, and the union which laid the foundation of the republic of the seven United Provinces was organized here in 1579. The treaty of Utrecht, signed April 11, 1713, after long conferences, by the representatives of France, Great Britain, Holland, Prussia, Portugal, and Savoy, and subsequently completed by the peace of Rastadt (1714) and other treaties, formed an important era by ending the Spanish war of succession. By it Philip V., grandson of Louis XIV., was acknowledged as king of Spain; the Spanish Netherlands, Naples, Milan, and the island of Sardinia were left in the possession of the emperor Charles VI.; Sicily was given to Victor Amadeus II. of Savoy; and England obtained Gibraltar, Minorca, the Hudson Bay territories, Newfoundland, and Acadia, besides the recognition of the Protestant succession. (See *Le traité d'Utrecht*, by Charles Giraud, Paris, 1847.)

UTRICULARIA (Lat. *utriculus*, a little bladder), the bladderwort, a genus of aquatic or marsh plants, of which there are more than 100 species, some of which are found in nearly all parts of the world, there being over a dozen in the United States. The genus, with *pinguicula* and one other little known genus, forms what most botanists call the family *lentibulaceæ* (from *lentibula*, an old name for one species), but Hooker in his edition of Maout and Decaisne ("General System of Botany") gives the family the more appropriate name *utriculariea;* its affinities as to the structure of the flowers are with the figworts (*scrophulariaceæ*), and that of the fruit with the primroses (*primulaceæ*). A few of our species are found rooting in the muddy or sandy margins of ponds; these have minute awl-shaped leaves, and a slender stem bearing a solitary flower or a few flowers. The majority of them are floating aquatics, and are usually without roots; their branching stems are furnished with leaves divided into fine, capillary segments, bearing numerous small bladders, which at flowering time enable the plant to float near the surface and throw up its naked stems, which bear a few yellow or purplish flowers. The calyx is two-lipped; the monopetalous corolla two-lipped with a projecting palate, which often closes the throat; stamens two, with one-celled anthers; pistil with a one-celled free ovary, ripening into a several-seeded capsule.—The bladderworts have long been favorite plants with botanists, on account of their peculiar structure and the rarity of some of the species, but of late they have been invested with new interest from the fact that they must now be classed, with the closely related *pinguicula*, among insectivorous plants. It had been observed that the little bladders, which form such a striking feature of the floating species, contained minute crustaceans and other microscopic animals, and that their use was not solely, as had been supposed, to enable the plant to float and lift its flowers above the water. These hints induced Darwin to investigate the matter, and the results form two important chapters in his "Insectivorous Plants" (1875). About the same time Mrs. Mary Treat of Vineland, N. J., investigated the subject, and though most of her observations (published in the "New York Tribune," January, 1875) were anticipated by Darwin, she noticed some points that escaped him, which he quotes in the work referred to. Darwin's observations were made upon *U. neglecta*, which English botanists now regard as a subspecies of *U. vulgaris*, our most abundant bladderwort. The structure and action of the bladders require several pages and engravings for a full explanation. The bladders, of which there are two or three on the same divided leaf, are about one tenth of an inch across, and usually filled with water, though often containing bubbles of air; they are attached to the leaf by a short stalk, and, as shown by the enlarged engraving, are of a one-sided egg-shape. The mouth or opening usually points downward, and on the upper side terminates in two long appendages, each of which bears six or seven long bristles; these appendages, of which that on the near side only is shown in the engraving, Darwin terms antennæ; beneath these is the opening, with several other bristles on each side of it, and this is closed by a valve so arranged that it can only open inward; this valve is furnished with numerous glands, and the whole interior of the bladder is studded with processes, consisting of four unequal arms, which he calls quadrifid processes. The valve yields to a slight exterior pressure, the structure of the bladder being that of an admirably contrived trap for capturing microscopic creatures; and that it performs this office most effectively, the presence of animals or their remains in nine out of ten of the bladders is a proof. These creatures have been repeatedly seen by Mrs. Treat to enter the bladder, and she noted the time they remained alive after their capture; in most cases the before clear and transparent bladder became in less than two days so muddy from the decomposition of the animals that the contents could not be seen. Darwin has satisfied himself by experiments, given at length in the work referred to, that the utricularias capture these animals for nutriment.



Utricularia. Small branch with divided leaves and bladders, enlarged twice; a single bladder, greatly enlarged.

Common Bladderwort (Utricularia vulgaris).

UVALDE, a S. W. county of Texas, drained by the Rio Frio and its affluents; area, 1,000 sq. m.; pop. in 1870, 851, of whom 73 were colored. It has great advantages for stock raising, but is not well adapted to agriculture on account of the dryness of the seasons. The chief productions in 1870 were 18,225 bushels of Indian corn, 1,820 of sweet potatoes, 5,550 lbs. of butter, and 4,800 of wool. There were 162 horses, 24,778 cattle, 4,930 sheep, and 1,378 swine. Capital, Uvalde.

UVAROFF, Sergei Semenovitch, count, a Russian statesman, born in Moscow in 1785, died there in September, 1855. He studied in Göttingen, and was successively curator of the university of St. Petersburg and president of the academy of sciences, director of the department of trade and industry, and minister of education. He was made a count in 1846, and retired in 1848 on account of the restrictions on public instruction, which he had much promoted. More than any other Russian statesman he called into existence learned institutions, and laid the foundation of oriental studies and of the Asiatic department in the chancellery. His works have been collectively published under the titles of *Études de philologie et de critique* (St. Petersburg, 1843) and *Esquisses politiques et littéraires* (Paris, 1849), including his *Notice sur Gœthe.*

UVULA, a conical fleshy appendage, hanging down toward the tongue from the border of the soft palate, on the median line. It is made up of muscular substance, covered by mucous membrane; from it arise on each side two folds, called the pillars of the fauces, between which, on the back part and sides of the throat, are the tonsils. It varies in size and length in different individuals, but is generally one half to three quarters of an inch long; it is sometimes so long as to rest upon the tongue, causing harassing cough from its continued tickling, requiring the use of astringent gargles or even a partial excision. Its function is supposed to be that of affording, by the contraction of its muscular fibres, a firm point of support upon the median line to the lateral muscles of the soft palate when this organ is stretched across the upper part of the pharynx in deglutition, shutting off the communication between the pharynx and the posterior nares.

UWINS, Thomas, an English painter, born in London in 1783, died at Staines, Middlesex, Aug. 25, 1857. In early life he designed for illustrated works, and prepared copies for engravers. Subsequent to 1826 he painted a popular series of pictures illustrating the social life of the Italian peasantry. He also painted English and French peasant pieces and illustrations from sacred and profane history. In 1836 he was elected a royal academician; and for several years he was keeper of her majesty's pictures and of the national gallery.

UZBECKS, a people of Turkistan, belonging to the Turkish or Tartaric branch of the Turanian race, of which they are the most civilized tribe in that country, and constituting the dominant native population in Khiva, Bokhara, and Khokan. The typical Tartar characteristics of the Kirghiz are modified in the Uzbecks, probably by the introduction of an Aryan element. They are tall, muscular, and well formed, ruddy in complexion, with broad noses flattened at the end, receding foreheads, and but little beard. Although many of the Uzbecks still live as nomads, the larger number belong to the class known as Sarts or settled inhabitants of Turkistan, and dwell in or about the principal towns, where their military, official, and social influence has induced many persons of different race to assume their name. The population, according to a Russian estimate, numbers 1,500,000 persons. In the time of Timour, about the end of the 14th century, the Uzbecks dwelt N. of the Jaxartes, whence they subsequently overran Bokhara. The purest specimens of the people are met with in Khokan. They are bigoted Mohammedans.

UZZIAH, or Azariah, a king of Judah. See HEBREWS, vol. viii., p. 588.

V

V, THE 22d letter and 17th consonant of the English alphabet. It was anciently called U consonant. Though found on the most ancient Roman monuments of which we have any knowledge, and even in Etruscan and Samnite inscriptions, it was unknown, according to Tacitus, to the primitive alphabet of the Latins. The same character was used to represent both U and V, these letters also being frequently interchanged (see U); and when the emperor Claudius, as Suetonius relates, wished to introduce a separate sign for the sound of V, he made choice of the inverted digamma, Ⅎ. In the inscriptions of the Etruscans and other primitive inhabitants of Italy, V is frequently confounded with the Æolian digamma, Ϝ, through which it claims relationship with the Semitic *vav.* Among the Hebrews, too, and probably also among the Phœnicians, the corresponding letter was employed both as consonant and vowel. The present form of V is derived from the Greek *upsilon* (Υ), which is sometimes represented without the stem or vertical bar.—Besides *u,* this letter is interchanged with *b, f,* and *m.* The Hebrew *beth* sometimes had a sound approaching that of V, and the Greek *beta* (β) is pronounced by the modern Greeks *vita.* The Spanish and Portuguese B, too, is in many cases pronounced like V. In German V is pronounced like F. (See B, and F.) The change with *m* is noticed chiefly in Welsh, in which tongue *Roman* becomes *Rofan* (pronounced Rovan), while for the Latin *amnis,* river, the Welsh equivalent is *Afon.*—V as a numeral denotes 5, or with a dash over it ($\overline{V}$), 500. On old French coins it signifies the mint of Troyes.

VACA, Cabeça de. See NUÑEZ, ALVAR.

VACCAJ, Nicolò, an Italian composer, born at Tolentino in the Papal States in 1791, died in Milan in 1849. He was a pupil of Paisiello at Naples, and from 1811 to 1820 wrote operas, cantatas, and ballets, which had a moderate success. He then taught singing in Venice, Trieste, and Vienna, and wrote *Pietro il Grande*, a comic opera performed at Parma, *Zadig ed Astartea*, performed at Naples, and *Giulietta e Romeo*, performed at Milan, his best work. He afterward taught singing in Paris and London, but returned to Italy in 1832, and in 1838 became first master of composition at the conservatory of Milan, which post he held till his death.

VACCARO, Andrea, an Italian painter, born in Naples in 1598, died there in 1670. He was a pupil of Stanzioni, after whose death he was at the head of the Neapolitan school. One of his best works is a "Holy Family" in the church of Santa Maria degli Angeli at Naples.

VACCINATION (Lat. *vacca*, a cow), inoculation for cowpox as a protection against smallpox, first practised by Dr. Edward Jenner in 1796. (See JENNER.) On the 2d or 3d day after virus taken from a perfect vaccine vesicle, whether from the cow or the human subject, is placed in contact with the denuded dermis or true skin, the puncture is observed to be slightly inflamed. On the 4th or 5th day a vesicle is observed surrounded by a slight blush of inflammation, and containing a little colorless, transparent fluid. This increases until the 8th day, when it should be from a quarter to half an inch in diameter, the blush of inflammation surrounding it at the same time having become more marked. The vesicle is umbilicated, that is, its centre is depressed below the level of the circumference, in this respect resembling the pustules of smallpox. It is compound, being made of 10 to 14 distinct cells; one of these, carefully punctured, discharges a minute drop of fluid, leaving the other cells still distended. On the 8th day the blush of surrounding inflammation, heretofore very slight, begins to extend, forming what is termed the areola; it attains its greatest diameter by the 11th day, after which it gradually fades and disappears. With the appearance of the areola the vesicle becomes darker and dryer, and gradually concretes into a brown translucent crust, which falls off about the 20th day, leaving a circular depressed cicatrix. About the 8th or 9th day there is usually some slight febrile disturbance, though it is often scarcely noticeable. Such is the course of the true vaccine vesicle when uninterfered with, either by the presence of constitutional disease or by the accidental occurrence of inflammation.—When vaccination was first introduced, it was believed that it would afford in all cases complete and permanent protection from smallpox. But it was discovered that those who had been well and thoroughly vaccinated were still liable to some extent to attacks of smallpox; and though in general the disease was modified (varioloid) and rendered shorter and milder, still it occasionally resulted in death. The degree of protection afforded by vaccination thus became a question of great interest. Its extreme value was easily demonstrated by statistical researches. In England, in the last half of the 18th century, out of every 1,000 deaths, 96 occurred from smallpox; in the first half of the present century, out of every 1,000 deaths, but 35 were caused by that disease. The amount of mortality in a country by smallpox seems to bear a fixed relation to the extent to which vaccination is carried out. In all England and Wales, for some years previous to 1853, the proportional mortality by smallpox was 21·9 to 1,000 deaths from all causes; in London it was but 16 to 1,000; in Ireland, where vaccination was much less general, it was 49 to 1,000, while in Connaught it was 60 to 1,000. On the other hand, in a number of European countries where vaccination was more or less compulsory, the proportionate number of deaths from smallpox about the same time varied from 2 per 1,000 of all causes in Bohemia, Lombardy, Venice, and Sweden, to 8·33 per 1,000 in Saxony. Although in many instances persons who had been vaccinated were attacked with smallpox in a more or less modified form, it was noticed that the persons so attacked had been commonly vaccinated many years previously. The mere lapse of time in many cases seems sufficient to destroy the protective influence of vaccination. The duration of the protective influence varies with different individuals. The same thing happens with regard to the protective influence of an attack of smallpox itself; in most persons it lasts for life; many, after a period more or less prolonged, are liable to a second attack; while cases have occurred in which a third attack has proved fatal. In all cases revaccination seems to be a test of the loss or presence of the protective influence; to render this test certain, where revaccination does not succeed on the first trial, it should be carefully performed a second time. In the Prussian army in 1848, 28,859 individuals were revaccinated, in 6,373 of whom the cicatrices of the preceding vaccination were indistinct or invisible. Of these, 16,862 had regular vesicles, 4,404 irregular vesicles, and in 7,753 cases no effect was produced. On a repetition of the vaccination in these last, it succeeded in 1,579 cases. Among the whole number successfully revaccinated either in 1848 or before, there was but a single case of varioloid, and not one case of smallpox; while seven cases of varioloid occurred either among the recruits or among those revaccinated without success.

VACHEROT, Étienne, a French philosopher, born in Langres, July 29, 1809. He studied at the normal school in Paris, and was director of studies there from 1837 to 1851, when he was suspended through ultramontane influence. In 1852 he was dismissed for refusing to take the oath to Napoleon III.; and for his treatise *La démocratie* (1859) he underwent three months' imprisonment, and for this and his refusal to act as a member of the council of superior instruction was disfranchised till 1870. In 1871 he was elected a member of the national assembly. He succeeded Cousin in the academy. His works include *Histoire critique de l'école d'Alexandrie*, crowned by the academy (3 vols., 1846-'51); *La métaphysique et la science* (2 vols., 1858; 2d ed., 3 vols., 1863); *Essais de philosophie critique* (1864); and *La religion* (1868).

VAGA, Perino del, or **Pietro Buonaccorsi**, an Italian painter, born in Florence in 1500, died in Rome in 1547. He adopted the names of his teachers Vaga and Perino, and was employed by Raphael on some of the principal designs in fresco for the Vatican. After the death of Raphael he rose into great reputation. In 1527, during the sack of Rome, he was imprisoned; and on being ransomed he went to Genoa, where he embellished the palace of the Dorias. He returned to Rome during the pontificate of Paul III. He designed after the style of Michel Angelo, and excelled in mythological, classical, and religious subjects. His best work is the "Creation of Eve" in Rome.

VAGRANT (Lat. *vagari*, to wander), in law, sometimes defined as one who has no settled home, but more properly one who wanders about without any settled home, refuses to work, and has no means of subsistence. The law looks upon vagrancy as an offence, not for its moral wrong nor for the harm it does to the man himself, but for its injury to society, and the demand it makes upon the means of society for the subsistence of the vagrant. If one having a settled home, without means of subsistence, requires help, he is a pauper, and not a vagrant; that is, he is entitled to aid, but is not an offender. Neither is one a vagrant who, having means of his own, leads a life of idle wandering, but makes no call upon the public means, and inflicts no direct injury upon the public welfare. Vagrancy has been a statutory offence from a very early day, and it was probably an offence at the common law.

VAILLANT, François Le. See LE VAILLANT.

VALAIS (Ger. *Wallis*), a S. W. canton of Switzerland, bounded N. by Vaud and Bern, E. by Uri and Ticino, S. E. and S. by Piedmont, and S. W. and S. by Savoy; area, 2,026 sq. m.; pop. in 1870, 96,887, nearly all Roman Catholics. Valais is one of the most picturesque of Swiss cantons, being surrounded on all sides by some of the loftiest mountains, such as the Monte Rosa group (highest peak, 15,150 ft.) and the Matterhorn (14,835 ft.), both belonging to the Pennine Alps and separating Valais from Italy; and besides other branches of these Alps S. and W., there are those of the Helvetian or Lepontine Alps on the east, and their divergent branch known as the Bernese Alps on the north. Among over 100 glaciers in this canton, which are best seen from the valleys descending into it from Monte Rosa, are several of great extent and magnificence, especially the Gorner ice stream and the Viescher glacier, forming an ice cataract, and the Aletsch, the largest of all the glaciers, separated by a ridge from the Eggischhorn, one of the present headquarters of high Alpine explorations. The Sallenche waterfall adjoins Martigny, the starting point of the roads over the Great St. Bernard and Col de Balme passes. The new road over the Furca pass, completed in 1867, directly connects the St. Gothard group with the valley of the Rhône, the principal valley in this canton, and has greatly increased the traffic across the Alps from Upper Valais. Several other great and minor passes, such as the Grimsel near the Rhône glacier, the Gemmi near the mineral springs of Leuk, and others, are in part or wholly in this canton. The chief occupation is the rearing of cattle, in connection with dairies. Grapes and figs ripen at the foot of ice-clad mountains, and wine is produced in the central and lower parts of the canton. The crops of maize have lately increased, as well as the mineral productions. Emigration to the United States has much increased since 1868. The country is generally divided into Upper and Lower Valais. French, in a corrupt form, is spoken by a majority of the inhabitants.—Valais was long ruled by Bern; it became a separate canton under the Helvetic constitution of 1798, was subsequently annexed to France, and after the fall of Napoleon was again admitted as a canton. It joined in the movement which led to the formation of the Sonderbund in 1843, and after its overthrow in 1847 adopted a liberal constitution, which was modified in 1852 through the ultramontane influence of Upper Valais. The grand council consists of 85, and the council of state of 7 members, the former initiating laws and the latter carrying them out. The Roman Catholic bishop resides at Sion or Sitten, the capital.

VALCKENAER. I. Lodewijk Casper, a Dutch scholar, born in Leeuwarden in 1715, died in Leyden, March 14, 1785. He became professor of Greek at Franeker in 1741, and also of Grecian antiquity in 1755, and from 1766 held those two chairs together with that of Dutch history at Leyden. He edited the works of several of the classical authors, and wrote a number of critical and other treatises, a collection of which was published by Erfurdt under the title *Opuscula Philologica, Critica et Oratoria* (2 vols. 8vo, Leipsic, 1809). **II. Jan**, a Dutch statesman, son of the preceding, born in Leyden about 1759, died in Haarlem, Jan. 25, 1821. He was professor of jurisprudence successively at Franeker and Utrecht, but, being an active leader of the anti-Orange party, was compelled to leave Holland in 1787. After soliciting the coöperation of France, he accompanied the French auxiliary troops under Pichegru to the Netherlands in 1794–'5, and became a member of the legislative body of the new republic and professor of public law at Leyden. In 1796 he went as ambassador to Spain. In 1810 he attempted in vain, as an envoy of King Louis Bonaparte, to dissuade Napoleon from annexing Holland to France.

VALDEZ. See MELENDEZ VALDEZ.

VALDIVIA. **I.** A S. province of Chili, bordering on the province of Arauco, the Andes (which separate it from the Argentine Republic and Patagonia), Llanquihue, and the Pacific ocean; area, 10,700 sq. m.; pop. in 1875, 37,481. There are many fine harbors on the coast. On the E. border are several active volcanoes, of which Villarica is the highest. The surface between the sea and the Andes is generally more level than that of other parts of Chili. The most important streams are the Cauten or Imperial, Tolten, Valdivia, and Rio Bueno. The soil is exceedingly fertile, and the greater part is covered with forests of excellent timber. The climate is moist, but healthful. Valdivia at one time yielded large quantities of gold, but the system of slavery which the Spaniards attempted to impose upon the natives caused a revolt, which led to the ruin of the mines. About two thirds of the population are Araucanian Indians, and the remainder descendants of the Spaniards and mixed breeds. **II.** A city, capital of the province, on the S. side of the Valdivia river, about 9 m. from the Pacific, and about 470 m. S. of Santiago; lat. 39° 49′ S., lon. 73° 15′ W.; pop. in 1875, 4,054, many of whom are Germans. The harbor, a beautiful bay formed by the river, is one of the best on the Pacific. The island of Manzera at the entrance to the river forms two passages, skirted by steep mountains strongly fortified. Its chief trade is with Valparaiso, to which it exports large quantities of timber. It was founded in 1551 by Pedro de Valdivia, became rich and populous, was many times attacked and in 1590 destroyed by the Araucanians, and was rebuilt and strongly fortified. It was taken by the Dutch in 1640, and by the patriots under Lord Cochrane in 1820.

VALENCE (anc. *Valentia*), a town of France, in Dauphiny, capital of the department of Drôme, on the left bank of the Rhône, which is here spanned by an unusually fine suspension bridge, 57 m. S. of Lyons; pop. in 1872, 20,668. The streets are narrow, and old walls surround the town; but there are attractive squares and promenades. It is a bishop's see, and has a cathedral founded in 212 by St. Apollinaris, with a tower rebuilt in 1862, and with Canova's monument of Pope Pius VI., who died here. Connected with the artillery school is a large area for practice. The former citadel is now a barrack for engineers. Silk and cotton goods, gloves, glass ware, and other articles are manufactured. There is much trade in the sparkling St. Peray wine, almost equal to Champagne, and in timber, grained leather, cloth, &c.—The town was a colony in Gallia Narbonensis, and in the middle ages was the capital of the county and duchy of Valentinois.

VALENCIA, a central county of New Mexico, divided into two parts by the S. projection of San Miguel co.; area, about 10,500 sq. m.; pop. in 1870, 9,093. The E. part borders on Texas, and is intersected in the S. W. corner by the Rio Pecos. The W. part, bordering on Arizona, is intersected near the centre by the Rio Grande, and watered by its tributary the Puerco, and by the Zuñi, one of the head streams of the Colorado Chiquito, and is crossed by several mountain chains. The chief productions in 1870 were 39,438 bushels of wheat, 77,854 of Indian corn, 5,755 of peas and beans, 6,178 lbs. of tobacco, and 72,840 of wool. There were 456 horses, 622 mules and asses, 1,264 milch cows, 3,329 working oxen, 48,610 sheep, and 795 swine. Capital, Valencia.

VALENCIA. **I.** An ancient kingdom of Spain, bounded N. by Catalonia, E. and S. E. by the Mediterranean, S. W. by Murcia, W. by New Castile, and N. W. by Aragon; area, 8,897 sq. m.; pop. in 1870, 1,401,833. It comprised the modern provinces of Castellon, Valencia, and Alicante. The principal rivers, all of which rise in the country W. of Valencia, are the Guadalaviar, the Jucar and its tributary the Magro, the Palancia, Mijares, and Segura. The interior parts are mountainous, while the land upon the coast and on the banks of the numerous rivers is generally level. In some places high rugged mountains come close to the sea. The Sierra de Penaquila, which terminates in Cape San Martin, traverses the province of Alicante in a N. E. direction. The other ranges are irregular, but for the most part lie nearly E. and W. The ores of iron, copper, cobalt, quicksilver, lead, and silver are found. Superior facilities for irrigation render Valencia the most fertile district of Spain, and in some places several crops are raised in a year. Wine is produced in large quantities. The climate is noted for its mildness and salubrity.—Under the Moors Valencia formed part of the caliphate of Cordova, but it was taken from them by the Cid in 1094. They reconquered it in 1101, and on the dissolution of the realm of the Almoravides it became an independent kingdom; but the Moors were finally expelled in 1238. It afterward became a province of the kingdom of Aragon, retaining however the title of *reino de Valencia.* **II.** A province occupying the centre of the ancient kingdom, bordering on the Mediterranean and the provinces of Castellon, Teruel, Cuenca, Albacete, and Alicante; area, 4,352 sq. m.; pop. in 1870, 665,141. The rivers Guadalaviar and Jucar, which intersect it, supply a system of irrigating canals, watering more than 100,000 acres. The chief crops of the irrigated lands are wheat, barley, oats, rye, lucerne, maize, beans, hemp, rice, oranges, and mulberries; of the unirrigated lands, the grape, olive, carob, fig, date, and esparto grass. About 4,000 acres are devoted to orange culture, which has become very important. The mountainous districts are clothed with forests of fine timber, and there are valuable marble quarries in the interior and fisheries on the coast. Large numbers of sheep and goats are raised, and the silkworm is extensively cultivated. **III.** A city (anc. *Valentia*), capital of the province and of the ancient kingdom, on the river Guadalaviar, about 2 m. from the sea, 190 m. E. S. E. of Madrid; pop. about 110,000. The old city is surrounded by a circular wall, built in 1356, 30 ft. high and 10 ft. thick, which has eight gates. Its streets are crooked and narrow, and the houses high and gloomy; but the suburbs beyond the walls are handsomely laid out and well built. A quay planted with shade trees extends along the river, which is crossed by five bridges. Among the public buildings are the cathedral, begun in 1262 and enlarged in 1482, the interior of which is richly adorned with marbles and many fine pictures; the episcopal palace, custom house, chamber of commerce, court house, theatre, academy of the fine arts, school of commerce, medical institute, several hospitals and asylums, and many churches and suppressed convents. The university, founded in 1410, has a library of about 45,000 volumes and a museum of natural history, and there is another library of 11,000 volumes in the bishop's palace. The national museum, in one of the suppressed convents, contains several hundred paintings of the Valencian school. The botanic garden has the finest collection of exotic plants in Spain. The fashionable promenade is the Alameda, whose long avenue, adorned with fountains and trees, leads to the Grao or port of Valencia. The harbor is formed by a semicircular curve in the beach, ½ m. in diameter, with two moles extending seaward, one 5,833, the other 3,589 ft. long. An inner port is formed by two arms extending from the moles across the curve, and enclosing an area of 110,000 square yards. It is defended by two batteries of 12 guns each, situated on the shore on each side of the Grao. The principal manufactures of Valencia are silks, linen and woollen goods, bagging and cordage, hats, gloves, fans, combs, leather, glass, paper, painted tiles, soap, iron ware, and pottery. The exports are oranges, nuts, raw silk, wine, esparto, raisins, and saffron. Of these, oranges form the most important item; the export of the crop of 1873–'4 was 523,717 cases, of which Great Britain took 440,859 cases, and the United States 60,964. During the same season 163 steamers engaged in the orange trade loaded in the port. The wine is shipped chiefly to France. The total value of the exports to the United States for the year ending Sept. 30, 1874, was $332,392. About 3,000 vessels, native and foreign, visit the port annually.—Valencia was a town of the Edetani in Hispania Tarraconensis. At a later period it became a Roman colony, in which D. Junius Brutus settled the soldiers of Viriathus about 138 B. C. It was destroyed by Pompey, but was soon restored. The Moors took it from the Goths in 713, and it was captured from them in the spring of 1094, after a siege of 20 months. In 1101 they retook it, but were forced to surrender it in 1238. In the war of the succession Valencia was opposed to the French, in consequence of which it lost its privileges in the reign of Philip V. In June, 1808, the French, under Gen. Moncey, attempted to take it; but though it was abandoned by the generals and nobles, the people, under Rico, a monk, made a gallant defence, and compelled the enemy to retire with great loss. It was afterward (Jan. 9, 1812) surrendered to Suchet by the Spanish general Blake.

VALENCIA, a city of Venezuela, capital of the province of Carabobo, in a valley between the sierras San Diego and Guataparo, 18 m. from Puerto Cabello, its seaport, and 70 m. W. S. W. of Carácas; pop. in 1873, 28,544. In 1810 it was 3 m. W. of Valencia lake, which has so diminished from evaporation that it is now nearly 9 m. distant. The streets are broad and laid out at right angles to each other, but most of the houses are low and mean. There are no public buildings worthy of note, excepting the principal church, which stands in a large square. A brisk trade is carried on through Puerto Cabello, with which it is connected by a good road.—Valencia was founded in 1555. In 1558 it was attacked by Indians, who were repulsed with great loss. It suffered from the earthquake of 1812, and subsequently from the war of independence.

VALENCIENNES (under the Merovingians *Valentianæ*), a town of France, in the department of Le Nord, at the confluence of the Scheldt and Ronelle, 27 m. S. E. of Lille; pop. in 1872, 24,662. Its fortress, built by Vauban, is on an island in the Scheldt. It has a college, a school of chemistry, an academy for painting and sculpture, and a public library. The chief manufactures are linen, muslins, beet sugar, gold and silver tissues, toys, earthenware, and leather. The production of Valenciennes lace has much declined. The mines in the vicinity yield one fourth of the total French product of coal.—Valenciennes was a residence of the Merovingian kings, became one of the chief towns of Hainaut, and was unsuccessfully besieged by Louis XI. in 1477 and Turenne in 1656; but it was captured by Louis XIV. in 1677, and its possession was confirmed to France by the treaty of Nimeguen. It was taken by the allies in 1793 after a siege of six weeks, but recaptured in 1794. The Prussians occupied it from August, 1815, to November, 1818.

VALENCIENNES, Achille, a French naturalist, born in Paris, Aug. 9, 1794, died there, April 14, 1865. In 1830 he became professor of anatomy in the normal school. In 1844 he succeeded Geoffroy Saint-Hilaire in the academy of sciences. His works include *Histoire* *naturelle des poissons*, commenced with Cuvier (11 vols., Paris, 1829–'49), and *Histoire naturelle des mollusques, des annélides et des zoophytes* (1833).

VALENS, Flavius, a Roman emperor of the East, born about A. D. 328, killed at Adrianople, Aug. 9, 378. In March, 364, his brother Valentinian I. made him emperor of the East. In the following year Procopius was proclaimed emperor by the people of Constantinople, and met and defeated Valens at Chalcedon; but in 366, after two successful battles, Valens captured Procopius and slew him. After reducing the taxes one fourth, and being baptized, in 367 he began a war with the Goths who had assisted Procopius, and at first was successful, compelling Athanaric to sue for peace. Returning in triumph, he began a desultory war against the Persians, chiefly in defence of Armenia. In the mean time the Goths, retiring before the Huns, had been permitted to settle in Mœsia; but they soon became discontented, ravaged Thrace and Macedonia, and defeated the Romans in several battles. The last of these, at Adrianople, in which Valens perished, was one of the severest reverses the Romans ever experienced.

VALENTIN, Gabriel Gustav, a German physiologist, of Jewish parentage, born in Breslau, July 8, 1810. He took his degree in medicine at Breslau in 1832, and in 1836 became professor of physiology at Bern. His works include *Lehrbuch der Physiologie des Menschen* (2 vols., Brunswick, 1845; 2d ed., 1847–'50); *Grundriss der Physiologie des Menschen* (1846; 4th enlarged ed., 1855); and *Versuch einer physiologischen Pathologie des Blutes und der übrigen Körpersäfte* (Leipsic, 1866).

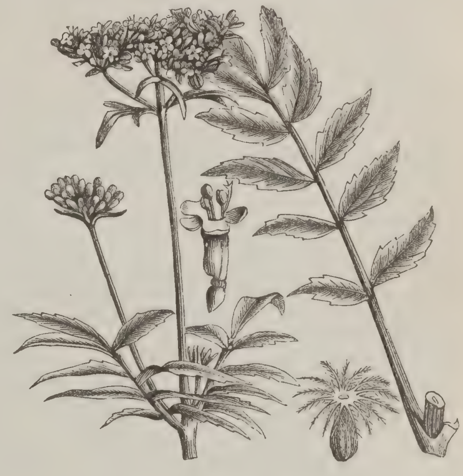
VALENTINE, Saint, according to some ecclesiastical writers a bishop, according to others a presbyter, who was beheaded at Rome in the reign of the emperor Claudius (270), and was early canonized. Wheatley says that St. Valentine "was a man of most admirable parts, and so famous for his love and charity, that the custom of choosing Valentines upon his festival (which is still practised) took its rise from thence." Others derived the custom from birds being supposed to select their mates on this day; others from a practice prevalent in ancient Rome at the festival of the Lupercalia, during the month of February, when, among other ceremonies, the names of young women were placed in a box, from which they were taken by young men, as chance directed. The pastors of the early church, finding it impossible to extirpate this pagan ceremony, changed its form. It was the custom on the eve of Feb. 14, St. Valentine's day, to have the names of a select number of one sex put into some vessel by an equal number of the other; and thereupon every one drew a name, which for the time being was called his or her Valentine. The custom of choosing Valentines existed very early. Presents of gloves, garters, and jewelry were common as valentines.

VALENTINIAN (VALENTINIANUS), the name of three Roman emperors. **I. Flavius,** born at Cibalæ, Pannonia, in A. D. 321, died at Bregetio, in the same province, Nov. 17, 375. He was the son of Count Gratian, and on the accession of Jovian in 363 he was made captain of the second company of the guards. On the death of Jovian at Dadastana in February, 364, the throne was offered by the army leaders to Valentinian, who was then at Ancyra. He assumed the purple on the plains of Nicæa, Feb. 26, and after reaching Constantinople made his brother Valens associate emperor with the control of the eastern provinces. Valentinian then went to Italy, and for some years was engaged in protecting the frontiers of the empire. He first fixed his headquarters at Lutetia (now Paris), and during 366 the Alemanni were defeated by his general Jovinus, the master of the horse. The following winter was spent at Durocortorum (Rheims), in building forts and taking other means of defence against the incursions of the Germans. In 367 the Alemanni surprised and plundered Moguntiacum (Mentz); but the emperor drove them back into their own country, defeating them at a place called Solicinum. In 370 the Saxons, who had made an incursion into Roman territory, were destroyed by an ambuscade. In 374 Valentinian prepared for a campaign against the Quadi, but died at Bregentio, near the modern town of Comorn, as he was on the point of setting out. He was one of the ablest of the Roman emperors, but his character was disfigured by passion and cruelty. He was succeeded by his son Gratian. **II. Flavius,** son of the preceding, born about 371, strangled May 15, 392. Immediately on the death of his father, he was raised by the army to the imperial dignity, being but four or five years old; and although his brother Gratian consented to this arrangement, and made a partition of the western empire, assigning to Valentinian Italy, Illyricum, and Africa, Gratian really exercised the supreme authority over all the territory until his murder in 383. Then Theodosius took charge of Valentinian, and upheld his rights in 387 and 388 against the usurper Maximus. In 392 he endeavored to rid himself of his general and chief adviser Arbogast by dismissal, and a few days later was found strangled in his apartment at Vienna in Gaul. **III. Placidius,** emperor of the West, born about 419, assassinated in 455. He was the son of Constantius and Galla Placidia, daughter of Theodosius I. On Oct. 23, 425, he received from his cousin Theodosius II. the purple and the title of Augustus. The first years of his reign, while his mother Placidia ruled for him, were marked by the disastrous rivalry between the last two great Roman generals, Aëtius and Boniface, and the consequent loss of Africa. In 437 Valentinian married at Constantinople Eudoxia, daughter of Theodosius. In the mean time the extreme provinces of the western empire were gradually attacked on all sides, and the Roman possessions were constantly diminishing. In 451 Aëtius defeated Attila near Châlons-sur-Marne; but in 452 the latter ravaged the north of Italy. Aëtius was in 454 killed by Valentinian's own hand, whose feeble mind had long been jealous of the commanding intellect and haughty character of his greatest general. Valentinian himself, the following year, while viewing a spectacle in the Campus Martius, was slain at the instigation of the patrician Petronius Maximus, whose wife the emperor had a short time before violated, and who usurped the throne. Valentinian was the last of the Theodosian line, and his vices were as conspicuous as his mental powers were contemptible.

VALENTINIANS. See GNOSTICS, vol. viii., p. 52.

VALENTINOIS, Duchess of. See DIANA OF POITIERS.

VALERIAN (Lat. *valere*, to be well), a genus of monopetalous plants, *valeriana*, which with a few others makes up the family *valerianaceæ*. On account of a similarity in the structure of the individual flowers, the family in a systematic arrangement stands near *compositæ*, though they are not, as in that order, collected into a head, but in a corymb or cyme. In valerian the inferior ovary has one fertile one-ovuled cell, and two empty or abortive ones; the adherent calyx has its limb developed as several plumose bristles, which are rolled inward in flower, but as the fruit matures expand as a pappus; the tube of the corolla is usually gibbous, or swollen at one side near the base, and the limb has five nearly regular lobes; stamens three. There are about 150 species, mostly perennial herbs, with thickened roots, which are strong-smelling when dry, entire or divided leaves, and white or rose-colored flowers; they are widely distributed, but most abundant in mountainous regions; three are natives of the northern states, but rather rare and local. The most important of these is the edible valerian (*V. edulis*), so called because its large spindle-shaped root, sometimes a foot long, is roasted and eaten by the western Indians; its leaves are fringed-ciliate, and its stem, 1 to 4 ft. high, bears an interrupted panicle of whitish flowers. *V. pauciflora* is found from Pennsylvania and Ohio southward, while the first named and *V. sylvestris*, our third native species, are northern and western. The best known of all the species is *V. officinalis*, the root of which is the medicinal valerian, and the plant is quite common in gardens, where it is cultivated for the fragrance of its flowers; the leaves have from 11 to 21 oblong, cut-toothed, somewhat downy leaflets; the stem, 2 to 3 ft. high, bears a broad, terminal corymb of small white flowers, often tinged with pink, with an odor like that of heliotrope, on which account it is often called garden heliotrope. A closely related species, with less divided leaves, *V. phu*, is also cultivated. The medicinal species is found all over Europe, from Spain to Iceland, and in northern Asia, and is cultivated in England and sparingly in this country for its roots; it has an erect rootstock, to which are attached numerous rootlets 3 to 4 in. long; the rootstock is usually cut to facilitate drying. When freshly dug the root has no characteristic odor, but when dry it has a peculiar terebinthine or camphorous odor, and a bitterish aromatic taste. The chemical composition of the root is somewhat complex; when fresh it gives from ½ to 2 per cent. of volatile oil; the dried root yields less oil, with valerianic acid, which results from the oxidation of the oil during the drying, and a resinous substance; the changes which take place in the root, and the different products, have not been well studied. Valerian has long been used in medicine, and it is supposed that the *phu* mentioned by Dioscorides and other ancient writers was this plant. In the 16th century it was used in England to flavor soups and pottages, and the roots, though the odor is now disagreeable to most persons, were placed among clothes as a perfume. Cats are exceedingly fond of the odor; a piece of the root seems to intoxicate them. Valerian belongs to that class of nervous stimulants known as antispasmodics, and in hysteria and other affections of women it is used in both domestic and regular practice; it is administered in the form of infusion, tincture, and fluid extract.—The valerian family includes *centranthus*, of which several species are cultivated as ornamental plants, and *fedia*, of which *F. olitoria* is cultivated, and is known as corn salad.



Valerian (Valeriana officinalis).

VALERIAN (PUBLIUS LICINIUS VALERIANUS), a Roman emperor, who reigned from A. D. 253 to 260. He was descended from a noble Roman family, rose to the highest honors of the state, and was fixed upon by the emperor Decius, who in 251 had determined to revive the censorship, as the fittest person for that post; but he was saved from discharging its unenviable duties by the death of the emperor. His successor Gallus sent Valerian to bring the legions of Gaul and Germany to aid in quelling the rebellion of Æmilianus; but before his arrival Gallus had been slain. Æmilianus shared the same fate, and Valerian was called to the throne. He immediately associated with himself in the empire his son Gallienus. His whole reign was spent in resisting the assaults of the Franks, Alemanni, and Goths, and in the East of the Persians. Leaving the defence of the West to his son and to his lieutenant, the emperor marched against the Persian monarch, but was taken prisoner with his army, and the victory of Sapor was followed by the capture of Antioch and the overrunning of Asia Minor. His son usurped the throne, gave himself up to debauchery, and allowed the empire to be overrun by the barbarians. (See GALLIENUS.) Valerian died in captivity. The accounts of his reign are contradictory, and the chronology is uncertain.

VALERIANIC ACID, or **Valeric Acid,** an acid which bears the same relation to amylic alcohol that acetic acid does to ethylic or common alcohol. It was first obtained by Chevreul in 1817 from the fat of a dolphin, *delphinum phocæna*, and was called delphinic or phocenic acid. In 1830 Grote obtained from the essential oil of valerian an acid which he called valerianic acid, and which was shown by Trommsdorff and Ettling to be identical with Chevreul's delphinic acid. It was afterward produced by oxidation of amylic alcohol by Dumas and Stas, who pointed out its relation to this body and showed its composition to be $C_5H_{10}O_2$. It is found in many vegetables, as valerian, angelica, and several other roots, in the fruit and bark of *viburnum opulus*, in the bark of the elder, and in many composite plants. It is also produced by the oxidation of fats and the putrefaction of albuminous substances. It is prepared from amylic alcohol by adding to it twice its weight of strong sulphuric acid, and passing this slowly into a solution of bichromate of potash, and, after heating for some time in a flask, distilling and saturating the distillate with sodium carbonate. Sodium valerianate is produced, which is treated with sulphuric acid and distilled. It is a colorless, mobile oil, having a sour, burning taste, and an odor resembling oil of valerian combined with rancid cheese. Its specific gravity at 61° is 0·937, according to Dumas and Stas; and its index of refraction, according to Delffs, is 1·3952. It affects the plane of polarization of light according as it has been prepared from active or inactive amylic alcohol. The active modification produces a rotation of +43° in a tube 50 centimetres long. It boils at 347° F., and remains liquid and transparent at 5°. It dissolves in 30 parts of water at 53·6°, and in all proportions with alcohol and ether. Its vapor passed through a red-hot tube is converted into carbonic anhydride, carbonic oxide, ethylene, tritylene, and tetrylene, with sometimes light carburetted hydrogen. It is monobasic, forming neutral salts having the general formula $C_5H_9MO_2$, and a few acid and basic salts.—The valerianates are unctuous to the touch, inodorous when dry, but with a pungent strong smell of valerianic acid when moist, which is heightened by warmth. Valerianate of ammonia is prepared by passing ammoniacal gas through valerianic acid. It crystallizes in white, pearly, four-sided, tabular crystals, having an offensive odor. It is often formed in the putrefaction of organic bodies, and is a frequent constituent of rancid cheese. It was introduced as a therapeutic agent by M. Déclat of Paris for the treatment of neuralgia; it may be given in doses of one or two grains of the salt dissolved in water. Valerianate of bismuth has been used successfully in neuralgia and painful affections of the stomach, in doses of from one to two grains. Valerianate of iron is often used in hysterical affections complicated with chlorosis, in doses of one grain, repeated several times a day. Valerianate of quinia is prepared by dissolving the alkaloid in valerianic acid and evaporating the solution below 120° F. It is a colorless salt, crystallizing in rhombohedral plates having a bitter taste and a powerful, repulsive odor, soluble in 110 parts of cold and 40 parts of boiling water. By continuing the boiling, the salt is decomposed with evolution of valerianic acid. It is given in cases of debility and nervous affections, in doses of one or two grains several times a day. Valerianate of atropia, the active principle of *atropa belladonna*, has been employed with benefit in epilepsy and other nervous diseases, in very minute doses. Valerianate of zinc is prepared by the action of valerianate of soda on sulphate of zinc. It possesses decided antispasmodic properties, and has been used with advantage by Dr. Namias of Venice, Italy, in nervous affections attended with palpitation of the heart, and by Dr. François Devay of Lyons, France, in epilepsy and in nervous affections accompanying chlorosis. The valerianic ethers, or valerianates of the alcohol radicals, are prepared by distilling valerianate of sodium with sulphuric acid and the corresponding alcohols. Amylic valerianate dissolved in six or eight parts of alcohol forms a flavoring liquid known as apple essence.

VALERIUS CORVUS, Marcus, a Roman general, born about 371 B. C., died about 271. In 349, being tribune under L. Camillus in his campaign against the Gauls, he accepted the challenge of a gigantic barbarian to single combat, and killed his antagonist, as the story goes, with the assistance of a raven, which perched upon Valerius's helmet, and as often as he advanced upon his foe flew at the Gaul's face. A general battle ensued, in which the Romans were completely victorious. From this circumstance Valerius is said to have derived his surname of Corvus. He was made consul in 348 and five times subsequently. In 343 he gained two brilliant victories over the Samnites at Mount Gaurus and at Suessula. In 342 he was appointed dictator in consequence of a mutiny in the army, which he quelled by his personal popularity. He was dictator again in 301, when he defeated the Marsi and Etruscans. The last 28 years of his life were passed in retirement. He held curule dignities 21 times, and repeatedly enjoyed the honors of a triumph.

VALERIUS FLACCUS, Caius, a Latin poet, born in Padua, flourished in the time of Vespasian, and died about A. D. 88. Nothing is known of his life, and his only work now extant is the unfinished heroic poem called the *Argonautica*, in which he narrates the adventures of Jason and his companions. His poem was discovered in 1416 in the monastery of St. Gall, and was first published in 1472. The best edition is Theil's (Halle, 1863). It has been translated into English verse by Nicholas Whyte (1565), and the first book by Thomas Noble (1809).

VALERIUS MAXIMUS, a Roman author, who flourished during the reign of Tiberius. Nothing is known of his life except that he accompanied Sextus Pompius, the friend of Ovid, into Asia. His name is appended to a collection of historical anecdotes under the title of *Factorum et Dictorum Memorabilium Libri IX.* The compilation embraces a large variety of subjects, and as a historical authority is of some value. His diction is very ornate, but often incorrect and obscure. He was one of the favorite authors of his time, and the frequent copying of his works has undoubtedly been very injurious to the text. His books were also a favorite study in the middle ages, and were frequently imitated (as by Saxo Grammaticus), abridged, and translated. Epitomes of his works by Julius Paris and Januarius Nepotianus are extant. The best edition with critical apparatus is Halm's (Leipsic, 1865). It was translated into English by W. Speed (London, 1678).

VALERIUS PUBLICOLA. See PUBLICOLA.

VALETTA, or **La Valetta,** a seaport town, capital of the island of Malta, on the N. E. coast, in lat. 35° 54′ N., lon. 14° 31′ E.; pop. about 60,000. It occupies an elevated peninsula between two harbors, the one on the east, called the Great harbor, extending about 2 m. inland. Five forts command the approach by sea, and five lines of fortifications, mounting 1,000 guns, and hornwork, extend across the isthmus. The ground upon which it stands is very uneven, and the streets are connected by flights of steps. The cathedral was built in 1580, and is exceedingly interesting for its numerous monuments in marble and bronze, paintings, and curious relics. The keys of Jerusalem, Acre, and Rhodes are deposited in it. There are 19 other churches. The palace of the grand master of the knights of Malta is now the governor's residence; it contains a corridor hung with the portraits of the knights, an armory with many kinds of ancient armor, and a library and museum adjoining. The university was founded in 1838, and has faculties of divinity, law, medicine, and arts. There are naval, military, and civil hospitals. The other buildings most worthy of notice are the exchange, theatre, several *auberges* or separate palaces of the knights, and the house of industry. A great aqueduct supplied Valetta with water from Città Vecchia, 8 m. distant. The botanic garden is in the suburb of Floriana. The burial grounds have been formed out of the bastions of the fortifications. The opera house, erected at great cost a few years before, was destroyed by fire

Valetta.

in May, 1873. (For the commerce and history of the city, see MALTA, and VALETTE.)

VALETTE, Jean Parisot de La, a grand master of the knights of Malta, born in 1494, died in Malta, Aug. 21, 1568. He belonged to an eminent family of Toulouse, passed through every grade of his order to lieutenant general, and was in 1557 unanimously chosen grand master as successor of Claude de la Langle. The assistance which he rendered in the wars against the Turks, and the rapid growth of the order under his administration, induced Solyman the Magnificent to fit out an expedition for the reduction of Malta; and on May 18, 1565, 180 Turkish vessels of war, with 30,000 troops on board, cast anchor in the gulf of Mugiarro. La Valette had constructed new fortifications at the N. E. extremity of the peninsula now occupied by the city of Valetta, but his garrison consisted of only 700 knights and 8,500 soldiers, including the inhabitants who had been armed for the occasion; yet with these he withstood one of the most terrific sieges on record until Sept. 8, when, on the arrival of the viceroy of Naples with 8,000 men for his assistance, the Turks took to their ships. They disembarked again, but were defeated with great slaughter and fled in disorder. Their loss during the siege is said to have been 30,000 (they had several times been reënforced); while the knights, on the departure of the Turkish fleet, had barely 600 left of all their combatants. La Valette rebuilt the fortifications, and founded the town of Valetta, to which he removed the residence of the knights from Città Vecchia.

VALHALLA. See MYTHOLOGY, vol. xii., p. 120.

VALLA, Lorenzo, an Italian scholar, born in Rome about 1410, died there or in Naples about 1460. He was ordained a priest in 1431, taught rhetoric in Pavia and other cities, and in 1435 went to Naples, where he gained the friendship of Alfonso I., and accompanied him in his wars and voyages. In 1443 he returned to Rome, where he incurred the hostility of the cardinals and Pope Eugenius IV. by attacking the authenticity of the instrument known as the "donation of Constantine," upon which the popes in great part based their claims to temporal sovereignty. Valla fled to Naples and opened a school, but became involved in theological controversies, and only escaped the inquisition through the protection of the king. He was subsequently received in Rome by Pope Nicholas V., to whom he presented a portion of the Homeric poems translated for the first time into Latin, and his translation of Thucydides, for which he received 500 crowns and the offices of apostolical secretary and canon of St. John Lateran. His works, including *Elegantiæ Linguæ Latinæ*, in six books, were collected in 3 vols. fol. (Basel, 1543).—See Vahlen's *Lorenzo Valla* (Vienna, 1864).

VALLADOLID. **I.** A N. W. province of Spain, in Old Castile (by some included in the kingdom of Leon), bordering on Leon, Palencia, Burgos, Segovia, Ávila, Salamanca, and Zamora; area, 3,043 sq. m.; pop. in 1870, 242,384. The surface, though elevated, is generally level, and the soil is sandy. The principal rivers are the Douro and its affluents the Duraton, Eresma, and Pisuerga. The province produces grain, red and white wines, flax, hemp, madder, and timber. There are excellent pastures, and numerous horses, cattle, sheep, and mules are raised. Paper, earthenware, and various fabrics of hemp and flax are manufactured. **II.** A city, capital of the province, in an extensive plain on the left bank of the Pisuerga, at the terminus of the canal of Castile, 100 m. N. W. of Madrid; pop. about 50,000. It is irregularly built, but contains some fine streets and squares. The cathedral, begun by Philip II., has never been completed; it has a Doric façade, with an arch over the principal entrance 50 ft. by 24. There are many other churches, convents, and nunneries, of which the churches of Santa Maria la Antigua, San Martin, and San Benito are fine specimens of architecture. The university, for students of law and of medicine, was founded by Alfonso XI. in 1346. There are several colleges, a museum containing the statues, pictures, and other works of art which were removed from the suppressed convents, a royal palace, a theatre, a lyceum, and a public library. Silks, lace, paper, woollens, and earthenware are manufactured, and there is a large trade in corn. —Valladolid was called Belad-Walid by the Moors, from whom it was taken by Ordoño II. of Leon in 920. It was the capital of Castile and of Spain from the beginning of the 15th century till 1560, when Philip II. removed the court to Madrid. Columbus died in Valladolid.

VALLADOLID, a city of Mexico. See MORELIA.

VALLADOLID, a town of Mexico, capital of a department of the same name in the state of Yucatan, 90 m. E. S. E. of Mérida; pop. about 15,000. The streets are well laid out and clean, and the houses are generally one story high with flat roofs. There are several churches, a town house, and an aqueduct. The climate is healthful, and the town is much resorted to by invalids. Cotton is manufactured.

VALLADOLID, a town of Honduras. See COMAYAGUA.

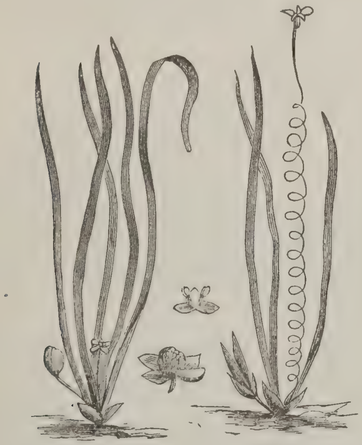
VALLAURI, Tommaso, an Italian philologist, born at Chiusa di Cuneo, Jan. 23, 1805. He early became professor of rhetoric in the university of Turin, and afterward of Greek and Latin eloquence; and he ranks as one of the best Latinists of Italy. His works include *Historia Critica Literarum* (1849; 7th ed., 1868); *Trinumus* (1855); *Menæchmi* (1859); *Novelle* (4th ed., 1868); editions of Ausonius Popma's *De Differentiis Verborum* (1852), and of the *Aulularia* (1853) and *Miles Gloriosus* (1854) of Plautus; Latin-Italian dictionaries; and books on history and literature.

VALLE, Pietro della, an Italian traveller, surnamed Il Pellegrino, born in Rome, April 2, 1586, died there, April 20, 1652. In June, 1614, he embarked from Venice in the habit of a pilgrim. He went first to Constantinople, remained a year, then visited Egypt and the Holy Land, and at Bagdad married a Nestorian woman. He next journeyed over Mesopotamia, and finally went to Ispahan and engaged in the war between Persia and Turkey. His wife having died, he embalmed her body and took it home with him, travelling through India, and reaching Rome in 1626. To Pope Urban VIII., who made him honorary chamberlain, he presented a short account of Georgia, in order to induce him to send missionaries to that country. Not long afterward he married a Georgian, whom he had brought with him from the East. His travels, written in the form of letters, were published at Rome in 1650–'53 in 4 vols. (English translation, fol., London, 1665). Several other works were composed by him, many of which were never published. His narratives, in spite of their prolixity, are very accurate.

VALLEY, a central county of Nebraska, intersected by Loup fork and its N. branch; area, 576 sq. m.; pop. in 1875, 287. The surface is rolling, and consists chiefly of productive prairies.

VALLIÈRE, Mlle. de La. See LA VALLIÈRE.

VALLISNERIA, a genus of endogenous aquatic plants, named in honor of Antonio Vallisnieri. It belongs to a small family, the *hydrocharidaceæ*, all water or marsh plants, and consists of but two species, one exclusively Australian, and the other, *V. spiralis*, found in the fresh waters of most countries, especially the warmer ones, and in nearly all parts of the United States, where it is known as tape grass and eel grass, though quite distinct from the eel grass of salt waters (*zostera*). The stem or rootstock lies prostrate in the mud; from this proceed the tape-like leaves, 1 to 2 ft. long, 2 to 5 lines wide, and minutely serrulate on the edges; these are dark green and entirely submerged. The flowers are diœcious; those of the staminate plant are several in a small cluster, surrounded by a three-valved spathe and borne upon a very short scape which rises at the base of the leaves. The fertile flowers are solitary, with a long ovary, at the apex of which are three small petals and three large two-lobed stigmas; each flower is borne upon a slender spirally coiled scape, which is from 2 to 4 ft. long, according to the depth of the water. At flowering time these female or pistillate flowers rise by means of their long flexible stems to the surface of the water, where they are quite beyond the reach of the staminate or male flowers, which are confined at the bottom upon a stem only about an inch long. The male flowers, as they mature, spontaneously break away from their short stems and rise to the surface, where they expand and float about, shedding their pollen upon the stigmas of the female flowers; after fertilization takes place, the long stem to the pistillate flower shortens its coils and carries the impregnated ovary to the bottom again, where it ripens into a many-seeded berry from half an inch to two inches long. The leaves of *Vallisneria* afford a most interesting object for the microscope; the tissues being very thin and transparent, they allow the contents of the cells to be distinctly seen, and these are found to be in constant motion, the contents of each cell moving independently of those of the others. The plant is very abundant in some waters; there are localities upon the Hudson where at certain seasons it is difficult to force a boat through it. It is also abundant on the waters of Chesapeake bay, where it is called by the singular misnomer of wild celery; the rootstocks and their buds are the favorite food of the canvas-back duck, a fact recognized in its specific name, *fuligula Vallisneria.*



Vallisneria spiralis—Staminate and Pistillate.

VALLISNIERI, Antonio, an Italian naturalist, born at Tresilico, Modena, May 3,1661, died in Padua, Jan. 18, 1730. He studied medicine at Bologna, and about 1688 began practice in Reggio. In 1700 he became professor at Padua, where he excited opposition by his attempted reforms in medicine. He was indefatigable in his efforts to advance the knowledge of natural history, and in his researches on generation, and opposed the doctrine of spontaneous generation. His complete works were published at Venice in 1733 (3 vols. fol.).

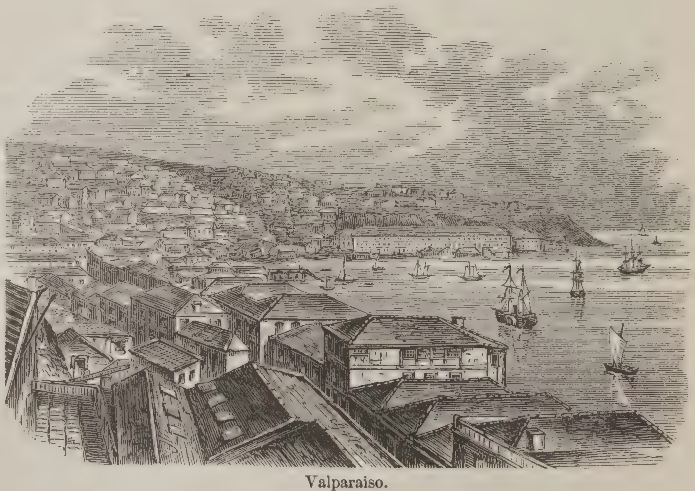
VALLOMBROSA (shady valley), an abbey in a valley of the Apennines about 15 m. E. of Florence. It was founded by St. Giovanni Gualberto about 1038, under the rule of St. Benedict, and the institution was approved by Pope Alexander II. in 1070. The original purpose of the founder was to establish separate hermitages, but the cenobitic or community life soon prevailed, and the Vallombrosians are now recognized as a branch of the reformed Benedictines. In 1500 they exchanged their gray habit for a brown one, and in 1662, on their union with the Silvestrines, adopted a black dress. The present buildings were erected in 1637. The abbey was wealthy. It was suppressed in 1863; the monastery and church are now occupied by the royal school of forestry, opened in 1869.

VALMORE, Marceline Félicité Josèphe Desbordes, a French authoress, born in Douai about 1787, died in Paris, July 7, 1859. She was the daughter of M. Desbordes, a poor artist, and spent a part of her early life with her mother in Guadeloupe. On her return to France she appeared on the stage as a singer, and in 1817 she married the tragedian Valmore. Her works include *Recueil de poésies* (3 vols., 1829); *Les veillées des Antilles* (2 vols., 1830); *L'atelier d'un peintre* (2 vols., 1833); and *Le salon de Lady Betty* (2 vols., 1836).—See Sainte-Beuve, *Madame Desbordes-Valmore, sa vie et sa correspondance* (Paris, 1870; English translation by Harriet W. Preston, Boston, 1872).

VALOIS, House of, a younger branch of the Capetian dynasty, so called from the territory of Valois in Île de France, which occupied the throne of France 261 years, from the accession of Philip VI. in 1328 to the death of Henry III. in 1589 and the accession of Henry IV., the first of the Bourbons. (See PHILIP VI., and FRANCE.)

VALONIA. See OAK, vol. xii., p. 558.

VALPARAISO. I. A W. central and the smallest province of Chili, bounded N. by Aconcagua, E. and S. by Santiago, and W. by the Pacific; area, including the islands of Juan Fernandez, which belong to it, 1,670 sq. m.; pop. in 1875, 176,682. The surface is mountainous, and the soil, where not irrigated, is poor, excepting in some of the valleys, which are very fertile and produce excellent crops of the cereals, grasses, and fruits. Wine and brandy are made in considerable quantities. Mines of copper and silver are worked, but agriculture is the principal industry. It is divided into the departments of Valparaiso, Quillota, Limache, and Casablanca, named after their chief towns. The department of Valparaiso is divided into 24 subdelegations, of which the city comprises 20, the rural suburbs three, and the islands of Juan Fernandez one. **II.** A city, capital of the province, on a bay of the same name, in lat. 33° 1′ 56″ S., lon. 71° 41′ 45″ W., 70 m. N. W. of Santiago; pop. about 110,000. Back of the city is a high chain of hills, which nearly surround the bay, opening only toward the north. The older part of the city, called the port, extends along the shore at the base of the hills. It contains the principal public and commercial buildings. Beyond it is San Juan de Dios, which extends to the plaza de la Victoria, and beyond that is the Almendral, the most thickly populated quarter, where most of the retail business is done. Still further on is El Baron, on a hill of the same name, and next is La Cabritería, on the road leading to Quillota. The other principal quarters, named from the hills on which they are situated, are Cordillera, Santo Domingo, San Francisco, Carretas, Artillería, Toro, Arrayan, Alegre, and Concepcion. The last two contain the residences of most of the foreign merchants. The streets are generally narrow and irregular, excepting in the newer parts, where they are broad and laid out at right angles to each other. There are six plazas. Among the principal buildings are the government palace, the custom house and government warehouses, the post office, built in 1869, the exchange, the city hall, and two theatres, one of which, the Victoria, will seat 2,000 persons, and is remarkable for its interior decorations. Besides three parish churches, there are several others, of which the Franciscan, a Gothic edifice, is the finest; several chapels and oratorios, and three Protestant churches. Among the charitable institutions is the English, French, and United States hospital, attended by resident physicians. The city is lighted with gas, and has lines of horse cars and steam fire engines. Of the inhabitants of Valparaiso about 75,000 are natives, 15,000 Germans, 6,500 British, 3,750 French, 1,500 Italians, 250 Americans, and the remainder mostly natives of other South American states.—The bay is well sheltered excepting on the north, is capacious, and has plenty of water. It is defended by a chain of 15 forts, mostly built since 1866, mounting in the aggregate 142 guns. Its position gives it great com-



Valparaiso.

mercial advantages, and it is the chief port in the South Pacific. It is the headquarters of foreign men-of-war in the Pacific, and is connected with Panama and intermediate ports by an English and a Chilian line of steamers, and with Hamburg by a German line. It is connected with Santiago by railway. During the year ending Sept. 30, 1874, the port was entered by 1,585 vessels, of 973,090 aggregate tonnage. Of these 611 were British, 276 Chilian, 161 Nicaraguan, 103 German, 101 French, 99 Guatemalan, 87 American, 67 oriental, and 46 Italian. The total value of exports to the United States during that year was $1,041,697; of imports from the United States, $1,999,476.—Valparaiso was founded in 1544; taken by Drake in 1578, and again in 1596 by Hawkins's expedition; and sacked in 1600 by the Dutch corsair Oliver van Noort. It was nearly destroyed by earthquakes in 1730 and 1822. On March 31, 1866, it was bombarded by a Spanish squadron under Admiral Nuñez, and a large part of it ruined. (See CHILI.)

VALTELLINA (from the It. *Val Tellina;* Ger. *Veltellin* or *Veltlin*), a valley of Lombardy, in the province of Sondrio, separated by the Rhætian Alps from the Engadine, bounded N. by the Swiss canton of Grisons, N. E. by Tyrol, from which it is separated by the Ortler and the Stilfser Joch, S. by the provinces of Brescia, Bergamo, and Como, and W. by the lake of Como and the valley of Chiavenna. The valley of Valtellina proper is 45 m. long, and with its continuation, the valley of Bormio, 55 m. Together with the valley of Chiavenna it constitutes the province of Sondrio; and the three valleys are sometimes collectively called Valtellina. It is remarkable for fertility, the chief products being wine, grain, fruit, and cheese. The three valleys belonged in the latter part of the middle ages to the dukes of Milan. They became part of Grisons in 1512, and through the influence of France remained in possession of the Swiss despite the efforts of Austria during the thirty years' war to secure the territory. In 1797 Valtellina became part of the Cisalpine republic, and in 1804 of the French department of Adda. In 1814 it came under Austrian rule as part of Sondrio, and in 1859 under Italian rule. Besides Sondrio, the capital of the province, the most noted localities are Teglio, formerly the capital of Valtellina; Grossotto, where a fearful massacre of Protestants took place on July 19, 1620, known as the Valtellina massacre; and Morbegno, where the inquisition took up its headquarters after this episode, and which derived its name from the prevailing malaria.

VÁMBÉRY, Arminius, a Hungarian traveller, of Jewish parentage, born at Szerdahély, county of Presburg, in 1832. He was intended for a tailor, but studied at Presburg, Vienna, and Pesth, supporting himself in the intervals as a private teacher. He finally went in this capacity to Constantinople, where he familiarized himself with eastern languages. To acquire a knowledge of those of central Asia, he went in 1862 to Persia with the aid of the Pesth academy. In the disguise of a dervish he joined in 1863 Yarkand pilgrims returning from Mecca, and in that and the following year he explored parts of Turkistan, visiting the cities of Khiva, Bokhara, and Samarcand. On his return to Pesth he became oriental professor at the university, which post he still holds (1876). His works include a Turkish-German pocket dictionary (1858); "Travels in Central Asia" (1865); *Cagataische Sprachstudien* (1867), one of the first works written on the Turkish of the East, but the accuracy of which is contested; "Wanderings and Adventures in Persia" (1867), to which he added in 1868 "Sketches of Central Asia;" *Uigurische Sprachmonumente und das Kudatku-Bilik* (1870); *Magyar-török szóhasonlatok*, a comparison of Hungarian and Turkish words (1870); "History of Bokhara or Transoxiana, from the Earliest Period down to the Present" (1873); "Central Asia and the Anglo-Russian Frontier Question" (1874); and "The Islam in the Nineteenth Century" (1875). His principal works were translated by himself into English, and published simultaneously in English and German, and have been translated into other languages. Vámbéry is friendly to England, where his writings are very popular; but Russian and other authorities tax him with inaccuracies of statement, some of them going so far as to allege that he had never visited Samarcand and other places of which he gives elaborate descriptions. He has in press (1876) a work on the history, traditions, languages, and literatures of the various Turkish tribes in Asia and Europe.

VAMPIRE, in zoölogy. See BAT.

VAMPIRE, a fabulous creature of popular belief, especially in Greece, Hungary, Moravia, Silesia, Poland, and Russia. The ghouls of the Persians and Arabians, subjects of a like credulity, seem closely related to the fabled vampire, and may have suggested it. Vampires were described as persons who for a considerable time after death leave their tombs to disturb the living, usually their young relatives, sucking their blood, appearing to them, making strange noises, and often causing death. The fatal epidemics prevalent in the 17th and 18th centuries, and the sudden deaths or languor and exhaustion which marked their severity, fostered this superstition. Many bodies disinterred, being found undecayed and with liquid blood and fresh complexion, were for these reasons deemed undoubted vampires; and to prevent their fatal activities sharpened stakes were driven through them and their hearts and heads were severed and burned.

VAN. I. A town of Turkish Armenia, in the vilayet and 145 m. S. E. of the city of Erzerum, near the E. shore of Lake Van; pop. about 35,000. It is in a beautiful region of fruit trees and gardens. The streets are in a miserable condition, and there are no notable buildings excepting the palace of the local authorities, the mosques, and Armenian churches. A third chapel and a school were opened in 1874 by the American missionaries. Coarse cotton cloth is made and exported, and there are salt refineries. A rocky hill with a ruined citadel extends over one mile; inside the citadel are vast caves with cuneiform inscriptions and other relics referred to the days of Semiramis, who, according to tradition, laid out the city on a magnificent scale and resided there in summer; hence the Armenian name of Shamiramagerd, city of Semiramis. It took its present name from the Armenian king Van (371–351 B. C.), who embellished and extended the place. Under the real or nominal rule of the Macedonian and Syrian Greeks it became known as Iban. It was afterward the seat of the Armenian dynasty of the Arsacidæ, which, with intervals of Roman domination, reigned till A. D. 428, when the country was subjugated by the Persians. At the close of the 10th century Van flourished once more as the capital of the third Armenian kingdom of Vashburagan. The invasion of the Seljuk Turks in the 11th century ushered in a long series of calamities, and the extinction of the Armenian kingdom. The sanjak of Van comprises a large population of Armenians, Kurds, and Turkomans. **II.** A celebrated salt lake, the largest in Armenia, about 1,400 sq. m. in extent, and 5,400 ft. (according to Rawlinson) above the sea level. It is a triangular basin extending N. E. to S. W. over 80 m. between Arnis and Tadvan; greatest width, between Akhlat and Van, about 50 m. It is surrounded by high mountains, reaching in parts the level of perpetual snow, alternating with beautiful plains. The waters are of the deepest blue; the luxuriant vegetation along its banks is unsurpassed in that part of Asia. It has no outlet, but is less impregnated with salt than Lake Urumiah, receives several streams, and contains islets. Among the interesting towns on the lake shore is Akhlat, once the residence of Armenian kings, with a vast population.

VANADIUM, a metal, first recognized as distinct in 1801 by Del Rio, who found it in the brown lead ore (now known as vanadinite) of Zimapan in Mexico, and called it erythronium. But it was generally considered by chemists to be chromium, an opinion afterward adopted by Del Rio himself. In 1830 Sefström found the iron made from the magnetic ore of Taberg in Sweden, as well as the cinder produced in its conversion, to contain a peculiar metal, which he called vanadium, from Vanadis, one of the names of the Scandinavian goddess Freyja; and the Zimapan lead ore was afterward found by Wöhler to contain the same metal. It has also been discovered in the iron slag of Staffordshire, and recently by Roscoe in larger quantity in the copper-bearing beds at Alderley Edge and Mottram St. Andrews, Cheshire, by Dr. Bolton in pitchblende, by Dr. Hayes in many rocks, and by Böttger in pea iron ores. The metal is obtained by prolonged ignition of the dichloride in a stream of pure dry hydrogen gas. It is a grayish white powder, which has the appearance under the microscope of a silver-white crystalline mass. It does not tarnish in the air, burns with brilliant scintillations when thrown into a flame, burns vividly when quickly heated in oxygen, forming a pentoxide, and takes fire in a current of chlorine gas, forming a tetrachloride. It is insoluble in hydrochloric acid. It has until recently been regarded as a hexad metal, analogous to tungsten; but Roscoe has shown, by a comparison based upon the composition of the oxides and oxychlorides, and upon the isomorphism of the vanadates with phosphates, that it is a pentad, belonging to the arsenic and phosphorus group. Vanadium forms five oxides: V_2O, V_2O_2, V_2O_3, V_2O_4, and V_2O_5; compounds analogous to the oxides of nitrogen, V_2O_5 being called vanadic anhydride, and sometimes pentoxide of vanadium. The monoxide, V_2O, is a brown substance formed by prolonged exposure of the metal to the air at ordinary temperatures, or more quickly at a dull red heat. The dioxide, V_2O_2, is produced by continued heating of the monoxide. The trioxide, V_2O_3, is formed by igniting the pentoxide, V_2O_5, in hydrogen gas, or in a crucible lined with charcoal. When exposed to warm air it absorbs oxygen, glows with a dull red light, and passes again into pentoxide. Vanadious oxide or anhydride, or vanadium tetroxide, V_2O_4, is formed by further oxidation of the dioxide or trioxide, or by partial reduction of the pentoxide. It forms with acids vanadious salts, which have a bright blue color. Vanadium pentoxide, or vanadic anhydride, may be prepared from the native lead vanadate. The mineral is dissolved in nitric acid, and the lead and arsenic precipitated by sulphuretted hydrogen, which also reduces the vanadium pentoxide to tetroxide. The blue filtered solution is then evaporated to dryness, which reconverts the tetroxide to pentoxide. It is then digested in aqua ammonia, which dissolves the pentoxide. A lump of sal ammoniac (chloride of ammonium) is put into the solution, and as the salt dissolves ammonium vanadate is precipitated, being only very slightly soluble in a saturated solution of the chloride of ammonium. A temperature below redness expels the ammonium. It is a reddish yellow powder, which dissolves in 1,000 parts of water, forming a light yellow solution. With stronger acids it forms vanadic salts, but it unites with bases more readily than with acids, forming salts called vanadates of various constitution, as orthovanadates, having the general formula $(3MO),V_2O_5$; pyrovanadates, $(3MO),V_2O_5$; metavanadates, MO,V_2O_5, analogous to metaphosphates; divanadates, $MO,2V_2O_5$; and trivanadates, $MO,3V_2O_5$. In the United States the principal localities of vanadium minerals are at the Wheatley mine, Phœnixville, Pa., where several vanadates of lead occur, and at the Cliff mine, Lake Superior, where a chocolate-colored mineral is found containing vanadic acid. Vanadic acid is used in the manufacture of a permanent black ink.

VANAYL DE YONGH. See SAINT-ELME.

VANBRUGH, Sir **John,** an English dramatist, born probably in London in 1666, died there, March 26, 1726. He was of Flemish extraction, and received a liberal education, which was completed in France. He entered the army as an ensign, attained the rank of captain, and afterward became an architect. In 1695 he was appointed secretary to the commission for endowing Greenwich hospital, and two years later produced at Drury Lane theatre his first play, "The Relapse," which was very successful. "The Provoked Wife" (1697) had if possible a greater run; and in the next year the author, alarmed at the charges of indecency and profanity brought against him in Jeremy Collier's "Short View of the Immorality and Profaneness of the English Stage," presented the public with a moral lecture, in the form of a comedy entitled "Æsop." An adaptation of Fletcher's "Pilgrim," produced in 1700, was well received. In 1702 he made his first architectural design of celebrity, that of Castle Howard in Yorkshire, the seat of the earl of Carlisle. His next enterprise was the construction of a large theatre in the Haymarket, which he undertook to manage in conjunction with Congreve. The building was found to be incurably defective in acoustic properties, and Vanbrugh, after producing with indifferent success "Confederacy" (1705), and adaptations of three of Molière's comedies, retired from the enterprise, and devoted himself to the structure of Blenheim, voted by parliament to the duke of Marlborough. Before the completion of the work he became involved in a quarrel with the duchess, who after the duke's decease dismissed the architect and refused to pay him £2,000 which he had advanced to the workmen. By the aid of Sir Robert Walpole he finally got the money. Vanbrugh erected other buildings of less note, was knighted and made comptroller of the royal works in 1714, and in 1716 surveyor of the works at Greenwich hospital. He left an unfinished comedy, "The Journey to London," which was completed by Colley Cibber. His plays are smoothly written, and present amusing pictures of contemporary manners, but their grossness has gradually banished them from the stage. The best recent edition is that of Moxon (8vo, London, 1849, containing also the works of Congreve, Wycherly, and Farquhar), with a biographical notice by Leigh Hunt.

VAN BUREN, the name of four counties in the United States. **I.** A central county of Arkansas, intersected by Little Red river; area, 1,260 sq. m.; pop. in 1870, 5,107, of whom 119 were colored. The surface is undulating and the soil fertile. There is a great abundance of choice timber. The chief productions in 1870 were 165,710 bushels of Indian corn, 11,116 of oats, 6,199 of Irish and 6,104 of sweet potatoes, 52,985 lbs. of butter, and 7,264 of tobacco. There were 1,029 horses, 1,416 milch cows, 3,430 other cattle, 2,574 sheep, and 11,559 swine. Capital, Clinton. **II.** A central county of Tennessee, drained by the Caney fork of Cumberland river; area, 350 sq. m.; pop. in 1870, 2,725, of whom 239 were colored. The surface is generally mountainous and the soil tolerably fertile. Bituminous coal is abundant. The chief productions in 1870 were 14,002 bushels of wheat, 104,033 of Indian corn, 4,456 of oats, 5,095 of Irish and 4,216 of sweet potatoes, 32,788 lbs. of butter, 6,006 of wool, and 9,858 of tobacco. There were 718 horses, 766 milch cows, 1,467 other cattle, 3,247 sheep, and 8,584 swine. Capital, Spencer. **III.** A S. W. county of Michigan, bordering on Lake Michigan, and drained by several streams; area, 633 sq. m.; pop. in 1874, 29,156. The surface is generally level and the soil fertile. A large portion of the county is covered with forests of valuable timber. It is intersected by the Michigan Central railroad and South Haven division, and by the Chicago and Michigan Lake Shore line. The chief productions in 1870 were 387,658 bushels of wheat, 572,578 of Indian corn, 159,835 of oats, 304,465 of potatoes, 646,998 lbs. of butter, 24,111 of cheese, 121,106 of wool, and 26,615 tons of hay. There were 6,271 horses, 5,702 milch cows, 6,857 other cattle, 32,955 sheep, and 13,294 swine; 2 manufactories of carriages and wagons, 10 of pig iron, 6 of iron castings, 8 tanneries, 5 currying establishments, 8 flour mills, 53 saw mills, and 2 wood turning and carving establishments. Capital, Pawpaw. **IV.** A S. E. county of Iowa, bordering on Missouri and intersected by Des Moines and Fox rivers; area, 468 sq. m.; pop. in 1870, 17,672. The surface is level, consisting of prairie and timber land, and the soil is highly fertile. Bituminous coal abounds. It is intersected by the Des Moines Valley railroad. The Des Moines river is navigable for steamboats a portion of the year. The chief productions in 1870 were 231,827 bushels of wheat, 41,205 of rye, 906,874 of Indian corn, 255,820 of oats, 73,322 of potatoes, 443,586 lbs. of butter, 129,303 of wool, and 22,948 tons of hay. There were 7,137 horses, 5,850 milch cows, 8,996 other cattle, 38,112 sheep, and 25,866 swine; 1 manufactory of agricultural implements, 11 of carriages and wagons, 1 of paper, 3 of stone and earthenware, 4 woollen mills, and 6 flour mills. Capital, Keosauqua.

VAN BUREN. I. Martin, the eighth president of the United States, born at Kinderhook, N. Y., Dec. 5, 1782, died there, July 24, 1862. He began the study of law at the age of 14, and passed the last year of his studies in the office of W. P. Van Ness in New York. At 18 he was a delegate in a nominating convention of the republican (afterward called the democratic) party. In 1808 he was appointed surrogate of Columbia co. In 1812 he was elected to the senate of the state, and in that body voted for electors pledged to support De Witt Clinton for president of the United States. From 1815 to 1819 he was attorney general of the state, and in 1816 was again a member of the senate, the two offices being held together. In 1818 Mr. Van Buren set on foot a new organization of the democratic party in the state, and became the ruling spirit of a coterie of able politicians, known as the Albany regency, among whom B. F. Butler, W. L. Marcy, and Edwin Croswell were afterward prominent, who held the political control of the state uninterruptedly for more than 20 years. In 1821 Van Buren was chosen to the United States senate, and was elected a member of the convention to revise the state constitution. In the latter body he advocated an extension of the elective franchise, but opposed universal suffrage, as also the plan of appointing justices of the peace by popular election. He voted against depriving colored citizens of the franchise, but supported the proposal to require of them a freehold qualification of $250. In 1827 he was reëlected United States senator, but resigned that office on being chosen governor of New York in 1828. As governor he proposed the safety fund banking system adopted by the legislature in 1829. In March, 1829, he became secretary of state in the administration of President Jackson, but resigned on April 7, 1831. He was appointed minister to England, and arrived in that country in September; but his nomination to the office, submitted to the senate in December, was rejected, on the ground that while secretary of state Mr. Van Buren had instructed the United States minister to England to beg from that country as a favor certain concessions in regard to trade with her colonies in the West Indies, which he should have demanded as a right; and that he had carried our domestic party contests and their results into foreign diplomatic negotiations. This event was followed on May 22, 1832, by the nomination of Mr. Van Buren for the vice presidency by the same democratic national convention which nominated Gen. Jackson for reëlection to the presidency; and in the subsequent election Mr. Van Buren received the electoral votes of all the states which voted for Gen. Jackson, with the exception of Pennsylvania. The democratic national convention which met at Baltimore on May 20, 1835, unanimously nominated him for president. The election in November, 1836, resulted in giving him 170 electoral votes out of 283, 73 being cast for his principal antagonist, Gen. W. H. Harrison, 26 for Hugh J. White, and 14 for Daniel Webster. He was inaugurated March 4, 1837. The country, for some time a prey to pecuniary excitements and embarrassments, was now involved in a crisis of unprecedented severity. Commerce and manufactures were prostrate; hundreds of wealthy mercantile houses in every quarter were bankrupt; imposing public meetings attributed these disasters to the policy of the government; and two months after the president's inauguration the crash was consummated by the universal suspension of specie payments by the banks. On May 15 he summoned an extraordinary session of congress to meet the following September. The president in his special message advised that a bankrupt law for banking and other corporations should be enacted; and that the approaching deficit in the treasury be made good by withholding from the states the fourth and last installment of a previous large surplus ordered to be deposited with them by act of June 23, 1836, and by the temporary issue of $6,000,000 of treasury notes. He also recommended the adoption of what was called the independent treasury system, which was passed in the senate, but was laid on the table in the other house. The payment of the fourth installment to the states was postponed, and the emission of $10,000,000 of treasury notes was authorized. The independent treasury, again recommended in the president's annual message in December, was again rejected by the house of representatives, after it had been passed by the senate. Another presidential measure was more fortunate, a so-called preëmption law being enacted, giving settlers on public lands the right to buy them in preference to other persons. An insurrectionary movement begun in Canada in the latter part of 1837 having found aid and sympathy within our borders, Mr. Van Buren issued two proclamations, enjoining all citizens to refrain from violating the laws and the treaties of the country; and he sent a military force to the frontier under Gen. Scott to preserve the peace there. The closing session of the 25th congress witnessed the temporary stoppage in the house of representatives of the agitation of slavery. Mr. Slade of Vermont introduced the subject in a long and elaborate anti-slavery speech, whereupon the southern members withdrew for separate deliberation, and Mr. Rhett of South Carolina proposed to declare that it was expedient that the Union should be dissolved; but on motion of Mr. Patten of Virginia it was determined by the house that for the future all petitions or other papers touching slavery should be laid on the table without being debated, printed, read, or referred. For this resolution the friends of the president unanimously voted, as did many of his opponents. Van Buren's third annual message, in December, 1839, was largely occupied with financial discussions, and especially with the argument for the divorce of the government from the banks, and for the exclusive "receipt and payment of gold and silver in all public transactions;" that is to say, for the independent treasury. This measure, by which his administration is especially distinguished, became a law on June 30, 1840.—The canvass preliminary to the presidential election of 1840 was begun uncommonly early and with unwonted energy by the opposition. The whig national convention on Dec. 4, 1839, nominated for president William Henry Harrison, and for vice president John Tyler. On the democratic side Mr. Van Buren had no competitor, and he was definitively made the candidate of his party by its national convention on May 5, 1840. Never in the political history of the United States was a canvass conducted amid such absorbing public excitement. The financial distress which had existed more or less oppressively since Mr. Van Buren's inauguration was a standing text for the opposition journals and for the orators who assailed him at monster meetings in every part of the country. Charges of extravagance, of corruption, of indifference to the welfare of the laboring classes, were freely brought against the democratic candidate; while the enthusiasm of the supporters of Harrison was inflamed by log cabins emblematic of his popular origin and habits, by songs, by processions, by assemblages counting tens and hundreds of thousands. The result was the discomfiture of the democrats in every state except Alabama, Arkansas, Illinois, Missouri, New Hampshire, Virginia, and South Carolina. Mr. Van Buren received only 60 electoral votes, while Gen. Harrison had 234; and yet so universal was the participation in the election, that the number of popular suffrages cast for the former was now 1,128,702, or over 367,000 more than had sufficed to secure his return four years previously. His last annual message set forth anew the benefits of the independent treasury system; announced, not without a natural movement of satisfaction, that the country was without either a national debt or a national bank; and concluded with advising the enactment of more stringent laws for the breaking up of the African slave trade.—In 1844 Mr. Van Buren's friends once more urged his nomination for the presidency by the democratic national convention at Baltimore; but he was rejected there on account of his opposition to the annexation of Texas to the Union, avowed in a public letter to a citizen of the state of Mississippi who had called for his opinion on that question. Though a majority of the delegates in the convention were pledged to support him, a rule fatal to this purpose was adopted making the votes of two thirds of the whole number necessary to the choice of a candidate. For several ballots he led all the competitors, when his name was withdrawn from the contest, and on the ninth ballot Mr. Polk was nominated. In 1848, when the democrats had nominated Gen. Cass, and avowed their readiness to tolerate slavery in the new territories lately acquired from Mexico, Mr. Van Buren and his adherents, adopting the name of the free democracy, at once began to discuss in public that new aspect of the slavery question. They held a convention at Utica on June 22, which nominated Mr. Van Buren for president and Henry Dodge of Wisconsin for vice president. Mr. Dodge declined the nomination, and at a great convention in Buffalo on Aug. 9, Charles Francis Adams was substituted. The convention declared that "congress has no more power to make a slave than to make a king;" and that "it is the duty of the federal government to relieve itself from all responsibility for the existence or continuance of slavery wherever the government possesses constitutional authority to legislate on that subject, and is thus responsible for its existence." In accepting the nomination of this new party, Mr. Van Buren declared his full assent to its anti-slavery principles. The result was that in the state of New York he received the suffrages of more than half of those who had hitherto been attached to the democratic party; and that Gen. Taylor, the candidate of the whigs, was elected. After that time Mr. Van Buren remained in private life on his estate at Kinderhook, with the exception of a prolonged tour in Europe in 1853–'5. On the outbreak of the civil war he declared himself decidedly and warmly in favor of maintaining the republic in its integrity. He left a work entitled "Inquiry into the Origin and Course of Political Parties in the United States," which was edited by his sons in 1867. **II. John**, an American lawyer, son of the preceding, born in Hudson, Feb. 18, 1810, died at sea, Oct. 13, 1866. He graduated at Yale college in 1828, studied law, and was admitted to the bar in 1830; was attached to the legation while his father was minister to England in 1831–'2; was elected in February, 1845, by the legislature of New York, attorney general of the state; and after the conclusion of his term of office on Jan. 1, 1847, was a prominent member of the bar in the city of New York. In the presidential canvass of 1848 Mr. Van Buren greatly distinguished himself as a popular advocate of the free democratic party, and of the exclusion of slavery from the federal territories. He afterward returned to the democratic party. In 1866 he made a tour in Europe, and died on his passage homeward.

VANCOUVER, George, an English navigator, born about 1758, died near London, May 10, 1798. He entered the navy in 1771, and served as midshipman in the second and third voyages of Capt. Cook (1772–'5, and 1776–'80). In 1780 he was created a first lieutenant, and after several years' service in the West Indies returned to England in 1789. Some British subjects settled at Nootka having quarrelled with the Spanish officers, Vancouver with a small squadron was commissioned to go thither, and receive the surrender of Nootka under orders from the court of Madrid to the Spanish commandant. He was also to make a survey of the coast northward from lat. 30°, and to ascertain if there was any communication between the coast and Canada by means of lakes, rivers, or inlets. He sailed from England April 1, 1791, and, after an examination of the Sandwich islands, crossed in March, 1792, to the American coast, and secured the surrender of Nootka. He spent the summers of 1792, '3, and '4 in surveying the coast as far N. as Cook's inlet, wintering in the Sandwich islands. On his return he surveyed a large portion of the W. coast of South America, visiting the chief Spanish settlements, and reached England in October, 1795. He spent the rest of his life in preparing an account of his expedition, which at his death he had nearly finished. It was published (3 vols. 4to, London, 1798) with the atlas of the N. W. coast surveys.

VANCOUVER ISLAND, an island in the Pacific ocean, off the N. W. coast of North America, forming part of British Columbia, between lat. 48° 18′ and 50° 55′ N., and lon. 123° 15′ and 128° 30′ W.; length from N. N. W. to S. S. E. about 275 m., greatest breadth about 85 m.; area variously estimated at from 13,000 to 16,000 sq. m.; pop., exclusive of Indians, about 6,000. It is separated from Washington territory on the south and southeast by the strait of Fuca and canal de Haro, and from the mainland of British Columbia on the northeast by the gulf of Georgia, Johnstone strait, and Queen Charlotte sound, which extends N. N. W. from Johnstone strait to the Pacific ocean, being about 75 m. long and 40 m. in greatest breadth. The coast of Vancouver island is much indented, and is lined with numerous islets. The principal inlets are Nootka sound and Barclay or Nitinat sound on the W. coast, Victoria harbor at the S. E. extremity, Esquimalt harbor 3 m. W., and Nanaimo harbor 65 m. N. of Victoria. The city of Victoria is the chief place, and is the capital of British Columbia. The surface is varied by mountains, hills, and prairies; one valley contains as much as 300,000 acres. Through the middle from N. to S. extends a range of bare and rocky mountains, having a general elevation of 2,000 ft., and culminating toward the south in Mt. Arrowsmith, 5,900 ft. high. The shores are abrupt and rocky, and between these and the central ridge are rounded and fir-covered hills. At the bases of the parallel ridges, in the interior, numerous lakes are formed, which are sometimes connected in a continuous chain, sometimes isolated. The only rivers are the short watercourses which discharge the overflow of the lakes or the surface waters of the ridges; in winter they are torrents, in summer nearly dry. Many springs are charged with sulphuretted hydrogen. The central ridge is composed of metamorphic and trappean rocks, fringed by a belt of carboniferous sandstones and other sedimentary rocks. The chief mineral wealth of the island is coal, anthracite and bituminous. The mines at Nanaimo have been successfully worked for some years, the coal finding a ready sale in San Francisco. There is good limestone on the island. Salt springs exist near Nanaimo and on Salt island, but they are not yet utilized. Some of these springs contain 3,446 grs. of salt to the gallon. The climate is equable and healthful, the summers being cool and the winters mild. Spring and summer are dry, autumn and winter wet. The mean temperature at Esquimalt in 1874 was as follows: winter, 38·5°; spring, 53·5°; summer, 56·8°; autumn, 45·9°; year, 48·7°. The highest temperature observed was 78°, the lowest 13·5°. The rainfall was as follows: winter, 7·28 inches; spring, 1·11; summer, 1·51; autumn, 8·9; year, 18·8. The island is well wooded, and spars and lumber are extensively exported. The chief trees are the pine, fir, spruce, oak, willow, alder, cedar, and maple. The Douglas pine preponderates at the south, and is especially valuable for masts. On the banks of the streams and in the valleys and open tracts there is considerable arable land. Wheat, potatoes, turnips, and other vegetables yield abundantly; oats and barley do not succeed so well. The Indians, of whom there are considerable numbers, live chiefly along the coast, and are peaceable. On the wooded promontories of the S. E. end of the island are old structures of which the use is now unknown. They are circles of stone, 3 to 18 ft. in diameter, and are found in groups varying from 3 or 4 to 50 or more. Those that are in a complete shape are filled in to a height of 3 or 4 ft. with masses of loose stones from the erratic bowlders which are strewn over the whole surface of the country. The supposition that these structures were the dwellings of tribes that have now disappeared from the island derives probability from the circumstance that a tribe on the Frazer river now live in similar habitations.—Possession was taken of the island in 1792 in behalf of Great Britain by the navigator Vancouver, to whom it was surrendered by the Spanish commander Quadra. Vancouver explored its coasts, and gave it the name of Quadra and Vancouver, but the first part is no longer used. In 1843 the Hudson Bay company established a trading post at Victoria. The island was long claimed by the United States, but Great Britain was confirmed in her possession by the treaty of 1846. In 1849 it was granted to the Hudson Bay company for ten years. In 1859 it was erected into a colony, and in 1866 it was consolidated with British Columbia.

VANDALIA, a town and the capital of Fayette co., Illinois, on the W. bank of the Kaskaskia river, at the intersection of the Illinois Central and the St. Louis, Vandalia, Terre Haute, and Indianapolis railroads, 65 m. S. E. of Springfield; pop. in 1870, 1,771; in 1875, about 2,100. It is situated in a good fruit and stock region, and has excellent facilities for manufacturing. It contains a woollen mill, plough and carriage factories, a planing mill and furniture factory, two national banks, two public schools, two weekly newspapers, and five churches. Vandalia was the state capital from 1818 to 1836.

VANDALS, an ancient confederacy of barbarous nations of Germanic race. Schafarik considered them a mixed people of Suevi, Slavs, and Celts, and others have held that they were Wends or Sarmatians; but the best authorities classify them as a purely Germanic race, and generally as Goths. They first appeared on the northern coasts of Germany, whence they migrated S., settling in the Riesengebirge, which from them were called Vandal mountains, and subsequently in Pannonia and Dacia. At the beginning of the 5th century A. D. they turned west, traversed Germany, Gaul, and the Pyrenees, and about 410 settled in N. Spain by the side of the Suevi. Shortly afterward they marched further south, and founded a powerful kingdom in ancient Bætica, which took from them its present name Andalusia (Vandalusia). In 429, under Genseric, they crossed over into Africa with a powerful fleet, and, although numbering not more than 50,000, conquered the whole of the northern coast as far as Tunis, and subsequently gained possession also of Sicily, Sardinia, Corsica, and the Baleares. In 455 they sacked Rome. (See GENSERIC.) Having adopted the Arian creed, they persecuted the orthodox Christians. For more than a century they maintained their power in Africa, with Carthage as capital, until it was overthrown by Belisarius, the general of the emperor Justinian, who conquered their last king Gelimer in 534. After this defeat they disappeared from history, but some suppose that descendants of them are still to be found among some of the Berber tribes with blue eyes and blonde hair. Many of the atrocities and cruelties of which the Vandals have been accused are probably fables.

VANDAMME, Dominique, count, a French soldier, born in Cassel, French Flanders, Nov. 5, 1770, died there, July 15, 1830. In 1788 he enlisted in a regiment at Martinique, returned to France in 1790, and in 1792 became commander of the Mont Cassel or Vandamme chasseurs. He distinguished himself in the army of the north (1793–'4), in that of the Rhine (1795–'7), and in most of the campaigns of the republic, the consulate, and the empire. In 1805 the emperor rewarded his services at Austerlitz with the grand cross of the legion of honor, and in 1808 he was made count. In 1809, under Davoust, he covered himself with glory at Eckmühl. Early in 1812 he was placed in command of Westphalian troops against Russia, but his differences with Jerome Bonaparte, his military superior, led to his withdrawal, and he took no part in that campaign. In March, 1813, he was restored to active service on the Elbe. After the French victory at Dresden (Aug. 27) he was ordered by the emperor to resist Schwarzenberg's advance from Bohemia; but he was surrounded by the allies at Kulm, and after a bloody struggle was obliged to surrender (Aug. 30) with three other generals and 10,000 men. (See KULM.) He was a prisoner in Russia till September, 1814, when he returned to France, but was ordered by Louis XVIII. to remain at Cassel. On Napoleon's return from Elba he was made a peer and commander of a corps, with which he contributed to the victory over Blücher at Ligny; and he defeated the enemy at Wavre during the progress of the battle of Waterloo, after which he covered the retreat of the right wing of the army to Paris, and received the thanks of the chambers. Louis XVIII. banished him, and he lived in the United States till the close of 1819, when he returned home; and in 1820 he was restored to his military rank. On Jan. 1, 1825, he retired from the army.—See *Le général Vandamme et sa correspondance*, by Baron P. E. Albert du Casse (2 vols., Paris, 1870).

VANDERBILT, Cornelius, an American capitalist, born on Staten Island, N. Y., May 27, 1794, died in New York, Jan. 4, 1877. He was averse to education, and at the age of 16 bought a boat with which he plied between the island and New York. At 18 he owned two boats and was captain of a third. At 19 he married, removed to New York, and bought boats, sloops, and schooners; and at 23 he was free from debt and worth $9,000. In 1817 he assisted Thomas Gibbons in building the first steamboat ever run between New York and New Brunswick, N. J., and became captain of her at a salary of $1,000 a year. In 1818 he took command of a much larger and better boat on the same line, his wife at the same time keeping the hotel at New Brunswick and making much money. In 1824 Vanderbilt had full control of the Gibbons line, and brought it up to paying $40,000 a year. In 1827, while still superintending the Philadelphia route, he leased for 14 years the ferry between New York and Elizabethport, N. J., put on new boats, and made it very profitable. In 1829 he left Gibbons, and in the following 19 years till 1848 he built and operated steamboats on the Hudson, on Long Island sound, on the route to Boston, and on the Delaware from Bordentown to Philadelphia. He would put on new and superior boats in opposition to an old line, till he was bought off or drove off his competitors so that he had the monopoly and profits. In 1848–'9 he built the steamship Prometheus, in which in 1850 he sailed for the isthmus of Darien. He had already purchased a controlling interest in the "American Atlantic and Pacific Ship Canal Company," which projected a canal across the isthmus; but for this scheme Vanderbilt substituted a transit route from Greytown at the mouth of the San Juan to San Juan del Sur on the Pacific, which had the advantage over the old transit from Chagres to Panama of saving 700 m. between New York and San Francisco. In 1851 he put three steamers on the Atlantic side and four on the Pacific side, and went into competition with the "United States" and the "Pacific Mail" companies. In 1852, with three more steamers, he started a branch line from New Orleans to Greytown. In 1853 he went to Europe in his steam yacht North Star, and while he was abroad C. K. Garrison and Charles Morgan, holding a large amount of the transit stock, threw him out of the management. On his return he organized an opposition line to Morgan's between New Orleans and Galveston, and in 1854 established an independent line between New York and Aspinwall, with steamers on the Pacific side to compete with the Pacific mail line. He soon compelled a compromise, and once more held the control of the transit company. In 1856 William Walker, then ruling in Nicaragua, seized the property of the transit company, and Vanderbilt, with the assistance of Costa Rica, fomented an insurrection which expelled Walker. The bar at the mouth of the San Juan rendered approach to Greytown difficult, which led to the abandonment of the transit business. In April, 1856, Vanderbilt received a large subsidy for withdrawing his California line, the field not affording profit for two companies. His independent transatlantic line, started in 1855, was abandoned in 1861 by the withdrawal of the Vanderbilt, a steamer costing $800,000, which Vanderbilt gave to the government on the outbreak of the civil war. During his steamship career he owned 21 steamers, 11 of which he built, and with steamboats his entire steam fleet numbered 66; and for many years he had been popularly known as the "Commodore." When he abandoned the water in 1864 his accumulations were estimated at $40,000,000. As early as 1844 he had become largely interested in the New York and New Haven railroad, and in 1845 he began to buy the stock of the Harlem railroad, and in 1864 held the whole of it. In 1859 and subsequently he invested several millions in the mortgage bonds of the Erie road. Soon after coming into possession of the Harlem road he secured a controlling interest in the Hudson River and New York Central railroads, and consolidated the two. From 1873 the Lake Shore and Michigan Southern was operated in conjunction with the New York Central and Hudson River roads as one continuous route 978 m. in extent, and with the Harlem and side lines and branches presenting an aggregate of 2,128 m. subject to one management, representing an aggregate capital of $149,000,000, half of which was said to belong to Vanderbilt and his family. He gave a liberal sum of money for education in the south. (See VANDERBILT UNIVERSITY.)

VANDERBILT UNIVERSITY, an institution of learning in the western suburbs of Nashville, Tenn. It was chartered in 1872 as the Central university of the Methodist Episcopal church, South, but the efforts to raise funds for its organization were unsuccessful. In 1873 Cornelius Vanderbilt of New York gave to the enterprise $500,000, and the institution was named in his honor. He has since increased this amount to nearly $700,000, $300,000 of which is to remain as a permanent invested endowment. One of the conditions upon which this gift was made was that Bishop McTyeire of the Methodist Episcopal church, South, should become president of the board of trust. This post was accepted by Bishop McTyeire, upon whom has fallen the chief responsibility of organizing the institution. L. C. Garland, LL. D., was chosen chancellor, and the Rev. T. O. Summers, D. D., dean of the theological faculty, and *ex officio* vice chancellor. A plot of 75 acres was purchased, the corner stone of the university was laid April 28, 1874, and on Oct. 4, 1875, the institution was opened for students. It has a theological department with four professors, a law department with three, a medical department with eleven, and a department of philosophy, science, and literature with eleven. The total number of students in 1875-'6 was 300. It has a library of 6,000 volumes, scientific apparatus that cost more than $50,000, and extensive geological and mineralogical cabinets. The plan of instruction is elective. The dormitory system is not used; students board in private families. Tuition is free to all in the theological department, and in the literary and scientific department to all preparing for the ministry.

VANDERBURGH, a S. W. county of Indiana, bounded S. by the Ohio river; area, 216 sq. m.; pop. in 1870, 33,145. The surface is generally undulating and the soil very fertile. Bituminous coal is found in abundance. The county is traversed by the Wabash and Erie canal, and by railroads intersecting at Evansville. The chief productions in 1870 were 180,645 bushels of wheat, 553,925 of Indian corn, 56,361 of oats, 13,318 of barley, 54,842 of potatoes, 115,502 lbs. of butter, 167,150 of tobacco, and 9,852 tons of hay. There were 2,856 horses, 1,185 mules and asses, 3,254 milch cows, 2,368 other cattle, 3,157 sheep, and 12,223 swine. The number of manufacturing establishments was 281; capital invested, $3,308,600; value of products, $5,341,517. The chief manufactories were 5 of agricultural implements, 17 of clothing, 2 of cotton goods, 8 of furniture, 10 of iron, 10 of machinery, 19 of tobacco, 3 flour mills, 5 tanneries, 5 currying establishments, 4 planing mills, 8 saw mills, 8 breweries, and 1 woollen mill. Capital, Evansville.

VAN DER GOES. See GOES.

VAN DER HEYDEN, Jan, a Dutch painter, born at Gorkum in 1637, died in Amsterdam, Sept. 28, 1712. He excelled in landscapes, and in painting public buildings and churches, but not in figures, which were added by other artists, chiefly by Adrian Vandervelde. His works include "The London Exchange," the new market and other objects in Amsterdam and Rotterdam, "The Calvary at Cologne," "A Village on the Banks of a River," and "A Street of Rome." The government pensioned him for improvements in fire engines.

VAN DER HOEVEN. See HOEVEN.

VANDERLYN, John, an American painter, born in Kingston, Ulster co., N. Y., in October, 1776, died there, Sept. 23, 1852. Removing to New York at the age of 16, he received instruction in painting from Gilbert Stuart, and in 1796 visited Paris, where he studied five years. He again resided in Europe in 1803–'15, and painted "The Murder of Jane McCrea by the Indians," "Ariadne," a picture very celebrated in its time, and "Marius Sitting among the Ruins of Carthage," which received the gold medal at the Paris exhibition of 1808. After his second return to America, he painted portraits of Madison, Monroe, Clinton, and Calhoun. He was long engaged in superintending the exhibition of panoramic views in a building called the rotunda, erected by himself in the city hall park, New York, which involved him in pecuniary difficulties. Among his remaining pictures are a portrait of Washington for the hall of representatives at Washington, and "The Landing of Columbus," painted for one of the compartments of the rotunda in the national capitol. His last work was a portrait of President Taylor.

VAN DER MEER. I. Jan, the elder, a Dutch painter, born about 1625, died about 1685. He studied in Utrecht and Rome, and became dean of the painters in Amsterdam. He painted the portrait of the prince of Orange, who appointed him comptroller of canal tolls. He excelled in landscapes, sea pieces, and battles, and was distinguished by a brilliancy of coloring not unlike that of Claude Lorraine. **II. Jan,** the younger, son of the preceding, born in Haarlem about 1660, died there about 1704. He was a successful follower of Berghem. His works are seldom to be met with out of Holland. The best is a "View of the Rhine."

VAN DER MEULEN. See Meulen.

VANDERVELDE, or Vandevelde. I. Adrian, a Dutch painter, born in Amsterdam in 1639, died there in 1672. He excelled in figures, and was frequently employed by Ruysdael, Hobbema, Van der Heyden, and other artists, to complete their pictures. **II. Willem,** the elder, a Dutch painter, born in Leyden in 1610, died in London in 1693. He was so distinguished by his drawings of sea fights that the states of Holland provided him with a small vessel for the purpose of following the Dutch fleets and illustrating their manœuvres. In 1675 he was invited by Charles II. to England, and was appointed painter of sea fights to the king, with a pension of £100, which was continued by James II. **III. Willem,** the younger, son of the preceding, born in Amsterdam in 1633, died in London, April 6, 1707. He succeeded his father as marine painter to the king of England, where his pictures are chiefly owned. He was unrivalled in storm pieces.

VAN DIEMEN'S LAND. See Tasmania.

VANDYKE, or Van Dyck, Sir Anthony, a Flemish painter, born in Antwerp, March 22, 1599, died in London, Dec. 9, 1641. He was the most illustrious pupil of Rubens, and finally surpassed him in elegant portrait painting. After visiting England, he went in compliance with the advice of Rubens to Venice, and thence to Genoa and Rome. In both cities he received abundant commissions for portraits, and in the latter produced a fine head of Cardinal Bentivoglio, esteemed one of his masterpieces, besides many altarpieces. In 1627 he returned to Antwerp with a high reputation, and soon after executed for the church of the Augustinians there a celebrated picture representing St. Augustine in ecstasy, supported by angels. For the next five years he was busily employed by ecclesiastical establishments and private patrons in the Netherlands; and to this period may be ascribed numerous "Crucifixions" and "Pietas," impressed with that character of profound sorrow for which he has always been distinguished. Preëminent among them is his altarpiece of the crucifixion in the cathedral at Mechlin, which Reynolds pronounced "one of the finest pictures in the world." The close imitation of Rubens which at first characterized his works was now replaced by a peculiar style in which gracefulness of contour, softness of coloring, and an expression of a deeper and more touching emotion are the distinguishing traits. But his greatest reputation was won by his portraits, which probably led to his being in 1632 invited by Charles I. to England. Soon after his arrival he was knighted, and in 1633 a life pension of £200 was granted to him. "He always," says a contemporary writer, "went magnificently dressed, had a numerous and gallant equipage, and kept so good a table in his apartment that few princes were more visited or better served." Excessive application (it is said that he frequently painted a portrait in a day) and a too lavish indulgence in dissipation, together with the anxieties caused by a search for the philosopher's stone, rapidly undermined his health; and with the desire of repairing his shattered fortunes, he proposed to the king to paint the walls of the banqueting room at Whitehall, but died before completing the bargain for the work. The number of works of all classes attributed to him is enormous, in view of his short life, and of the circumstances under which the last ten years of it were passed. The best of his portraits are in England, prominent specimens being his several portraits of Charles I., those of the earls of Strafford and Pembroke, and many others in the collections at Windsor castle, Hampton court, Blenheim, Althorp, and other famous seats. There are also many in the galleries of Paris, Berlin, and Vienna. A series of 100 small portraits in chiaroscuro of the most eminent of his contemporaries, from which etchings have been made, was executed by him in Antwerp, and is very celebrated. His long lost "Madonna with the Child" is said to have been discovered in 1875 in a German cloister by the Flemish painter George van Haanen. He was buried in St. Paul's cathedral, near the tomb of John of Gaunt.—See "Memoir of Sir A. Van Dyck," with a descriptive catalogue of his etchings, by W. H. Carpenter (4to, London, 1844).

VANE, Charles William Stewart. See LONDONDERRY, MARQUIS OF.

VANE, Sir Henry, an English statesman, governor of the colony of Massachusetts, born in 1612, executed on Tower Hill, London, June 14, 1662. He was the son of Sir Henry Vane the elder, who filled some of the highest state offices during the reigns of James I. and Charles I. He was educated at Westminster school, and was entered at Magdalen college, Oxford; but before matriculation he became alienated from the church of England, and refused to take the oath of allegiance. He visited Holland, France, and Geneva, and then resolved to join the Puritans in Massachusetts. He reached Boston in 1635, and in 1636 was elected governor; but he gave offence by taking part in a bitter religious controversy. He avowed friendship for the principles of civil and religious liberty, and objected to the attacks on Mrs. Hutchinson, many of whose opinions he adopted. An opposition under the lead of Winthrop was organized against him, and in the annual election in 1637 he was defeated; but he was immediately chosen a representative to the general court. The majority of that body declared the election of Vane and his associates void, and they were returned a second time on the next day. In order to put down the Hutchinsonian heresy, a law was passed by the general court that no strangers should be received within the jurisdiction of the colony except by permission of a magistrate. This created such public discontent that Governor Winthrop felt obliged to put forward a "Defence," to which Vane replied in a pamphlet. In August, 1637, he returned to England. In 1640 he was elected a member of parliament from Kingston-upon-Hull, and received in conjunction with Sir William Russell the office of treasurer of the navy. In June of this year he was also knighted. After the dissolution of parliament he was reëlected from the same place to the long parliament. He was a zealous opponent of the royalist party, and after war had broken out between the king and parliament he gave up to the latter the fees of his office of treasurer of the navy, amounting to £30,000 a year. In June, 1643, he was sent to Scotland as one of the commissioners to negotiate an alliance, and by his persuasion the "Solemn League and Covenant" was adopted. During the progress of the war Vane was placed on all commissions empowered to treat with the king, and was also one of the parliament's committee which occasionally accompanied the army. When in 1648 the house of commons discussed the terms of settlement offered by the king, he led the minority which favored their rejection. Disapproving of the "purge" of the parliament which Cromwell effected, he retired to private life. In February, 1649, he became a member of the council of state, and in this position had almost the exclusive direction of the navy and the conduct of foreign wars. He was also at the head of a committee which reported a bill for parliamentary reform, and it was at this period that Milton wrote in his praise one of the finest of his sonnets. The forcible dissolution of the long parliament by Cromwell in April, 1653, brought him into open conflict with that leader. He retired to his estate at Raby castle, and employed himself in writing a theological work, "The Retired Man's Meditations, or the Mysterie and Power of Godliness" (4to, 1655). He also published a political work in the form of a letter to one of the protector's council, and on the occasion of the fast declared by Cromwell in March, 1656, wrote a tract entitled "A Healing Question propounded and resolved." This was adjudged seditious, and for it and his opposition to the course of the protector he was arrested, but was speedily released. While in prison he published a political letter to Harrington, and a work entitled "Of the Love of God, and Union with God." Subsequently efforts were made to induce him to support the protector, but he remained an inflexible republican. After the death of Cromwell he was elected to the parliament of 1659, and was there the leader of the republican party. When the long parliament was again assembled Vane was appointed one of the committee of safety, and subsequently president of the council of state. On the restoration of the Stuarts he was arrested and sent to the tower, and was one of the 20 excepted out of the act of general pardon and oblivion. After an insurrection of the fifth monarchy men he was removed from one prison to another, and at last confined in a castle on one of the Scilly isles, where he remained for two years, spending his time in writing, chiefly on theology. In August, 1660, the lords and commons unitedly petitioned that "if he were attainted, yet execution as to his life might be remitted." But in July, 1661, the commons ordered proceedings against him according to law. He was consequently removed to the tower of London, and on June 2, 1662, arraigned before the court of king's bench. He was brought in guilty, but according to the king's promise the sentence was to be remitted. The courageous bearing of the prisoner alarmed Charles, and after the trial he wrote a letter to the chancellor, saying that if Vane had given new occasion to be hanged, he was certainly too dangerous a man to let live, if he could be honestly put out of the way. Vane suffered the following week; but instead of being hanged, he was beheaded. His bearing was dignified and manly; and in order to prevent him from exciting sympathy, trumpeters were employed to drown his dying speech. It was through his influence that the charter for the Rhode Island colony was procured, and Roger Williams declared that his name ought ever to be held in honored remembrance by her people. Vane's only son was knighted by Charles II.—His life has been written by C. W. Upham, in Sparks's "American Biography."

VAN ERPEN, Thomas. See Erpenius.

VAN EYCK. See Eyck.

VAN HELMONT. See Helmont.

VANILLA (Span. diminutive of *vaina*, a sheath, the pods being supposed to resemble in shape a little knife sheath), the botanical name of a genus of orchids, and the popular name of the fruit or pods of the plant. The species, of which there are but a few, are all climbing plants (an unusual habit with orchids), their slender stems emitting aërial roots by means of which they climb upon and ramble among the branches of trees; the fleshy leaves are heart-shaped at base, and their flowers, which are thick, fleshy, dull-colored, and inodorous, are produced upon small lateral branches; the fruit, when fresh, is about the size of the little finger, somewhat three-cornered, fleshy, firm, smooth, and plump; when cut open it exudes an inodorous slimy juice, which contains numerous spiculæ of oxalate of lime, which have an irritating effect upon the skin; the interior is one-celled, with 12 longitudinal ridges upon the walls, upon which the minute seeds are borne. The most important species is *V. planifolia*, a native of the warmer parts of Mexico, and introduced into Central and South America, and also various parts of the East Indies by cultivators; it requires a warm, moist atmosphere, and can only be cultivated in localities presenting these conditions. Vanilla is propagated by tying a shoot about 3 ft. long to the base of a tree; the plant comes into bearing in three years, and will continue to be productive for 30 or 40 years. The natural conditions have been imitated under glass, and pods of superior quality have been produced in Europe. When quite ripe the pods split longitudinally into two unequal valves, and they are therefore gathered before complete maturity; the drying of the pods is a long process, consisting of alternate wrapping in woollen cloths and heating, and exposing to heat uncovered, a manipulation which develops their peculiar odor and gives them a dark brownish color; they are also oiled in the course of curing. Like those of most other orchids, the flowers of vanilla depend upon insects for aid in fertilization; for a long time the plants, while they grew vigorously and flowered freely in the East Indies, produced no fruit, the proper insect not being present, and fertilization in those countries is now performed artificially. The vanilla pods (or beans as they are popularly called), as found in the shops, are like fleshy flexible sticks, 3 to 8 in. long, $\frac{3}{10}$ to $\frac{4}{10}$ in. wide, flattened, and narrower and hooked at the stalk end; the surface is furrowed lengthwise, and is often covered with minute crystals; within are found innumerable, minute, shining black seeds, imbedded in an aromatic viscid pulp. The odor and flavor of vanilla are peculiar, and to most persons highly agreeable; it belongs to the same class of odors with those of melilot, vernal grass, and Tonqua bean, but is distinct from each. The odor is not due to a volatile oil, but to a crystallizable principle, vanilline, which, having very slight acid properties, has been by some chemists termed vanillic acid; about 1 per cent. is contained in the pods, either as crystals or dissolved in the viscid liquid which surrounds the seeds; it is soluble in ether and alcohol, especially when warm, in boiling water, in fatty and volatile oils, and in alkaline solutions. An interesting fact connected with vanilline is that of its artificial production; Tiemann and Haarman of Berlin in 1874 succeeded in converting coniferine, found in the sap of pines, by means of chemical agents, into vanilline.—The principal supplies of vanilla come from Vera Cruz and Tampico. Its use is that of a condiment or flavoring material, and as such it was known to the Mexicans before the visits of the Spaniards, the natives employing it, as is done at the present day, to mix with chocolate. It was long in use in Europe before its origin was known. In flavoring chocolate it is ground up with the seed, but for candies, ice cream, and cookery, it is most generally employed in the form of an extract; this is prepared by cutting the pods into small pieces, thoroughly triturating them with sugar, then digesting with diluted alcohol, and afterward percolating. Much of the extract is adulterated with Tonqua bean and the cheaper kinds are made solely from that; one familiar with the peculiar and delicate odor of vanilla can detect any admixture of this kind by the smell. It has been said that in all the cases where poisoning has taken place from ice cream vanilla has been the flavor employed. It is supposed by Schroff that in these cases the extract has been prepared from parcels of the drug which have been besmeared with cashew-nut oil.—Wild vanilla is a name given to a *liatris* (*L. odoratissima*), also called hound's-tongue and deer's-tongue, a species of this showy genus found in most of the south-

Vanilla planifolia.

ern states, but especially abundant in the swampy pine woods of Georgia and Florida; it has broad spatulate leaves, those at the base 8 to 12 in. long by 2 or 3 in. broad, and a large branching panicle of heads of purple flowers. The fresh leaves have an unpleasant odor, but in drying a large amount of coumarine is developed (see Tonqua Bean), and they then possess a very strong fragrance. The leaves are collected in large quantities in Florida, and are shipped to northern ports and to Europe; they are used to scent smoking tobacco and snuff, by being cut or ground up with them, and are laid among cigars for the same purpose.

VANINI, Lucilio, an Italian philosopher, born at Taurisano about 1585, burned at the stake in Toulouse, Feb. 19, 1619. After studying at Rome and Padua, he entered holy orders, taught at Geneva, Paris, and Lyons, was obliged to flee to England, where he defended Roman Catholicism, and was imprisoned for some time. He next went to Genoa, and thence to Lyons, where in 1615 he published his *Amphitheatrum Æternæ Providentiæ*, a curious argument against various forms of atheism, which however caused him to be suspected of a desire to spread atheistic doctrines. In Paris appeared in 1616 his volume of dialogues *De Admirandis Naturæ, Reginæ Deæque Mortalium, Arcanis*, which after being sanctioned was burned by order of the Sorbonne. He soon after removed to Toulouse, where his erudition and eloquence attracted numerous pupils, including the children of the president of the parliament. He was nevertheless, after a trial of six months, sentenced to death by the parliament as a free-thinker, despite his submission to the church.—See *La vie et les sentiments de L. Vanini*, by David Durand (Rotterdam, 1717), and *Œuvres philosophiques de Vanini*, by Rousselot (Paris, 1841).

VAN LENNEP. See Lennep.

VANLOO. I. Jean Baptiste, a French painter, born in Aix, Provence, Jan. 14, 1684, died there, Dec. 19, 1745. He was descended from a family of Dutch painters, and found a patron in the prince of Carignano at Turin, who enabled him to study in Rome, and in 1719 presented him in Paris to the regent duke of Orleans, who employed him extensively. This made his fortune as a portrait painter, and he also excelled in other departments of art; and he became a teacher in the academy. From 1738 till about 1740 he was in London, where according to Walpole he "bore away the chief business from every other painter." **II. Charles André,** better known as Carle Vanloo, brother of the preceding, born in Nice in 1705, died in Paris in 1765. He enjoyed a great reputation as a painter of history and portraits. In 1761 he was appointed director of the French academy of fine arts, and in 1762 painter to the king. His son César succeeded him as director, and two of his nephews, Louis Michel and Charles Amédée Philippe, became first painters to the kings of Spain and Prussia.

VANNES (anc. *Civitas Venetorum*), a town of France, capital of the department of Morbihan, near the lagoon of Morbihan, on the S. coast of Brittany, 61 m. N. W. of Nantes; pop. in 1872, 14,690. It is the seat of a bishop, and has a massive cathedral, a theatre, a school of navigation, a communal college, two ecclesiastical seminaries, and manufactories of woollens, cottons, linens, lace, and leather. The port only admits small vessels, but the coasting trade is considerable.

VANNI, Francesco, an Italian painter, born in Siena about 1565, died there, Oct. 25, 1609. He brought himself into general notice by a picture of St. Peter rebuking Simon Magus, for which he was knighted by Pope Clement VIII.; and thenceforth he lived at Siena, where his best works are still to be found. His style resembles that of Federigo Baroccio.

VANNUCCI, Pietro. See Perugino.

VAN OORT, Adam. See Oort.

VAN OOST. I. Jacob, the elder, a Flemish painter, born in Bruges about 1600, died there in 1671. He studied in Italy, and became an imitator of Annibale Carracci. He executed for the churches of Bruges an immense number of pictures, prominent among which is his "Descent from the Cross" in the church of the Jesuits. **II. Jacob,** the younger, son of the preceding, born in Bruges in 1637, died there, Dec. 29, 1713. He was educated in Italy, and settled in Lille. He became known as a historical painter, and excelled in portraits.

VAN OOSTERZEE, Jan Jacob, a Dutch theologian, born in Rotterdam in 1807. He was educated at the university of Utrecht, studied theology, and entered the ministry of the Reformed church. He became pastor at Eemnes and at Alkmaar, and in 1844 was called to the charge of the principal church in Rotterdam; this post he occupied for 18 years, and established his reputation as the ablest pulpit orator and divine in the Reformed church in Holland. In 1862 he was appointed professor of systematic and practical theology at Utrecht. He has written in Dutch: "Image of Christ as presented in Scripture;" "Life of Jesus;" "Christology, a Manual for Christians who desire to know in whom they believe;" "John's Gospel, Apologetic Lectures;" "Theology of the New Testament;" and "Christian Dogmatics." For Lange's *Bibelwerk* he wrote commentaries on the Gospel of St. Luke, the pastoral epistles, and the Epistles to Philemon and of St. James. Several of his works have been translated into other languages; his commentaries, "Theology of the New Testament" (1870), and "Christian Dogmatics" (1874) into English. Van Oosterzee is also the founder and editor, with Doedes, of the "Dutch Annals of Scientific Theology."

VAN OS, Pieter Gerard, a Dutch painter, born at the Hague in 1776, died there in 1839. He formed his style after Paul Potter and Dujardin, and became eminent for his landscapes, with cattle. He served in 1813-'14 as a cap tain of volunteers, and excelled in military subjects, and in etchings from his own designs.

VAN RENSSELAER. I. Stephen, known as "the patroon," an American statesman, born in New York, Nov. 1, 1764, died in Albany, Jan. 26, 1839. He was the fifth in lineal descent from Kiliaen Van Rensselaer, the original patroon or proprietor of the "colonie of Rensselaerswyck," who in 1630 and subsequently purchased land, which in 1637 formed a tract of 48 m. by 24, extending from the immediate vicinity of Fort Orange (now Albany) over the greater part of the present counties of Albany, Rensselaer, and Columbia. His mother was Catharine, daughter of Philip Livingston. He entered Princeton college, but owing to the proximity of the British army removed to Harvard college, where he graduated in 1782. In 1783 he married a daughter of Gen. Philip Schuyler. He was a member of the house of assembly of the state in 1789, and of the senate from 1790 to 1795, when he was chosen lieutenant governor, which office he filled for six years. He presided over the constitutional convention of 1801, and in 1810–'11 he was one of the commissioners for exploring the route and considering the feasibility of a western canal. He was made commander of the cavalry of the state with the rank of general in 1801; and in 1812, in command of the New York militia, he assaulted and took Queenstown, Canada, but was ultimately defeated by the refusal of the militia to go out of the state, whereupon he resigned. After the war he devoted his energies, in connection with De Witt Clinton, to the prosecution of the Erie canal, and from 1816 till his death was one of the board of canal commissioners, and for 15 years its president. He was again a member of the legislature in 1816; in 1819 was elected a regent of the state university, and subsequently its chancellor; in 1820 president of the agricultural board of the state; and in 1821 a member of the constitutional convention. Under his direction and at his expense, geological surveys were made by Prof. Amos Eaton of Albany and Rensselaer counties and along the line of the Erie canal in 1821–'3, and the reports published in 1824. He also employed Prof. Eaton to deliver familiar lectures on natural science through the state. In November, 1824, he established at Troy a scientific school, which was incorporated in 1826 as the Rensselaer polytechnic institute. Fully half of its current expenses were borne by him, and he continued to aid it till his death. He was a member of congress in 1822–'9, and his vote secured the election of John Quincy Adams as president. In 1825 Yale college conferred on him the degree of LL. D.—See "A Discourse of the Life, Services, and Character of Stephen Van Rensselaer, with an Historical Sketch of the Colony and Manor of Rensselaerwyck," by Daniel D. Barnard (8vo, Albany, 1839). **II. Solomon,** an American soldier, a relative of the preceding, born in Rensselaer county, N. Y., Aug. 6, 1774, died in Albany, April 23, 1852. He entered the army in 1792, and as captain took part in the battle of Miami, where he was severely wounded. In 1800 he left the service, but was adjutant general of the New York militia for several years subsequently. In 1812 he was lieutenant colonel of volunteers, and in the assault on Queenstown heights was again seriously wounded. In 1819–'22 he was a member of congress. In 1836 he published a "Narrative of the Affair at Queenstown." **III. Cortland,** an American clergyman, son of Stephen, born in Albany, May 25, 1808, died in Burlington, N. J., July 27, 1860. He graduated at Yale college in 1827, and was admitted to the bar in 1830; but he soon afterward entered the theological seminary at Princeton, was ordained in 1835, and commenced preaching in Virginia. In 1837 he became pastor of the first Presbyterian church in Burlington, N. J., and the same year corresponding secretary of the board of education of the general assembly of the Presbyterian church, both of which offices he filled till his death. He founded the "Presbyterian Magazine," and there is a posthumous volume of his "Essays and Discourses, Historical and Practical" (12mo, Philadelphia, 1861).

VAN SCHENDEL, Petrus, a Belgian painter, born in Breda in 1806. He studied at the academy of Antwerp, and settled in Brussels. Among his best works are market scenes and interiors, contrasting the effects of moonlight and fire light or lamp light.

VANSITTART, Nicholas, Lord Bexley, an English statesman, born in London, April 29, 1766, died in Kent, Feb. 8, 1851. His father, who was governor of Bengal, perished at sea on the voyage to India in 1771. Nicholas graduated at Oxford, and was called to the bar in 1791. From 1796 to 1802 he represented Hastings in parliament. From 1804 he held successively the offices of Irish secretary, secretary to the treasury, and chancellor of the exchequer till 1823, when he was raised to the peerage as Baron Bexley. He was chancellor of the duchy of Lancaster till 1828, when he retired on a pension of £3,000. In default of issue his title became extinct at his death.

VAN SWIETEN. See Swieten.

VAN VEEN, or Venius, Otho, a Flemish painter, born in Leyden about 1550, died in Brussels about 1630. He studied painting in Italy, entered the service of Alessandro Farnese, governor of the Netherlands, at Brussels, and for some years conducted an academy at Antwerp, in which Rubens received his first instruction. His chief works are in the churches of Antwerp and Brussels. He published a "History of the War of the Batavians" from Tacitus, illustrated from his own designs.

VANVITELLI, Luigi, an Italian architect, born in Naples in 1700, died there, March 1, 1773. He was the son of Caspar van Witel, a painter of Utrecht who settled in Italy. He early executed fresco and oil paintings, but afterward devoted himself to architecture, and designed several churches in Urbino, a new port for Ancona, and many religious edifices. In 1725 the pope appointed him architect of St. Peter's, for the protection of the cupola, of which he designed several supports of iron; and he built the vast Augustinian convent at Rome. Subsequently he became architect to Charles III., king of Naples, for whom he constructed a palace and aqueduct at Caserta, and other fine works.—See *Vita di Luigi Vanvitelli*, by L. Vanvitelli (Naples, 1823).

VAN WERT, a N. W. county of Ohio, bordering on Indiana, drained by the St. Mary's and tributaries of the Auglaize river; area, 390 sq. m.; pop. in 1870, 15,823. The surface is level and mostly covered with a heavy growth of valuable timber. The soil is a rich loam resting on a substratum of blue marl. The Miami canal passes along the E. border of the county, which is intersected by the Pittsburgh, Fort Wayne, and Chicago railroad. The chief productions in 1870 were 146,719 bushels of wheat, 25,763 of rye, 162,280 of Indian corn, 90,379 of oats, 35,617 of potatoes, 57,781 lbs. of wool, 270,789 of butter, and 14,799 tons of hay. There were 4,364 horses, 4,340 milch cows, 5,202 other cattle, 19,780 sheep, and 12,945 swine; 2 flour mills, 1 iron foundery, 3 tanneries, 18 saw mills, 1 machine shop, and 2 woollen mills. Capital, Van Wert.

VAN ZANDT, a N. E. county of Texas, bounded N. E. by the Sabine river, and drained by affluents of the Sabine, Neches, and Trinity; area, 875 sq. m.; pop. in 1870, 6,494, of whom 682 were colored. The surface is undulating and the soil fertile. About one third is prairie, and the rest timbered. The chief productions in 1870 were 194,879 bushels of Indian corn, 29,935 of sweet potatoes, 4,088 lbs. of wool, and 2,926 bales of cotton. There were 2,422 horses, 15,179 cattle, 2,406 sheep, and 17,300 swine. Capital, Canton.

VAPEREAU, Louis Gustave, a French author, born in Orleans, April 4, 1819. He studied at the normal school, and in 1842 was secretary to Victor Cousin, whom he assisted in his work *Pensées de Pascal.* From 1843 to 1852 he was professor of philosophy in the college at Tours, being half of the time also professor of German. In 1852, when restrictions were imposed upon philosophical instruction in colleges, he settled in Paris as a private teacher and as a writer. In 1854 he was admitted to the bar, and became the chief editor of the *Dictionnaire universel des contemporains*, editions of which appeared in 1858, 1861, 1865, and 1870, the last in 1888 double-column pages (supplement, 1873).

VAPORIZATION, the conversion of the particles of liquids, and in some instances of solids, into a gaseous condition. When the action takes place from the surface, it is called evaporation; when from the interior of the mass, ebullition. Evaporation takes place at all temperatures with most liquids, but there are some which cease to give off vapor at reduced temperatures; thus if two vessels, one containing oil of vitriol and the other a solution of chloride of barium, are placed together under the exhausted receiver of an air pump, no precipitate of barium will be produced in the latter vessel, showing that no sulphuric acid has evaporated. Most solids before passing into vapor become liquid; but several, as iodine and camphor, pass immediately from the solid to the vaporous condition. Ebullition differs remarkably from evaporation, and with a few exceptions always takes place in a given liquid, subjected to the same external pressure, at the same temperature. (See BOILING POINT, and EVAPORATION.) The amount of vaporization which will take place from any liquid will depend upon its molecular composition, its temperature, and the space in which it is confined. The laws of vaporization are conveniently studied by observing the formation of vapor in the upper end of a barometer tube. A glass tube from 36 to 40 in. long and half or three quarters of an inch in diameter, closed at one end and filled with mercury, may be inverted in a reservoir of that liquid, when the column will fall until it is balanced by the pressure of the atmosphere, and a vacuum will exist in the upper part of the tube. If now a drop or two of sulphuric ether is passed into its mouth, it will on arriving at the surface of the mercurial column meet with no resistance to the vaporization of its particles, and it will consequently fill the previous vacuum, and produce by its expansion a pressure on the surface of the mercurial column, which will therefore fall to such an extent that its weight, added to that of the force of expansion of the ether vapor, will balance the pressure of the atmosphere. The introduction of one or two drops more will cause a further fall of the mercurial column, until after several repetitions the depression of the column will cease, but simultaneously there will be a collection of fluid ether at the surface of the mercury and on the sides of the tube, and no drop of ether subsequently introduced will suffer vaporization unless the temperature is increased. If, however, the tube is warmed, the tension of the ether vapor will be increased; and if the process is continued a point will be reached where all the mercury will be expelled from the tube, and the latter will be filled with the vapor of the ether, the tension of which will then be equal to that of the atmosphere. The temperature at which this takes place is the boiling point of the ether. The ether at any stage of the experiment will boil at the temperature it may have attained when the pressure upon its surface is equal to that which it sustains under the circumstances, viz., the difference between the column in a barometer and that in the experimental tube. For instance, if the column in the latter is 22 in. while the barometer marks 30 in., then the ether, at the temperature to which its vapor has been raised, will boil when sustaining an atmospheric pressure equal to a mercurial column 8 in. high. If the experiment is varied by depressing the tube in the reservoir, it will be seen that, although at the beginning nothing but the invisible vapor of ether occupied the upper part of the tube, when the degree of depression is sufficient, liquid ether will make its appearance. Until this point is reached the mercury will continue to descend to a lower level during the depression of the tube; but as soon as the condensation of vapor into liquid ether begins, the mercury will remain at the same level until all the vapor is condensed, and the upper portion of the tube is filled with liquid ether. When the tube is raised, the mercury will continue to stand at the same level as long as there is any liquid ether in the upper part; but as soon as it all vaporizes, the mercury will begin to rise, and continue to do so with the elevation of the tube. When such a quantity of vapor is contained in a space that it cannot be condensed, the temperature remaining the same, without a portion passing into the liquid state, it is said to be saturated for that temperature. A certain volume of saturated vapor, therefore, when it is heated, ceases to be saturated, and when exerting a pressure equal to that of the atmosphere does not represent the boiling point of the liquid; this it does only at the points of saturation and of equal pressure. (The boiling points of alcohol, ether, water, and other fluids are given in Boiling Point, vol. ii., pp. 793 and 796.) The condition of saturation of a vapor is therefore that of its maximum tension at the same temperature, since it cannot be compressed with partial condensation into a liquid. The more a vapor is removed from its saturation point, either by expansion or by increase of temperature, the more nearly does it resemble in physical properties a permanent gas; and it has therefore been concluded that the so-called permanent gases are only vapors which exist at ordinary temperatures far above their points of saturation, and that by simultaneously lowering their temperature and subjecting them to pressure they could be reduced to a point below that of saturation, and therefore that they could be partially liquefied. In many instances experiment has verified the correctness of this conclusion, as in the liquefaction of nitrous oxide, carbonic anhydride, ammonia, and several other gases. (See Heat, vol. viii., p. 578.) The passage of a vapor into a vessel containing a permanent gas, or into the atmosphere, follows the laws of the diffusion of gases (see Gas, vol. vii., p. 633), and it is found that the combined tension of the gas and the vapor is nearly equal to the sum of the separate tensions of the gas and vapor, when contained in the same space at the same temperature. This is indicated in the increased tension of the atmosphere when it contains a more than usual quantity of invisible watery vapor, and in its diminished tension when such invisible vapor begins to condense and form clouds, as evidenced in the fall of the barometer. The vaporization of liquids under circumstances in which their surfaces are not in contact with the air or any gaseous space, as when water globules are enveloped in oil, presents many remarkable phenomena, some of which are described and explained in the article Boiling Point, as also the effect which substances in solution have upon the vaporization of liquids, as well as the relation of the chemical constitution of a liquid to its boiling point, and an outline of the mode of measurement of the tension of vapors. (See also Expansion, and Steam.)—The following table, from Miller's "Chemical Physics," gives some of the results of Regnault's experiments upon the tension of vapors of several liquids at equal temperatures. The tension is measured by the height of a column of mercury which each vapor will support at a given temperature, the degrees being given on both the centigrade and Fahrenheit scales.

—The vaporization of liquids under greatly increased pressure, as when they are heated in confined spaces, also exhibits remarkable phenomena. Alcohol, when heated in a space a little more than twice its volume to 404·6° F., expands to twice its original volume and suddenly becomes converted into vapor. A glass tube one third filled with water becomes opaque when highly heated, and bursts after a few seconds. The opacity of the tube is due to the chemical action of the water. If the space occupied by the water is one fourth of that of the whole tube, the liquid will be converted into vapor at about 772° F. When chloride of ethyle is heated in a very thick sealed glass tube, the upper surface becomes indistinct at about 338°, and is replaced by an ill defined nebulous zone. As the temperature rises the zone increases in breadth, and becomes more transparent, until finally the tube appears as if empty. Ether becomes completely vaporized in a space three times its volume at about 375°. The passage of a liquid into vapor is attended with a remarkable disappearance of heat, which is converted into another form of energy by which the particles are kept asunder. In ordinary language, such heat is said to become latent. (See HEAT.)

VAR, a S. E. department of France, in Provence, bordering on Basses-Alpes, Alpes-Maritimes, Bouches-du-Rhône, and the Mediterranean; area, 2,349 sq. m.; pop. in 1872, 293,757. The Hyères islands lie off the coast, which is indented by numerous bays, including those of Fréjus, Hyères, and Toulon. The surface is generally mountainous and rugged, particularly in the north and northeast, where it is traversed by offshoots of the Alps, and the only extensive tracts of level ground lie along the coast. The principal rivers are the Verdon and Argens, and there are several extensive lagoons along the coast. Coal, iron, and lead are found, but only the first is worked. About one third of the surface is covered with forests. The soil is not naturally fertile. The manufactures and productions consist chiefly of wine, fruit, silk, paper, leather, coarse woollens, perfumes, and olive oil. The coast fisheries are valuable, particularly those of tunny and anchovies. The department is divided into the arrondissements of Draguignan, Toulon, and Brignoles. Capital, Draguignan.—The river Var, from which the department takes its name, flows through the arrondissement of Grasse in the department of Alpes-Maritimes, detached from that of Var in 1861. It rises in the Maritime Alps, was formerly in part the boundary between France and Italy, and falls into the Mediterranean 5 m. S. W. of Nice.

VARANGIANS. See NORTHMEN, vol. xii., 498.

VARGAS, Luis de, a Spanish painter, born in Seville in 1502, died there in 1568. He completed his studies in Rome, and spent many years in Italy, after which he greatly improved the school of Seville. His death was accelerated by the tortures which he endured in his ascetic frenzy. His portrait of the duchess of Alcalá was regarded as equal to the works of Raphael. Only vestiges remain of his large religious fresco and oil paintings, but several of his most celebrated works are still extant, the best known being his painting representing the human genealogy of Christ, in the cathedral of Seville, called *La generacion.*

VARICOSE VEINS, veins in a state of permanent and preternatural dilatation. The cause of the disease is to be looked for in some obstruction to the return of blood through the affected veins. In some cases the obstruction may be in the heart itself; old cases of heart disease, when the right side of the heart becomes involved, are apt to be attended with a varicose condition of the veins of the neck. The pressure of tumors, aneurisms, &c., upon a large venous trunk, causes a varicose condition of its superficial branches; the pressure of the enlarged uterus in pregnancy is a fertile source of varicose veins of the lower extremities; a varicose condition of the hæmorrhoidal veins constitutes piles, of those of the testicle varicocele. A varicose condition of the veins of the lower extremity, arising from certain occupations which demand the long continued maintenance of the upright posture, from repeated pregnancies, and sometimes from weakness of the coats of the veins themselves, is an exceedingly common complaint. In the natural condition, by the frequently recurring contraction and relaxation of the voluntary muscles, the veins of the lower extremities are alternately filled and emptied. Walking about, or any ordinary form of exercise, therefore facilitates the movement of the blood in the veins. But where a single set of muscles only are kept in constant and unvarying action, as in continued standing at a writing desk or a machine, the movement of the blood is obstructed instead of being aided by the muscular contraction, and it accordingly accumulates in the veins near the point of obstruction, especially in the lower extremities, where it has to mount upward against the force of gravity. The veins are thus unnaturally distended, and when their distention becomes so great that the edges of their opposite valves are drawn away from each other, the weight of the superincumbent column of blood is thrown upon that portion of the vein next below, and thus the affection extends, gradually involving successive portions of the venous system. The veins are sometimes unequally dilated, with knots and protuberances distributed along their course. They are lengthened as well as dilated, their course becoming more tortuous. Sometimes the coats of the vein are thicker, sometimes thinner than natural, or both states may be present in the same vein. They are apt to cause more or less œdema of the affected limb, with a feeling of weight and fulness; sometimes they give rise to or are accompanied by ulcerations which are difficult to heal; occasionally, from gradual thinning of their coats or from accident, they burst and give rise to copious hæmorrhage, which may prove fatal.—The annoyance and suffering attending varicose veins may be very much alleviated by the application of a firm roller, or better still, an elastic stocking, to the affected limb, thus affording equable support to the distended veins; an essential condition is also that the patient should avoid a continued standing posture, which has nearly always so much to do with the original production of the disease. Various operative proceedings have been tried with a view of obliterating the diseased veins and thus curing the disease. These are not always successful, nor are they unattended with danger. The best perhaps is that of M. Velpeau, which consists in passing a needle beneath the trunk of the affected vein, and applying a twisted suture around it; if sufficient inflammation ensue to cause the occlusion of the vein, the needle may be withdrawn in a few days; if not, it is permitted to ulcerate its way through.

VARINAS. See BARINAS.

VARIOLOID, a mild form of smallpox, sometimes occurring in persons previously vaccinated or inoculated, and the virus of which will produce smallpox in those not thus protected. (See SMALLPOX, and VACCINATION.)

VARNA, a seaport town of European Turkey, in Bulgaria, near the N. E. spurs of the Balkan mountains, on the W. coast of the Black sea, 160 m. N. N. W. of Constantinople; lat. 43° 12′ N., lon. 27° 56′ E.; pop. about 20,000, of whom one half are Christians. It occupies an elevated position on the N. W. side of a bay in the gulf of Varna, formed by two rocky promontories, and is defended by a stone wall, batteries, and outworks. It is the seat of a Greek bishop, and contains five churches and eight mosques. The bay is sheltered on the north and northeast from the dangerous winds of the Black sea. The entrances of steamers in 1873 were 255, and the clearances 404; aggregate tonnage, 343,402; the inward and outward sailing vessels comprised 803 small craft with an aggregate tonnage of 89,864. The imports, chiefly manufactured and colonial goods, salt, and coal, amounted to $2,250,000, and the exports, mainly wheat, maize, barley, wool, and tallow, to $2,700,000. The town is connected by rail with Rustchuk and Shumla.—Varna occupies the site of ancient Odessus, a Greek city said to have been founded by the Milesians, and which exercised authority over Tomi, Calatis, Mesembria, and Apollonia, situated on the same coast. Under the Romans it was a town of Lower Mœsia. In the 7th century it fell into the hands of the Bulgarians. Its strategic importance has from the earliest times made it a scene of war. Hunyady and King Ladislas of Poland and Hungary were overwhelmed, and the latter perished, in the battle fought here with Sultan Amurath II., Nov. 10, 1444. In 1610 the Dnieper Cossacks took the town and rescued several thousand Christians from Turkish bondage. Varna resisted the Russians in 1783, although the fortifications proved even at that time inefficient. They have been since greatly improved. In 1828 it surrendered to the Russians after a siege of three months. It was restored to Turkey in September, 1829. In August, 1854, while Varna was occupied as a base of operations against the Crimea by English, French, and Turkish troops, a conflagration destroyed almost half of the town.

VARNHAGEN VON ENSE, Karl August Ludwig Philipp, a German author, born in Düsseldorf, Feb. 21, 1785, died in Berlin, Oct. 10, 1858. He studied in Berlin and at various periods in Halle and Tübingen, and was for some time a private tutor. He joined the Austrian army in 1809, and was wounded and captured by the French at Wagram and exchanged at Vienna, after which (1810) he visited Paris, and next resided alternately at Prague, Vienna, and Berlin. In 1813 he joined the Prussian rising against the French. In 1814 he married in Berlin Rahel Levin (1771–1833), a Jewess of remarkable intellect who had become a Christian, and whose extraordinary social influence had a happy effect upon his career. After assisting Hardenberg, the Prussian minister, at the congress of Vienna, and accompanying the allies to Paris, he became Prussian minister at Carlsruhe. In 1819 he declined the mission to Washington, and henceforth chiefly resided in Berlin. He was early associated with Chamisso, Fouqué, and others in periodical and other publications, and began to publish stories and poems in 1815–'16. In 1822 appeared his *Geistliche Sprüche des Angelus Silesius*, with an introduction, which was reproduced in 1849 with selections from Saint-Martin and with annotations by his wife; and in 1823 his *Goethe in den Zeugnissen der Mitlebenden.* He is best known as a writer of biographies; his first series was *Biographische Denkmale* (5 vols., 1824–'30; 3d ed., 1872). After the death of his wife he published *Rahel, ein Buch des Andenkens für ihre Freunde* (3 vols., 1834), and *Galerie von Bildnissen aus Rahels Umgang* (2 vols., 1836); and his correspondence with her has appeared in a complete edition entitled *Briefwechsel zwischen Varnhagen und Rahel* (6 vols., Leipsic, 1875). His niece Ludmilla Assing has published several volumes of his posthumous works, and Alexander von Humboldt's letters to him. (See ASSING.) Among the many interesting posthumous publications of Varnhagen are his *Tagebücher* (14 vols., Leipsic, 1861–'72), *Blätter aus der preussischen Geschichte* (1868–'9), and *Biographische Porträts* (1871). The third enlarged edition of his select works comprises three parts: the first (6 vols., 1875) entitled *Denkwürdigkeiten des eigenen Lebens*, the second (10 vols., 1875) *Biographische Denkmale*, and the third (in process of completion, 1876) *Vermischte Schriften.*

VARNISH, a solution of resinous matter, used for covering the surfaces of bodies to give them a shining appearance, and to protect them against the air and moisture. The principal substances which enter into the composition of varnishes are: as solid constituents, rosin, amber, mastic, sandarach, lac, elemi, dammar, benzoin, copal, asphalt, and caoutchouc; as solvents, oil of turpentine, linseed, poppy, and a few other vegetable oils, wood naphtha, benzine, and some other constituents of petroleum, alcohol, and ether. As coloring materials, gamboge, dragon's blood, aloes, saffron, annatto, and turmeric are used; to which may be added small quantities of cochineal, French yellow, and other colors, to impart increased brilliancy. Varnishes may be divided into four classes: 1, ether varnishes; 2, spirit varnishes; 3, volatile-oil varnishes; and 4, fixed-oil varnishes. Of the first kind the only one much used is that for repairing the glazing of the colored enamels used in jewelry. It is made by gradually adding five parts of pulverized copal to two parts of sulphuric ether, in a flask which is corked and occasionally shaken for 24 hours or longer. Spirit varnishes made with alcohol are conveniently prepared, and, on account of their rapid drying and leaving no disagreeable smell, are in frequent use in the household for covering various articles of art or *vertu* made by amateurs. When large quantities of spirit varnish are made, a still, with a capital and worm, is usually employed. A stirring rod passes through a stuffing box in the capital. The still is heated by a steam or water bath. The materials being placed in the still, the heat is raised until the alcohol begins to distil. The heat is then lowered, and the solution continued with stirring in an equable manner with as little evaporation as possible. When the stirring rod by its easy turning gives evidence of complete solution, the varnish is passed through a silk sieve and then through porous paper, or allowed to clarify in stone jars. The alcohol which may have distilled over should be added to the varnish. Spirit varnishes are liable to scale off or crack, and are incapable of resisting friction or blows. To diminish this tendency, small quantities of oil of turpentine are often added to them, or some of the softer and more adhesive resins are employed in their composition. The alcohol should not be of less strength than 40° to 36° Baumé (sp. gr. 0·830 to 0·849), as otherwise the resins dissolve with much more difficulty, and the varnish will neither be so brilliant nor so drying. Three ways of making the solution are employed, viz.: 1, by simply digesting the resins, &c., in the proper quantity of alcohol, either in the shade or exposed to the sun, occasionally shaking the bottle; this takes a long time, and many substances cannot be dissolved in this way, but the product has the least possible amount of color; 2, by heating over a water bath, which is much more rapid, but produces more highly colored varnishes; 3, by heating over an open fire, which still more changes the color of the resins, and consequently of the varnish, but it is so much more rapid that it is employed almost exclusively for manufacturing purposes.—Oil of turpentine is almost the only volatile oil employed in varnishes, and the most important one into which it enters is copal varnish. (See COPAL.) The ingredients and modes of preparation are nearly the same as for spirit varnishes. An important difference between the two kinds is, that spirit varnishes are injured in quality by keeping, while those with oil of turpentine are very much improved by it, from the more intimate union which takes place between the resins and the oil.—Fixed-oil varnishes are almost entirely made with linseed oil, for which poppy oil is sometimes substituted, and they generally contain also a large proportion of oil of turpentine. The resins used are almost exclusively the different kinds of copal, and amber. In consequence of the slow evaporation of the solvent, and the large amount of residue from it, they are, of all varnishes, the slowest in drying, but the most durable. (See LINSEED OIL.) For articles of sheet iron, tin, copper, or brass, and for all articles exposed to constant wear and frequent rubbing, they are particularly adapted. (See JAPANNING.) In consequence of the difficult fusibility of the copal, a very different process from that used for spirit and turpentine varnishes must be employed in their preparation. The resin is first melted over an open fire; and when perfectly liquid, the linseed oil, heated to 300° or 400° F., is incorporated with it, and finally the oil of turpentine. It is indeed possible to melt copal directly in boiling oil, and the subsequent addition of a proper quantity of oil of turpentine will bring it to a proper consistence; but as in this case the oil is always more or less burnt, the varnish is both more highly colored and less drying, and this method has been generally abandoned. Great care should be taken that the resins used are of equal fusibility, for if the heat is much raised or long continued after complete fusion of a part, there will be much more color than even if the more infusible parts alone were used. —Besides the four classes of varnishes above described, others are employed for special purposes which can scarcely be included under any of them. Dr. Bolley describes a caoutchouc varnish, which appears to possess valuable properties. The caoutchouc is cut into small pieces and digested in sulphuret of carbon, which forms a jelly with it; and by treating this with benzole, a large proportion will be dissolved. The liquid must be strained through a woollen cloth, and the sulphuret of carbon removed by evaporation in a water bath, after which the liquid may be diluted with an additional quantity of benzole. A gutta percha varnish is made by dissolving one part of gutta percha in 4 or 6 parts of oil of turpentine, and adding 8 or 10 parts of linseed-oil varnish, boiling hot. It is well adapted for varnishing maps and prints, as it does not affect the whiteness of the paper, does not reflect light disagreeably as resinous varnishes do, and is not liable to scale off. Another valuable varnish, called "milk of wax," is prepared by melting a certain quantity of white wax, adding to it while in fusion an equal quantity of alcohol, of specific gravity 0·83, stirring the mixture, and pouring it out upon a porphyry slab, on which it is ground with a muller until it becomes smooth and homogeneous, when water is mixed in by degrees to the amount of four times the weight of the wax, and the emulsion finally strained through canvas. This may be spread with a smooth brush on the surface of a painting, allowed to dry, then fused by passing a hot iron over it, and when cold rubbed with a linen cloth to bring out the lustre. To some such process as this the ancient paintings on the walls of Herculaneum and Pompeii owe their freshness at the present day. Prof. Böttger proposes the following black varnish for zinc: Dissolve 2 parts of nitrate of copper and 3 parts of chloride of copper in 64 parts of water, and add 8 parts of nitric acid. Puscher's method is as follows: He dissolves equal parts of chlorate of potash and sulphate of copper in 36 times as much warm water, and leaves the solution to cool. The zinc castings are immersed for a few seconds in the solution, or the sheets may be washed with a sponge, which turns them quite black with oxide of copper. They are then washed and dried, and the coating is rubbed with a cloth, which imparts a glittering indigo appearance. Milk of wax varnish may then be applied, which gives the surface a deep black color and gloss.—The following comprise some of the best recipes for varnishes:

No. 1 is copal varnish for fine paintings; 2, cabinet varnish; 3, best body copal varnish, for bodies of coaches, &c., which require polishing; 4, carriage varnish for parts not requiring to be polished; 5, best white hard spirit varnish; 6, white spirit varnish for violins; 7, brown hard spirit varnish; 8, turpentine varnish; 9, crystal varnish; 10, amber varnish; 11, paper varnish; 12, sealing wax varnish; 13 and 14, black varnishes.—Besides all these compound varnishes, the liquid resins which exude from many species of trees, especially in China, Japan, Burmah, and India, are used as varnishes, either crude or with slight preparation. (See JAPANNING.) The Chinese varnish is said to be produced by the *augia Sinensis*, and is black when simply dried, but is colored by various pigments. The Japan varnish of Kämpfer and Thunberg is *rhus vernix*, and that of the Malayan islands *stagmaria verniciflua*. The juice of *holigarna longifolia* is used in Malabar for varnishing shields; the Burmese varnish tree is *melanorrhœa*, and a fine liquid varnish is yielded by *vateria Indica* and *V. lanceæfolia*. A resinous juice is also employed by the Feejeeans as a varnish or glaze for their pottery.

VAROLI, Costanzo, an Italian anatomist, born in Bologna about 1543, died in Rome in 1575. He studied medicine at Bologna, and acquired considerable distinction as a teacher of anatomy there, but removed to Rome on being appointed physician to Pope Gregory XIII. He was especially distinguished for his dissections of the brain, which he was the first to examine from the base upward, instead of from above downward, as had previously been the custom. He first fully described the arched bundle of nervous matter passing from side to side across the central parts of the base of the brain, and now known, from its resemblance in form to a bridge, as the *pons Varolii.* His principal works are *De Nervis Opticis, nonnullisque aliis, præter communem opinionem in Humano Capite observatis* (Padua, 1573), and *De Resolutione Corporis Humani*, published after his death (Frankfort, 1591).

VARRO, Marcus Terentius, a Roman scholar, born in the Sabine town of Reate in 116 B. C., died in 28. He received a liberal education, held a high office in the navy in the wars against the pirates and against Mithridates, and at the commencement of the civil war was serving in Spain as legate of Pompey. When Cæsar marched into that country after the reduction of Italy, Varro was obliged to surrender his forces; but still adhering to the aristocratic party, he joined Pompey in Greece and remained faithful to him until the victory of Pharsalia (48) had made Cæsar master of the Roman world. Varro's villa at Casinum was taken and plundered by Antony, but Cæsar treated him kindly, and employed him to superintend the collection and arrangement of the works in the library at Rome designed for the public use. From this time Varro lived in retirement. During the second triumvirate he was put by Antony on the list of the proscribed, but by the aid of friends his life was saved, though his libraries were destroyed. Augustus appointed him superintendent of the library founded by Asinius Pollio. According to a list traceable to himself, Varro wrote 74 works in 500 or 600 books, including several in metrical form, and prose treatises on nearly all branches of knowledge and literature. All these have perished except the *Rerum Rusticarum Libri III.*, the only one that has been preserved entire, and *De Lingua Latina*, of the original 24 books of which only books v. to x. remain in a mutilated state. The former is a dialogue after the manner of Cicero's philosophical writings, but far more graphic, and replete with puns on the names of his characters. The best edition is in the *Scriptores Rei Rusticæ Veteres Latini* of J. G. Schneider (4 vols. 8vo, Leipsic, 1794–'7). It has been translated into English by the Rev. T. Owen (Oxford, 1800). The linguistic value of Varro's grammatical fragment is very unequal, and the style is uncouth and awkward. The first edition is by Pomponius Lætus (Rome, 1471); recent editions are by Müller (Leipsic, 1833) and Egger (Paris, 1837). Varro was sometimes called Reatinus from his estate at Reate.

VARRO, Publius Terentius, a Latin author, surnamed Atacinus, from the Atax (now Aude), a river of Gallia Narbonensis, where he was born, according to Jerome, in 82 B. C., died in 37. At first he wrote satires and epic and elegiac poems, but he became more famous as a translator of Greek poems, as the *Argonautæ*, *Chorographia*, and *Ephemeris*. Only fragments of his works are extant.

VARUS, Publius Quintilius. See ARMINIUS.

VAS (Ger. *Eisenburg*), a county of Hungary, in the Trans-Danubian circle, bordering on Lower Austria, Styria, and the counties of Oedenburg, Veszprém, and Zala; area, 1,944 sq. m.; pop. in 1870, 331,602, chiefly Magyars and Germans, and about three fourths Catholics. It is traversed in the west and south by spurs of the Alps. The principal river is the Raab. The chief products are grain, wine, and fruit. Vas is called after the village of Vasvár, once a free town and a strong fortress under Matthias Corvinus. The capital is Szombathely (anc. *Sabaria;* Ger. *Steinamanger*); another important town is Güns.

VASA. I. A W. län or government of Finland, Russia, bordering on the gulf of Bothnia; area, 16,146 sq. m.; pop. in 1872, 310,937. The surface is level, and there are fewer lakes than in any other part of Finland. **II.** A town, capital of the län, on a small bay of the Baltic, 230 m. N. W. of Helsingfors; pop. in 1867, 4,551. Its port has become greatly obstructed by sand.

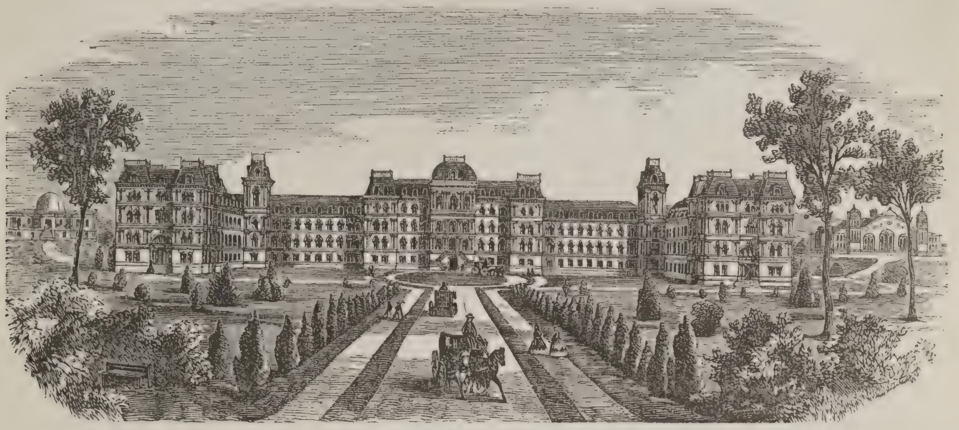
VASA, Gustavus. See GUSTAVUS I.

VÁSÁRHELY, also called Hód-Mezö-Vásárhely, a town of S. Hungary, in the county of Csongrád, near the E. bank of the Theiss, 14 m. N. E. of Szegedin, with which it is connected by rail; pop. in 1870, 49,153, mostly Protestants. It has a Protestant gymnasium and well attended fairs. The inhabitants are nearly all agriculturists of Magyar or Slavic race. (For Vásárhely in Transylvania see MAROS-VÁSÁRHELY.)

VASARI, Giorgio, an Italian artist, born in Arezzo in 1512, died in Florence, June 27, 1574. He belonged to a family of painters, was brought up at Florence by his kinsman Cardinal Passerini, together with Ippolito and Alessandro de' Medici, and became the friend and pupil of Michel Angelo and Andrea del Sarto. After returning to Arezzo in 1527 he produced his first religious painting. Subsequently he was also engaged as a sculptor in that city and in Rome, where he acquired a fortune. His chief works are a "Descent from the Cross" in Rome; the design for the villa Giulia, finally executed by Michel Angelo and Vignola; decorations for the Medici palace at Florence, including the "Adoration of the Magi;" and "Martyrdom of St. John the Baptist" at Rome, one of his masterpieces. He was one of the founders of the Florentine academy of fine arts. His biographical work on Italian artists is still a standard authority. It is entitled *Le vite de' più eccellenti pittori, scultori e architetti* (in 3 parts, Florence, 1550; 2d ed. enlarged, 2 vols. 4to, 1568; best recent ed., 13 vols. 12mo, Florence, 1846–'57). It has been translated into English by Mrs. Jonathan Forster (5 vols., London, 1850–'52).

VASCO DA GAMA. See GAMA.

VASSAR COLLEGE, an institution of learning near Poughkeepsie, N. Y., founded by Matthew Vassar for the advanced education of young women. The founder was born in Norfolk county, England, April 29, 1792, and in 1796 came to the United States with his father, who settled on a farm near Poughkeepsie. The father engaged in brewing, in which his son subsequently accumulated a large fortune. In February, 1861, Mr. Vassar delivered to trustees, incorporated for the purpose by the legislature in the preceding January, $408,000 for the founding of Vassar female college, accompanying the gift with a statement of his wishes concerning the plan of the college and its system of instruction. About half of this sum was to be expended in the erection of buildings, for which he gave a beautiful site of 200 acres nearly two miles E. of Poughkeepsie and a little greater distance from the Hudson river, and the remainder to form an endowment for the partial support of the professorships, &c. It was not his purpose to make it a charity school, but to afford to women opportunities for obtaining a collegiate education at moderate cost, and gratuitous instruction to those unable to pay for it. All sectarian influences were to "be carefully excluded, but the training of our students should never be intrusted to the skeptical, the irreligious, or the immoral." Mr. Vassar died June 23, 1868, and left a bequest of $50,000 to constitute a lecture fund, the income to be used in maintaining, without extra charge to the students, lectures on literature, science, and art; $50,000 as a library, art, and cabinet fund; and $50,000 as an "auxiliary fund for aiding students of superior promise and high scholarship, who are unable to pay the full charges for board and tuition in the college." The construction of the main college building was completed in 1865. It is of brick with blue freestone trimmings, 500 ft. in length, with a breadth at the centre of 200 ft., and at the transverse wings of 164 ft. The central building and the wings are five stories high, and the connecting parts four stories. Within the edifice are five independent dwellings for resident officers, accommodations for about 400 students, recitation and lecture rooms, a chapel, and apartments for a library and reading room, philosophical apparatus, laboratories, &c. Apart from the main edifice are an observatory and a spacious museum, containing an art gallery, a studio, cabinets of natural history, a lecture room, music rooms, a hall for literary societies, a hall for calisthenics, and a bowling alley. In 1861 Prof. Milo P. Jewett was chosen president of the institution, and he subsequently visited Europe to obtain information for the promotion of its organization. In 1864 he resigned, and was succeeded by John H. Raymond, LL. D., who still holds the office (1876). In September, 1865, the college was opened with 8 professors and 20 other instructors, besides the president and lady principal, and 300 students, which number was increased during the year to 350. In 1867 the name of the institution was changed from Vassar female college to its present form. There is a preparatory course of study of about two years, and a collegiate course of four years. Special collegiate courses are also provided for advanced students not under 20 years of age. Applicants for admission to the preparatory classes must be at least 15 years of age, and to any college class at least 16. In all cases admission must be preceded by examination. To the middle of the sophomore year all studies are prescribed, except that the student has the option of taking Greek, German, or French. For the remainder of the course the student must pursue at least three studies, which may be selected by herself subject to the approval of the faculty. Students are encouraged to take, in addition to the regular course, one study in drawing, painting, and modelling, or in music. Students who complete the regular course receive the first or baccalaureate degree. A candidate for the second degree must pass examination in studies which have been approved by the faculty as equivalent to a post-graduate course of two years, and must present a satisfactory dissertation on some literary or scientific subject. The price of board and tuition for each student is $400 for the college year of 40 weeks. An extra charge is made for private lessons in music and the arts of design. Provision is made by the auxiliary fund for remitting to indigent students one half the charge for board and tuition. In 1875–'6 there were, besides the president and lady principal, 9 professors, of whom 3 were women, 22 female teachers, and 370 students, of whom 202 were pursuing collegiate and 168 preparatory studies. Of the students, 114 were from New York, 253 from other states, 2 from Canada, and 1 from Russia. The total number of graduates of the college to the close of 1875–'6 was 323. The college has a library of 9,000 volumes, and valuable philosophical apparatus.



Vassar College.

VATER, Johann Severin, a German linguist, born in Altenburg, May 27, 1771, died in Halle, March 16, 1826. He was a student and professor at Jena and Halle, in 1809 was transferred to Königsberg, and in 1820 resumed his chair at Halle. Although he taught theology, he is chiefly known as a philologist. His works include a Hebrew grammar (1797); *Handbuch der hebräischen, syrischen, chaldäischen und arabischen Grammatik* (1801); a Polish (1807) and a Russian grammar (1809); a continuation of Adelung's *Mithridates* (1809–'17); and *Literatur der Grammatiken, Lexika und Wörtersammlungen aller Sprachen der Erde* (1815). He also edited and continued Henke's *Allgemeine Geschichte der christlichen Kirche* (1818–'23).

VATICAN, the papal palace at Rome, so called from its situation on the Mons Vaticanus, at the extreme N. W. part of the city. It adjoins the basilica of St. Peter, and is a little less than half a mile from the castle of Sant' Angelo, with which it communicates by a covered gallery built by Pope John XXIII. early in the 15th century. The palace, one of the most magnificent in the world, has grown up by degrees, and consequently exhibits a great want of architectural harmony. There was a palace attached to St. Peter's certainly in the time of Charlemagne, and probably before the reign of Constantine. It was rebuilt by Innocent III. (1198–1216), and enlarged by Nicholas III. (1277–'81), but did not become the permanent residence of the popes until after their return from Avignon in 1377. Very little of the present edifice is older than the time of Nicholas V. (1447). The renovation of the old palace, which he commenced, was completed by Alexander VI. (1492–1503), after whom that part of the building is now called the *appartamento Borgia.* The Sistine chapel was added by Sixtus IV. in 1474, and the Pauline chapel by Paul III. in 1534. Innocent VIII. (1484–'92) constructed the Belvedere villa a short distance from the palace, and Julius II. (1503–'13) connected it with the Vatican by means of the celebrated *loggie* and a terraced court. To Julius II. is also due the foundation of the museum. Pius VII. constructed the *braccio nuovo* for sculptures; Gregory XVI. added the Etruscan museum; and Pius IX. has added a fourth side to the cortile di San Damaso. The portion of the Vatican which is now the ordinary residence of the popes lies on the E. of the *loggie*, and was built chiefly by Sixtus V. (1585–'90) and Clement VIII. (1592–1605).—The whole palace, which is rather a collection of separate buildings than one regular edifice, occupies a space of 1,151 by 767 ft., and has 200 staircases, 20 courts, and 4,422 rooms. The *scala regia*, or great staircase, is a masterpiece of Bernini, and chiefly remarkable for its perspective. It leads to the *sala regia*, built by Antonio di Sangallo as an audience hall for the reception of ambassadors, and decorated with frescoes by Vasari, Marco da Siena, Taddeo and Federigo Zucchero, Giuseppe Porta, and others. The Sistine and Pauline chapels open into this hall. The former contains, besides the magnificent frescoes of the ceiling, Michel Angelo's first masterpiece in painting, his "Last Judgment," together with frescoes by Perugino, Ghirlandaio, and others, representing passages in the lives of Christ and Moses; the latter possesses Michel Angelo's frescoes of the "Conversion of St. Paul" and "Crucifixion of St. Peter." The chapel of San Lorenzo has a series of remarkable frescoes by Fra Angelico. The *stanze* of Raphael is the name given to four chambers decorated by the hand of that great master; the paintings in one represent events in the lives of Leo III. and Leo IV.; in another are illustrations of the sciences of theology, philosophy, poetry, and jurisprudence; in the third, the triumphs and miracles of the church; and in the fourth, the sovereignty of the church. The frescoes on the roof of the first are by Perugino, and the last contains only two figures by Raphael, the rest having been completed after his death by Giulio Romano and others. The *loggie*, already referred to, form a triple colonnade around three sides of the court of San Damaso, the uppermost story supported by columns, and the two lower by pilasters. They were built after designs by Bramante, and on one side of the court were painted from the designs of Raphael; they have been much injured by exposure to the weather and other causes, but are now protected by glazed sashes. The museum is one of the most magnificent collections of the kind ever made. Among its principal features are the gallery of inscriptions, containing over 3,000 specimens of ancient sepulchral inscriptions and monuments; the *museo Chiaramonte*, devoted to ancient sculptures, with the *braccio nuovo*, a fine hall added to it in 1817, and containing a semicolossal statue of an athlete, supposed to be the famous *Αποξυόμενος* of Lysippus; the *museo Pio-Clementino*, devoted to works of the same class accumulated by Julius II., Leo X., Clement VII., Paul III., and especially Clement XIV. and Pius VI., and possessing the Torso Belvedere and the sarcophagus of Scipio; the *cortile di Belvedere*, containing bass-reliefs, statues, sarcophagi, baths, &c., among which are the Laocoön and the Apollo Belvedere; the halls of the animals, of the busts, and of the Muses, so named from the character of their principal statues; the gallery of statues, in which are the Apollo Sauroctonos and the supposed Cupid of Praxiteles; the cabinet of the masks; the hall of the Greek cross, with the sarcophagi of Sts. Helena and Constantia, the mother and daughter of Constantine; the gallery of the candelabras, the *sala degli Arazzi*, so called from the "tapestries of Raphael" manufactured at Arras in 1515–'16; and the hall of the *biga*, so called from an antique two-wheeled chariot in white marble. The Etruscan museum contains 12 chambers, filled with relics of the ancient inhabitants of Italy. The Egyptian museum, commenced by Pius VII., is inferior to many similar collections in other parts of Europe. The picture gallery contains greater treasures than any other in the world, though the whole catalogue barely numbers 50 paintings. Among these are Raphael's "Transfiguration," "Madonna di Foligno," and "Coronation of the Virgin;" Domenichino's "Communion of St. Jerome;" and works by Titian, Andrea Sacchi, N. Poussin, Guido, Caravaggio, Baroccio, Perugino, Guercino, Fra Angelico da Fiesole, Pinturicchio, Correggio, Melozzo da Forli, Andrea Mantegna, and Paul Veronese.—The library was founded in 1378, and now contains 105,000 volumes and 25,500 manuscripts, in a building erected by Sixtus V. in 1588. The manuscript collection, though not the largest, is the most valuable in the world.

VATICAN, Council of the, the 20th œcumenical council according to the Roman Catholic church, convened Dec. 8, 1869. The design of calling a general council was first intimated in a consistorial address of Pius IX., delivered June 26, 1867, to the prelates assembled in Rome to celebrate the 18th centenary of the martyrdom of St. Peter and St. Paul. The prelates, in a joint answer presented to the pope on July 1, expressed the wish that he would soon execute his design. On June 6 a circular had been prepared by Cardinal Caterini, prefect of "the congregation of the council (of Trent)," containing a schedule of 17 important points of church discipline and morality on which, as well as on others suggested to the bishops from personal observation, an examination was requested with an answer within four months. The points submitted regarded principally the sacredness of Christian matrimony; the tone required in preaching, and the care to base all pulpit instruction on revealed truth; the importance of securing Christian influences in schools; the necessity of a more elevated preparatory training in ecclesiastical seminaries, and the means of encouraging higher culture in sacred and profane knowledge among the priesthood; the policy of encouraging the multiplication of religious associations bound only by simple vows; how to provide worthy incumbents for vacant episcopal and parochial offices, and how to regulate the exercise of episcopal authority over the inferior clergy. Most bishops communicated this document to their priests; and thus the whole Catholic world was already preparing for the approaching council when the bull of indiction, *Æterni Patris*, was issued, June 29, 1868, appointing the council to open in the Vatican basilica, Dec. 8, 1869. For the first time in the history of general councils, no invitation was extended to any of the European governments; only the bull of convocation expressed the hope that the various governments would leave the bishops free to attend. The Russian bishops alone were not allowed this freedom. On Sept. 8, 1868, the pope addressed a letter of invitation to the bishops of all the oriental churches not in communion with Rome; and on Sept. 13 he issued the letters apostolic, *Jam vos omnes noveritis*, to "all Protestants and non-Catholics," exhorting them "to consider whether they were walking in the way commanded by Christ and leading to eternal salvation." The Greek Orthodox church returned no answer, though a few of its bishops manifested a desire to accept the pope's invitation. The Armenian patriarch, Boghos, accepted, and induced several of his associates to do so; but he was forced to resign his office in consequence. In the Protestant world, the grounds on which the pope based his appeal were denounced as an unwarranted assumption of right. In Germany Reinhold Baumstark of Constance and Wolfgang Menzel of Stuttgart, editor of the *Literaturblatt*, were among the few who spoke favorably of the invitation to Protestants. In England Dr. Cumming, in the name of the church of Scotland, inquired whether Protestants would be permitted to present to the council arguments in support of their position toward the church of Rome, and the pope replied, on Sept. 4 and Oct. 30, that while no discussion could be permitted of doctrinal questions already defined, he was sincerely desirous of meeting all who believe that their separation is based on solid reasons, by referring them for consultation to the most eminent and prudent theologians selected by himself. No special appeal having been made to the Jewish people, two converts of that race, the brothers Joseph and Auguste Lémann of Lyons, published *La question du Messie et le concile du Vatican*, which the pope praised in a brief; a further petition, presented by the authors to the council itself, requesting that the Jews should be specially invited, produced no response.—A congregation of cardinals, assisted by theologians representing the principal Catholic countries, was appointed immediately after the publication of the bull of indiction, to take in hand the general work of preparation. To this were adjoined six commissions, on ceremonies, on ecclesiastical policy, on oriental churches and missions, on religious orders, on dogmatic theology, and on church discipline, respectively, each presided over by one of the seven cardinals. Up to the opening of the council no place was given to the doctrine of pontifical infallibility on the *schemata* or programmes submitted to the congregations and commissions; but from the first indiction of the council, the religious as well as the political press began to discuss the opportuneness as well as the danger of making this doctrine an article of faith. In France, Belgium, Holland, and Germany (where many of the bishops and inferior clergy had been taught the Gallican views of papal prerogatives, and where the majority of statesmen and lawyers upheld extreme Gallican principles concerning the superiority of a general council to the pope, the absolute independence of the state of all spiritual authority, and the right of national churches to regulate their own temporal affairs) all the controversies of the middle of the 17th century were revived. The Jansenists, who were numerous in Holland, and influential though few in France and Germany, were foremost in their attacks on the ultramontanes. Napoleon III. was personally in favor of holding the council, and not opposed to a definition of the received doctrine on infallibility; but the leading members of the French government were known to be hostile to both projects. The Austrian government thought the revival of this controversy untimely and perilous; while at Munich the prime minister, Prince Hohenlohe, and his associates followed the impulse given them by Döllinger; and a circular, now known to be the work of the latter, was addressed by Bavaria, April 9, 1869, to the Roman Catholic courts, calling their attention to the projects entertained by the promoters of the council. "The only dogmatic thesis," the circular affirmed, "which Rome wishes to have decided by the council, and which the Jesuits are now agitating throughout Italy and Germany, is the question of pontifical infallibility. This pretension, once become a dogma, will evidently have a wider scope than the purely spiritual sphere, and will become eminently a political question; for it will raise the power of the sovereign pontiff, even in temporal matters, above all the princes and peoples of Christendom." In June a second circular from Prince Hohenlohe invited the governments to unite in preventing the meeting of the council. This was seconded by the Italian prime minister, Menabrea; and a joint note from Italy and Bavaria urged Napoleon III. to withdraw his troops from Rome during the sitting of the council. The Bavarian ministry addressed a series of questions to the theological faculty of the university, regarding the embarrassments likely to ensue between church and state if the teaching of the syllabus were made a doctrine of faith. These questions were discussed throughout Germany. The answer of the faculty, though guarded on the main doctrinal points, was unfavorable to the infallibilist view, and arraigned the Jesuits for revolutionizing the public and private teaching of the church. The publication of this answer increased the opposition to the council, and Bavaria sent to the courts of southern Germany a circular urging them to address a similar series of questions to their respective universities. Simultaneously with this an address embodying the most formidable objections to the ultramontane doctrines in general, and in particular against the syllabus, as well as the opportuneness of any new dogmatic definitions, was printed in the principal European languages, and sent to all the members of the Roman Catholic hierarchy. This was the work of a committee of laymen, who had their centre of action at Coblentz. Another document, known as the "Coblentz Address," was at the same time published in that city, purporting to be a lay remonstrance to the archbishop of Treves on the proposed action of the council, and submitting a large plan of church reform, the chief points of which were afterward embraced in the changes advocated by the Old Catholics. They demanded that the coming council should decree the separation of the church from the state, the government of parishes by local boards, that of dioceses by diocesan synods, that of national churches by national councils, the nomination of bishops by the people, the suppression of the *Index Expurgatorius*, &c. An identical address signed principally by laymen, which obtained the assent and support of the faculties of the leading German universities, was presented to other bishops. Count Montalembert from his deathbed adhered by letter to the Coblentz address. The Vienna *Neue freie Presse* of June 16 denounced the agitation as a conspiracy having its centre in Munich, and Dr. Döllinger for its promoter. In France the periodical *Correspondant* advocated the views of the German opposition, but was combated by Louis Veuillot in the *Univers*, by Laurentie in the *Union*, by the *Tijd* of Amsterdam, and by the *Catholique* of Brussels. As the time for the meeting of the council approached and the discussions of the public journals increased in vehemence, MM. Baroche, Rouher, Daru, and others, by their speeches in the senate and their published correspondence, reëchoed the fears expressed by the statesmen, journalists, and theologians of Germany. The series of letters on papal prerogatives that appeared in the Augsburg *Allgemeine Zeitung* in March, reappeared in a more elaborate form at Leipsic in the anonymous book *Der Papst und das Concil*, by "Janus," and this was supplemented by *Die Reform der römischen Kirche in Haupt und Gliedern*. The bishops of Germany met at Fulda in September, and signed a joint pastoral letter, in which they pronounced groundless the fears about the supposed dangers to the constitution of the church, to her legitimate relations with the civil power, to the happiness and liberty of peoples, and to the just rights of science and civilization. They repelled the motive attributed to Pius IX. of wishing to make himself an absolute monarch, the infallible arbiter of doctrines as well as of temporal interests, and of laboring to be the head of a controlling and tyrannical party in the church. Bishop Maret, dean of the theological faculty of the Sorbonne, published in September *Du concile général et de la paix religieuse* (2 vols.), which was dedicated to the pope, but advocated the purest Gallicanism, and was heralded by the praise of the liberal press, and by a violent controversy between the bishop and the *Univers*, the leading ultramontane journal. This work was either repudiated or condemned by all but three or four of the French bishops. Between Bishop Dupanloup of Orleans, on the one hand, and Archbishops (afterward Cardinals) Dechamp of Mechlin and Manning of Westminster, a public correspondence took place just as the prelates of all countries were taking their departure for Rome. In November Archbishop Darboy of Paris, who had publicly taught as professor the doctrine of papal infallibility, but was opposed to the opportuneness of a conciliary definition, reproduced the main points of the circular issued from Fulda, in a pastoral letter, which produced a deep impression.—On Nov. 27, 1869, the pope published the official letter, *Multiplices inter*, establishing the order to be followed in the celebration and deliberations of the council. In this he repeats the chief reasons for holding it: the extirpation of error, providing a remedy for the ills of the church, the reform of morals, and the restoration of discipline. Three other points are deserving of notice: the right and manner of proposing any matter to the council, the manner of proceeding in general congregation or committee of the whole, and the ceremonial of the solemn or public sessions to be held in presence of the pope himself. As to the first, every bishop has a right to make a proposition to the council; but this must be in accordance with the common teaching of the church, and be previously submitted to the special committee or congregation charged with examining such propositions. If approved by the committee, it is referred to the pope, who decides on the opportuneness of bringing it before the council. As to the second, it is decreed that the doctrinal or disciplinary *schemata* or resolutions drawn up during the 18 previous months by the preparatory commissions shall be distributed among the members of the council in good time before the general congregations; that four deputations or special committees shall be established by the council, on faith, church discipline, religious orders, and oriental rites, each to consist of 24 members elected by ballot in the council; that in every general congregation, after discussing the matters prepared and submitted, a vote shall be taken thereon, and decrees adopted to be promulgated afterward in public session; in these, after the reading of the decrees thus prepared, the votes of all the members present shall be taken and counted before the pontifical throne, in presence of the pope, who will then sanction them. On Dec. 2 a prosynodal or preparatory assembly of all the prelates present in Rome was held, the pope presiding. On the evening of the 7th Pius IX. with a numerous cortége went to the church of the Apostles to inaugurate nine days of public prayer for the divine light on the approaching deliberations. With the first break of day on the 8th, the artillery of the castle of Sant' Angelo and the bells of all the churches in Rome pealed forth. By 6 o'clock the naves of St. Peter were filled, as well as the piazza and the streets leading to it. At 9 the head of the procession began to appear on the square; and more than an hour elapsed before it could reach the left arm of the transept, which had been partitioned off and furnished as the council hall. Mass was celebrated by Cardinal Patrizzi, vice dean of the sacred college, and Bishop Fessler of St. Pölten in Austria, secretary of the council, then placed the book of the Gospels on a throne prepared for it on the altar; the archbishop of Iconium and vicar of the Vatican basilica, Puecher-Passavalli, a determined inopportunist, preached the opening sermon, and an hour was consumed by the members in paying the prescribed homage to the pope. After appropriate devotional services all who had not a right to be present at the proceedings of the session left the council hall. Two decrees only were promulgated, the one declaring the œcumenical council of the Vatican duly opened, and the other appointing the next public session to be held on Jan. 6, 1870. There were present 49 cardinals, 9 patriarchs, 4 primates, 123 archbishops, 481 bishops, 6 privileged abbots, 22 abbots general, and 29 superiors general of religious orders; in all, 723 members of the council by right or by invitation. Seven general congregations were held between Dec. 8 and Jan. 6, and were employed both in discussing the prepared *schemata* and in electing the members of the four deputations called for in the letters apostolic of Nov. 27. The deliberations on *schemata* began on Dec. 30, and were confined to questions of discipline. It became clear in the first days of January that among the persons connected with the various deputations and commissions, there were a few who did not scruple to violate the oath of secrecy; and in spite of an admonition to the members of the council, the Augsburg "Gazette" continued to publish letters from its Roman correspondent professing to describe the most secret transactions of the committees. Still no place was given in the *schemata* to the question of infallibility at the beginning of March. Two memoirs presented to the members of the council about this time brought the question of opportuneness to a crisis. The first, bearing no date or printer's name, was entitled *Postulata a pluribus Galliarum Episcopis Sanctissimo D. nostro Pio Papæ IX. et Sacrosancto Concilio Vaticano reverenter proposita*, and concluded with the demand "that no new definitions of faith should be made, except such as were absolutely necessary." The names of the French bishops were not mentioned, but the document was freely circulated among them. The second memoir was a *postulatum* signed by 40 prelates of various countries, asking for a formal and explicit definition of the pope's infallibility while exercising his teaching office toward the entire church; and on March 6 it was officially announced that the commission on *postulata* had recommended and the pope had approved action on this petition, and that a special chapter on this subject should be introduced into the *schema* of the forthcoming constitution "On the Church of Christ." The first discussion on infallibility was fixed for March 18, and the prelates who intended to speak on it in general congregation sent in their names. Meanwhile the French minister of foreign affairs, Count Daru, yielding to the pressure of other governments, wrote to Count de Banneville, the French ambassador in Rome, calling the attention of the pontifical government to the consequences likely to arise from the publication of certain doctrinal decrees on the church and the Roman pontiff, the *schemata* of which had appeared in the Augsburg "Gazette." To this Cardinal Antonelli replied, March 19, that the proposed doctrinal decrees contained only a simple exposition of the fundamental principles on which the church reposes; that they had been again and again insisted on in preceding general councils; that they were especially developed in well known papal constitutions, &c. In the 36th general congregation, March 29, the *prooemium* and first chapter of the schema on faith were unanimously adopted in the form ultimately given to them by the deputation, and all the chapters were adopted before April 12, when the entire schema was put to the vote, every bishop rising in turn, and saying *Placet* or *Non placet*, or *Placet juxta modum* (this last formula implying that he dissented on a part of the matter decreed, or in the mode of formulating it); 595 prelates voted, of whom 515 voted *placet* and 80 *placet juxta modum.* The third solemn session was appointed for April 24. More than 100 amendments or modifications were submitted; but only two were adopted by the deputation on faith, and voted on in the general congregation of April 19. In the solemn session of April 24 the pope ordered that the proceedings should be made as public as possible; the doors of the council hall remained open throughout, and the partitions and enclosures concealing it from the crowd outside were temporarily removed. The constitution "On Catholic Faith," *Dei Filius*, was presented to the pope by Bishop Fessler, and read from the ambon. The vote being taken, 667 members answered to their names, all assenting to the constitution. The constitution "On Catholic Faith" purposes to affirm the existence of the supernatural revealed order, as opposed to rationalism and naturalism. The schema of a first constitution "On the Church" had been adopted by the "deputation on faith" long before the month of April. The theologians intrusted with its preparation had followed the method usually adopted in schools and works on theology; they had embraced all that relates to the institution of the church and its members, before treating of its head and the prerogatives and duties attached to his office. The outside pressure of the prevailing angry discussions caused the council to intervert this order, and to treat of the head of the church and his office from the very beginning. The opportuneness of a definition of the pontifical authority in teaching was deemed evident by the majority; and this once admitted, it became necessary to hasten the work while the council had not decreased in numbers, and before the oppressive heat of summer began. At this juncture the members of the council were divided on infallibility into three classes, the first in favor of an immediate discussion and definition, the second strenuously opposing the introduction of the question, and the third seeking a middle way by obtaining an indirect and implied definition through the condemnation of all errors adverse to the pontifical prerogatives. A *postulatum* in favor of this middle course had been drawn up before the opening of the council by Archbishop Spalding of Baltimore, and was favored by many American prelates; but it was never presented to the proper deputation, and its author and promoters soon joined the first class. Such an indirect definition was, however, perseveringly advocated throughout by Archbishop Darboy of Paris. The second class, or opposition proper, was led by Bishops Dupanloup of Orleans and Strossmayer of Bosnia and Sirmia. In the first class, forming the great majority in the council, there was no one leader. On April 29 the Italian bishops addressed to the council and the pope a collective letter, begging that all other matters should give way to the discussion on infallibility. The same day the deputation on faith referred the matter to the pope, who instantly ordered that the chapters "on the primacy and *magisterium* or teaching office of the Roman pontiff" should take precedence of all others. The discussion on the general question began May 14, and was concluded on June 3. It occupied 15 private sessions of four hours each, and was followed by the special discussion on each chapter, thus affording the opposition an opportunity for renewing their objections. On May 17 all the members of the council received an anonymous pamphlet addressed *Solis Episcopis* (to bishops only), and proposing the consideration of questions as to the sinfulness of concurring in a definition not clearly founded on Scripture and tradition. This, together with the publication in May of *Ce qui se passe au concile*, and toward the end of June of *La dernière heure du concile*, confirmed the determination of the majority. In the general discussion 65 members were heard, nearly all their discourses touching on the fourth chapter, that on infallibility; in the special discussion on the separate chapter, closed on July 4, 56 members spoke on this same subject, and 60 whose names were inscribed renounced their right to speak. More than half of the speakers were inopportunists. On July 11 the vote was taken on the amendments submitted in writing; and on the 13th the constitution *Pastor Æternus*, embodying the entire matter discussed, amended and adopted, was put to the vote in a general congregation. There were present 601 members, of whom 451 voted *placet*, 62 *placet juxta modum*, and 88 *non placet.* On July 15 a deputation composed of the primate of Hungary, the archbishops of Paris and Munich, and the bishops of Mentz and Dijon, had an audience of the pope, and demanded that the words *nixus testimonio ecclesiarum* should be inserted in the decree after the words *cum ex cathedra loquitur*, thus making the official infallibility depend on the previously ascertained testimony of each diocese. As the pope declined to entertain this demand, the prelates wrote him a joint letter, informing him that they persisted in their convictions, and begged permission to return home. On July 17 a letter to the pope, signed by 54 prelates, urged him to interfere at the very last moment and save the church from irreparable evils, by adjourning the council till October, and thereby postponing final action on the question of infallibility. This letter, believed by the signers to be confidential, was not intended for the pope, but was despatched in all haste and printed by the *Gazette de France* July 20, and by the Augsburg "Gazette" on the 22d. At the same time the *agence Havas* announced that the minority had drawn up a protest which was to be published outside of Rome. At the fourth solemn session, July 18, of 536 prelates present only two voted *non placet*, the others voting *placet;* 65 prelates absented themselves. Of the two dissenting bishops, one before leaving the council hall gave in his adhesion to the pope in person. Cardinals Rauscher, Schwarzenberg, Mathieu, and Hohenlohe, inopportunists, who were absent, immediately sent in their adhesion. All the other members of the minority accepted sooner or later the doctrine thus decreed. (See INFALLIBILITY, vol. ix., p. 265.) The rumor of the impending war between France and Germany made the members of the council anxious to return to their flocks. The pope authorized them to do so, with an injunction to return to Rome by Nov. 11. But the events following the capitulation of Sedan, the withdrawal of the French army from Rome, and the occupation of that city by the Italian government, induced the pope to publish, Oct. 20, the bull *Postquam Dei munere*, suspending indefinitely the sessions of the council.—See *Acta et Decreta Sacrosancti et Œcumenici Concilii Vaticani* (Freiburg, 1871); Cardinal Manning, "The Vatican Council and its Definitions" (London, 1871); and M. J. Chantrel, *Histoire du concile du Vatican* (2d ed., Paris, 1872).

VATTEL, Emmeric de, a Swiss publicist, born at Couvet, Neufchâtel, Aug. 25, 1714, died in Neufchâtel, Dec. 20, 1767. He was the son of a Protestant clergyman, and studied at Basel and Geneva. After residing some years in Geneva and Berlin, he received an office at Dresden in 1744; from 1746 to 1758 he represented Augustus of Saxony and Poland at Bern, and then became a privy councillor at Dresden, returning to Switzerland shortly before his death. He wrote in defence of the system of Leibnitz and on other subjects; but his principal work is *Le droit des gens, ou principes de la loi naturelle appliqués à la conduite et aux affaires des nations et des souverains* (2 vols. 4to, Neufchâtel, 1758), which has passed through numerous editions and has been translated into several languages. The best known English translation is that of Joseph Chitty, "Law of Nations, or Principles of the Law of Nature applied to the Conduct and Affairs of Nations and Sovereigns" (London, 1797, many times edited and reprinted in England and the United States). Vattel's last production was *Questions de droit naturel, et observations sur le traité du droit de la nature par M. le baron de Wolf* (Bern, 1762).

VAUBAN, Sébastien Leprestre, marquis de, a French military engineer, born near Saulieu, Burgundy, May 15, 1633, died in Paris, March 30, 1707. In 1651 he enlisted in the army of the prince of Condé, then in arms against the king. Returning to his allegiance, he was made a lieutenant, and in 1655 royal engineer; and during the war against Spain in Flanders he successfully conducted several sieges under Turenne. On the conclusion of peace in 1659 he was employed in improving and constructing fortresses, in which he displayed remarkable skill and originality. In 1667 he was wounded at the siege of Douai. During the invasion of Holland, he took Maestricht and other strongholds (1673–'5) by means of his new system of attack. In 1677 he won new laurels by his capture of Valenciennes and Cambrai. In that year he was made commissary general of fortifications, in which capacity he devised and nearly completed that strong line of fortresses which protects the frontiers and sea coasts of France. In the war against the league of Augsburg he took Philippsburg, Mannheim, Mons, Namur, and other towns (1688–'93). In 1699 he was elected an honorary member of the academy of sciences, and in 1703 was made marshal and conducted the siege of Breisach under the duke of Burgundy. During his military career he improved 300 old fortresses and built 33 new ones, conducted 53 sieges, and took part in 140 battles. His system of attacking a fortified place by regular approaches still practically prevails. As a civil engineer, he constructed the aqueduct of Maintenon, the mole at Honfleur, and several canals in the north and east of France, besides laying out and improving many seaports. Vauban wrote largely on a variety of subjects, and devoted much attention to political economy; but he published only his *Projet d'une dixme royale* (1707), a scheme for the collection from all classes, according to their means, of a single tax in lieu of all others, which the royal council ordered to be suppressed. His principal military writings, edited by Gen. de la Tour Foissac (3 vols., Paris, 1796), comprise his celebrated *Traité de l'attaque et de la défense des places* and *Traité des mines*, originally published at the Hague in 1737, and frequently reprinted separately. A new edition of his *Traité des sièges*, originally published in Berlin in 1747, appeared at Paris in 1829. Among his other works are selections from his manuscripts (the greater part of which has been lost) entitled *Mes oisivetés* (4 vols., Paris, 1843–'6).—See *Notice historique sur Vauban*, by De Chambray (Paris, 1845).

VAUCANSON, Jacques de, a French mechanician, born in Grenoble, Feb. 24, 1709, died in Paris, Nov. 21, 1782. He studied mechanics and anatomy for several years. The statue of the "Flute Player" in the gardens of the Tuileries first suggested to him the project of making an automaton player, and he acquired great celebrity by works of that class. (See AUTOMATON.) Cardinal Fleury appointed him inspector of silk manufactures, and in consequence of his improvements in machinery he was attacked by the workmen of Lyons; he retaliated by constructing an automaton ass weaving flowered silks. He bequeathed his collection to the queen, who gave it to the academy of sciences; it was scattered in consequence of a contest with the mercantile authorities for the possession of the manufacturing machinery, and Vaucanson's most celebrated automatons are now in Germany.

VAUCLUSE, a S. E. department of France, in Provence, embracing the ancient Comtat-Venaissin and the principality of Orange, and bordering on Drôme, Basses-Alpes, Bouches-du-Rhône, Gard, and Ardèche; area, 1,370 sq. m.; pop. in 1872, 263,451. The E. part is traversed by several offshoots of the Alps, the highest point reaching about 6,500 ft.; but in the west the surface is undulating, and there are considerable plains. The principal rivers are the Rhône, which flows on the W. boundary, and its affluents the Durance and Eygues. Iron ore, coal, and potters' clay are found, and there are mineral springs. Some 70,000 acres are occupied by vineyards, which yield a strong red wine of fair quality. The truffles produced are valued at about 4,000,000 francs annually. Silkworms, cattle, and sheep are largely reared. Silks, velvet, woollen cloths, linen, paper, iron, and perfumery are manufactured. It is divided into the arrondissements of Apt, Avignon, Carpentras, and Orange. Capital, Avignon.—The name Vaucluse ("enclosed valley") is derived from the fountain of Vaucluse, the source of the river Sorgue, in a cavern near Avignon. The valley of the upper Sorgue has been immortalized by Petrarch.

VAUD, or **Pays de Vaud** (Ger. *Waadt* or *Waadtland*), a S. W. canton of Switzerland, bounded N. by the canton and lake of Neufchâtel, E. by Fribourg, S. by the canton and lake of Geneva, and W. by France, from which it is separated by the Jura range; area, 1,244 sq. m.; pop. in 1870, 231,700, all Protestants except 17,592 Catholics and about 400 Jews. Capital, Lausanne. The highest Alpine points in the canton are in the S. E. part, and are connected by the Jorat, stretching N. of the lake of Geneva, with the Jura range in the west. The valleys of the latter are remarkable for rich pasture lands and for groves of walnuts. To the abundance of valleys (*vaulx*) is ascribed the origin of the name of the canton. The largest is that of Broye. Northern Vaud is drained by tributaries of the Aar and the lake of Neufchâtel, and southern Vaud belongs to the basin of the Rhône, its drainage flowing to that river and to the lake of Geneva. The latter lake is partly within the canton, and its E. shore is the warmest and most delightful portion. Among the other lakes is Lake Joux, about 3,300 ft. above the sea level and at the foot of some of the loftiest summits of the Jura, Mont Tendre S. E. of the lake being 5,500 ft. high. Southern Vaud is remarkably fertile, and produces excellent wine and fruit, which are largely exported. Large tracts of forest yield a great variety of trees. The salt mines at Bex are next to those of Basel the largest in Switzerland. Watches, musical boxes, tobacco, cigars, and carved wood are manufactured. The great concourse of visitors at Lausanne, Bex, Vevay, and other celebrated places, contributes greatly to the prosperity of the canton. Vaud forms part of *la Suisse romande* or *française*, and French, in a more or less correct form, is generally spoken. The canton is divided into 19 districts, comprising, besides the original territory between the lakes of Geneva and Neufchâtel conquered in 1536 by Bern from Savoy, the district of Bex and Aigle, S. E. of the lake of Geneva, and others on the lake of Neufchâtel, all of which were under Bernese authority till 1798, when with French aid they formed the republic of Leman; and by Napoleon's act of mediation (Feb. 19, 1803), the canton became part of the Helvetic confederation under its present name. The constitution of May 25, 1831, was revised in July, 1845, and thus adopted in August, after the overthrow in February of the local government, which had favored the Jesuits and the Sonderbund. The grand council is the supreme cantonal authority, and acts in conjunction with a council of state chosen by itself; but all laws initiated by the grand council, or proposed by it at the demand of at least 8,000 citizens, must be ratified by a popular vote. Another revision of the constitution in 1861 made it still more democratic.

VAUDEVILLE. See DRAMA, vol. vi., p. 244.

VAUDOIS. See WALDENSES.

VAUDREUIL, a S. W. county of Quebec, Canada, on the S. bank of the Ottawa river, at its entrance into the St. Lawrence; area, 182 sq. m.; pop. in 1871, 11,003, of whom 9,392 were of French, 570 of Irish, 565 of English, and 402 of Scotch origin. It includes Isle Perrot in the St. Lawrence, and is traversed by the Grand Trunk railway. Capital, Vaudreuil.

VAUDREUIL, a French Canadian family with several conspicuous members. **I. Philippe de Rigaud,** marquis de, born in France about 1641, died in Quebec, Oct. 10, 1725. He joined the king's musketeers, and in 1676 rose to the rank of brigadier. He came to America in 1687, served in Denonville's expedition against the Senecas and elsewhere, and obtained promotion. He was also in Frontenac's expedition against Onondaga in 1696, and was sent to ravage Oneida. In 1698 he became governor of Montreal, and in 1703 governor general of Canada. He warred against the Foxes, won the Iroquois to neutrality, baffled English influence in the west, and endeavored to save Acadia; and when Quebec was menaced by Sir Hovenden Walker's fleet he made vigorous preparations to repel him, and, aided by a storm which wrecked a part of the fleet, he was successful. **II. Pierre de Rigaud,** marquis de, fifth son of the preceding, born in Quebec, Nov. 22, 1698, died in Paris in 1764. He entered the military service, was governor of Three Rivers in 1733 and of Louisiana in 1742, and in 1755 was made governor general of Canada. After Braddock's defeat by Beaujeu he erected Fort Carillon, and garrisoned Forts Frontenac, Niagara, and Gaspé. Montcalm captured Oswego and Fort William Henry, and defeated Abercrombie; but the English gradually closed in upon the colony, and the French army was routed on the plains of Abraham. Vaudreuil endeavored to recapture Quebec, and gained one action, but being unsupported by the home government capitulated and went to France. An investigation justified his administration, but he died soon after. **III. Louis Philippe de Rigaud,** marquis de, nephew of the preceding, born in Rochefort, France, Oct. 28, 1724, died in Paris, Dec. 14, 1802. He entered the navy, commanded a vessel in the action between D'Estaing and Byron off Granada in 1779, and in that with Rodney off Martinique, April 17, 1780, and in other actions. He commanded a squadron in De Grasse's fleet in the action with Graves off the capes of the Chesapeake; and in the action with Rodney, April 12, 1782, he saved a part of the fleet, including all his own squadron, and sailed to Boston. He was a member of the states general in 1789, and in the night of Oct. 5–6 defended the royal family at Versailles against the mob. During the reign of terror he resided in England.

VAUGHAN, Henry, a British poet, born in the parish of Llansaintfread, Brecknockshire, South Wales, in 1621, died there, April 23, 1693. He studied at Oxford without graduating, was imprisoned for a time as a royalist, afterward studied medicine in London, and returned to his native place. He called himself the Silurist from the ancient inhabitants of South Wales, the Silures. His works are: "Poems, with the tenth Satyre of Juvenal Englished" (London, 1646); "Silex Scintillans, or Sacred Poems and Private Ejaculations" (part i., 1650; part ii., 1655; new eds., 1847, 1858); "Olor Iscanus" ("Swan of the Usk," a river near his birthplace), a collection printed by his brother (1651); two prose works, "The Mount of Olives, or Solitary Devotions" (1652), and "Flores Solitudinis, or certain rare and elegant Pieces" (1654); and "Thalia Rediviva: the Pass Times and Diversions of a Country Muse, in Divine Poems" (1678).

VAUGHAN, Robert, an English clergyman, born in 1795, died in June, 1868. He was educated for the ministry at Bristol college, was for six years pastor at Worcester, some years later was minister of the Independent chapel at Kensington, and afterward professor of ancient and modern history in University college, London. On the removal of the Independent college from Blackburn to Manchester, he became its president in 1843, at the same time filling the chair of theology. In 1857 he resigned on account of failing health. Soon after his removal to Manchester he projected the "British Quarterly Review," of which he was the editor from 1844 to 1867. Among his works are: "Life and Opinions of John de Wycliffe, D. D." (2 vols. 8vo, 1828), revised and published in one volume with the title "John de Wycliffe, D. D., a Monograph, with some Account of the Wycliffe MSS." (1853); "Memorials of the Stuart Dynasty" (2 vols. 8vo, 1831); "Causes of the Corruption of Christianity" (1834); "Thoughts on the Past and Present State of Religious Parties in England" (1838); "The Protectorate of Oliver Cromwell" (2 vols., 1838); "History of England under the House of Stuart" (2 vols., 1840); "History of Revolutions in England" (3 vols., 1859–'63); and "Memorial of English Nonconformity" (1865).

VAULABELLE, Achille Tenaille de, a French historian, born at Châtel-Censoir, Yonne, in October, 1799. He began life as a journalist, and in 1838 became an editor of the *National.* In 1835 appeared his *Histoire de l'Égypte moderne* from 1801 to 1833, and in 1844 his *Histoire des deux restaurations jusqu'à l'avénement de Louis Philippe* (3d revised ed., 8 vols., 1864). The provisional government of 1848 offered to send him as minister either to London or to Berlin, but he preferred to take his seat in the constituent assembly, and served on the committee for drawing up the new constitution and as chairman of that on education, and was minister of education from July to October. He opposed the policy of Louis Napoleon, and lost his seat in the elections of December, 1851. He has since written historical works on Louis Philippe's government, on the republic of 1848, and on the second empire.—His brother, ÉLÉONORE DE VAULABELLE (1802–'59), wrote *M. de Similor en Californie* (2d ed., 1856), and was a joint author of vaudevilles under the name of Jules Cordier.

VAUNKS. See CAPE RIVER.

VAUQUELIN, Louis Nicolas, a French chemist, born in Normandy, May 16, 1763, died Nov. 14, 1829. He was employed by an apothecary in Rouen previous to his removal to Paris in 1781, where he studied pharmacy, and became Fourcroy's assistant. After acting in 1793 as chief pharmaceutist in the military hospital at Melun, he became in 1794 inspector and professor of docimacy in the mining school of Paris, and then assistant professor of chemistry in the polytechnic school. On succeeding Darcet in the chair of chemistry at the collége de France, he became director of the new school of pharmacy, and subsequently professor of chemistry in the *jardin des plantes,* finally succeeding Fourcroy in the same capacity in the faculty of medicine. His discoveries, among which those of chromium and glucina deserve special notice, have been useful. He published several works on subjects connected with chemistry, and alone and jointly with Fourcroy made more than 200 contributions to periodicals.

VAUTIER, Benjamin, a Swiss painter, born in Geneva in 1830. He studied in Düsseldorf, and became known by admirable genre pictures relating to the domestic life of Switzerland and Swabia. Between 1858 and 1864 he exhibited "Devout Singers in a Church," "A Party embarking on a Rhine Steamer," "A Solitary Spinning Woman," "A Wife's Surprise on meeting her Husband in a Tavern on her way from Church," "A Sunday Afternoon in Swabia," and "Cats in a Criminal Case," one of his masterpieces. His "Courtier and Peasants in Würtemberg" (1865) appeared among his pictures at the Paris exhibition of 1867, where he received a medal. His subsequent productions comprise "The Antiquary among the Peasantry," "The Wake, or Feast after a Burial, in the Bernese Highlands" (1866), "The First Dancing Lesson in a Village of the Black Forest" (1868), "The Interrupted Quarrel" (1869), "Drinking the Bride's Health," "A Public Dinner," and "A Village Funeral" (1871). He has made designs for an episode of Immermann's *Münchhausen.*

VEDA, the general designation of the scriptures of the Brahmanic religion. The word means "knowledge," the Vedas being considered to contain the knowledge of all knowledge. The Veda texts or Veda Sanhitâs exist in four collections, Rig-Veda, Sâma-Veda, Yajur-Veda, and Atharva-Veda, for the general character and contents of which see INDIA, RELIGIONS AND RELIGIOUS LITERATURE OF. About the Vedas themselves clusters an immense religious literature. Among the earliest books written in explanation of the Sanhitâs are the Brâhmanas, which are mostly confined to descriptions of the ceremonies prescribed, and relate numerous legends bearing on them. Collections of practical rules regarding matters of worship were also made; these are called Sûtras. Vedângas, or members of the Vedas, comment upon the language, mythology, and astrology of the Sanhitâs; and the Vedântas, or purpose of the Vedas, are philosophical disquisitions on the Brahmanic religion. The word *shastra* (*s'astra*) is often added to these terms, as Vedânta-shastra. *Shastra* signifies treatise, book, precept, and hence Vedânta-shastra is a work on the Vedânta philosophy or the whole body of teaching on that subject.—The four hymn texts of the Vedas have all been published in Europe, the Rig-Veda in three different forms. Of the Rig-Veda, Langlois has published (Paris, 1848-'51) a very poor French translation; Wilson's (London, 1850-'57, continued and to be completed by Cowell) is better, but represents the commentators rather than the hymns themselves. Müller has published (1869) the first volume of a fully annotated version, but it contains only 12 hymns. Benfey has translated about 130 hymns in the *Orient und Occident.* J. Muir's "Original Sanskrit Texts" (5 vols., London, 1863-'70) gives the transliterated texts and literal version of a great many hymns and parts of hymns. A German translation of the Sâma-Veda accompanies Benfey's edition (Leipsic, 1848). Two books of the Atharva-Veda are rendered into German by Weber, in his *Indische Studien.* The most important Brâhmanas have also been published: the Çatapatha by Weber; the Aitarêya by Haug (Bombay, 1863, with translation); the Taittirîya by Mitra (Calcutta); the principal Upanishads, with commentary and translation, in the *Bibliotheca Indica* at Calcutta.—For the Vedas in general, see Colebrooke's essay in the "Asiatic Researches," vol. viii., and in his collected essays (2d ed., with detailed notes by W. D. Whitney); Roth, *Zur Literatur und Geschichte des Veda* (Stuttgart, 1846); Weber, *Indische Literaturgeschichte* (Berlin, 1852); Barthélemy Saint-Hilaire, *Des Védas* (Paris, 1854); Max Müller, "History of Ancient Sanskrit Literature" (London, 1859); and W. D. Whitney, in the "Journal of the American Oriental Society," vols. iii. and iv., and in "Oriental and Linguistic Studies," vol. i.

VEDDER, Elihu, an American artist, born in New York in February, 1836. He studied under Matteson, spent several years in Italy, and afterward opened a studio in New York and devoted himself to genre painting. He subsequently returned to Europe, and now (1876) resides in Rome. Among his best pictures are "The Lair of the Sea Serpent," "The Arab Listening to the Sphinx," "St. Simeon Stylites on his Pillar," and "The Monk upon the Gloomy Path."

VEGA, Garcilaso de la. See GARCILASO DE LA VEGA.

VEGA, Georg von, baron, a German mathematician, born at Sagoritza, a village in Carniola, in 1756, murdered in 1802. He studied in Laybach, joined first the navy, then the army, and in 1784 became a military instructor in mathematics. He distinguished himself in the wars against the Turks and the French, and was ennobled in 1800. His dead body was discovered in the Danube, Sept. 26, 1802, and 30 years later it was brought to light that he had been thrown into the river by a miller while walking on its bank. His *Vorlesungen über die Mathematik*, *Logarithmisch-trigonometrisches Handbuch*, *Thesaurus Logarithmorum completus*, *Anleitung zur Zeitkunde*, *Natürliches Mass-*, *Münz- und Gewichtssystem*, and *Logarithmentafeln* have been many times republished; the last named work reached in 1876 its 57th edition.

VEGA, Lope de (LOPE FELIX DE VEGA CARPIO), a Spanish dramatist, born in Madrid, Nov. 25, 1562, died there, Aug. 26, 1635. Shortly before his birth his father had removed to the capital from his ancestral domain of Vega, in the valley of Carriedo, and died while his son was very young. His uncle, the inquisitor Miguel de Carpio, enabled him to cultivate his extraordinary and precocious faculties at the royal college; and after an escapade from that institution, during which he served against the Portuguese, he was patronized by the bishop Manrique of Àvila. He took his bachelor's degree at Alcalá, became secretary to the duke Antonio of Alva, and married Isabel de Urbino, daughter of the king-at-arms. He was imprisoned on account of a duel and then exiled from Madrid, spent several years in the celebrated literary circles of Valencia, and became a widower in less than a year after his return. In 1588 he joined Philip II.'s armada against England. Shortly before his second marriage in 1597 with Juana de Guardio, he held for the last time a secretaryship, under the same marquis of Sarria who as count de Lemos became known as Calderon's munificent patron. His domestic happiness was after several years interrupted by the death of a son, and of his wife in giving birth to a daughter. After an illicit alliance with Maria de Luxan, who bore him a son who died early and a daughter who became a nun, he joined a lay religious body, and in 1609 became a priest; in 1610 he joined the same brotherhood to which Cervantes afterward belonged, and in 1625 entered a congregation at Madrid, which in 1628 elected him chief chaplain. As early as 1609 he had styled himself a servant of the inquisition (*familiar del santo oficio*), and he produced most of his pieces during his connection with the church. Hypochondria imparted to his last religious poems a melancholy degree of fanaticism, and on his deathbed he deplored that he had ever been engaged in other than religious occupations. He left his manuscripts to his especial patron the duke of Sessa, who provided for his funeral, which lasted nine days. His fertility and rapidity of execution were fabulous. He wrote about 1,800 plays, besides hundreds of *autos*. About 300 of the former are contained in 28 volumes (1604–'47), and 112 in *Comedias escogidas*, edited by Hartzenbusch in the *Biblioteca de autores españoles*. His intense patriotism, faithful delineation of popular life, and admirable versification made him exceedingly popular, although he disregarded all sense of propriety and of chronological accuracy in his effort to produce an interesting plot. His dramatic genius embraced the whole range of the art. He first divided the secular from the religious drama, and introduced other modifications and improvements in the stage. Among his best known pieces are *Los tres diamantes*, *La fuerza lastimosa*, *La discreta enamorada*, *La dama melindrosa*, and *El padre engañado*, the last adapted to the English stage by Holcroft ("The Father Outwitted"). His epic poems were soon forgotten, but among his innumerable minor poems are several of superior merit. A select edition of his prose and poetry appeared at Madrid in 1776–'9 (21 vols.), and Hartzenbusch has edited his *Obras no dramáticas* in the above mentioned collection (1856).—Among the Spanish authorities on Lope de Vega are his friend Montalvan and Navarrete; in English, Southey, Lord Holland, and especially Ticknor in his "History of Spanish Literature."

VEGETABLE IVORY TREE. See PHYTELEPHAS.

VEHMIC COURTS (Ger. *Vehmgerichte* or *Femgerichte*, from old Ger. *Fem*, punishment, and *Gericht*, tribunal), secret tribunals which flourished chiefly in Westphalia during the middle ages. They are not mentioned by name before the 13th century, but there are some traces of their existence in the 12th, and as some historians believe even in the 9th century. Westphalia was the home of these courts, and only upon the "red earth," as its soil was called in Vehmic phraseology, could their members be initiated or their sittings be held. The tribunals were at first a protest against the arbitrary decisions of the lawless barons and nobles. The emperor and the nobles of his court, and with them men of all ranks, associated themselves together for the formation of free tribunals (*Freigerichte*), composed of elected "free judges" (*Freischöffen*, or *Freischöppen*), to try persons accused of crimes against persons or property. They were bound by solemn oaths not to reveal the circumstances of the trial or the sentence passed on the offender if found guilty; and in order to be one of the brotherhood, the applicant must be of good reputation, and must have two sureties who were already free judges. The initiated recognized each other by signs. The courts might be summoned at any time and in any place in Westphalia, in public or private buildings, in the forests or caves, or in the open fields; they were sometimes held publicly, in the presence of the people, but usually they were closed against all but the initiated and the accused person. The emperor, or in his absence the count or noble of highest dignity, presided, though in some instances men of common birth sat as chief judges, even when those of higher rank were present. If any uninitiated person intruded, he was immediately put to death. Before the chief judge lay the emblems of his authority, the sword and the cord. In the early history of the organization, the accused could be absolved by taking a solemn oath of purification upon the handle of the judge's sword; but when at a later period it was found that criminals did not hesitate to perjure themselves, the accuser, always a free judge, could substantiate his charge even against the oath of the accused by three or more witnesses. If the accused could rebut these by a number one half greater, he was still discharged; but if condemned, sentence was passed upon him, and he was forthwith hanged. If the person accused had not been arrested, he was summoned to appear by fastening upon his door or gateway the summons of the Vehmic court, enclosing in it a small coin. If he had no known or certain residence, then these written summonses were posted at the crossing of four roads nearest his haunts. If he failed to appear or to send a messenger, he was condemned as despising the jurisdiction of the holy Vehm, and once condemned there was little chance of his life while he remained in Germany. In the 14th and 15th centuries the free judges were more than 100,000 in number, scattered over every part of Germany. The condemnation of an offender by a Vehmic court was known to the whole brotherhood in a very short time; and if it were the father, brother, or son of one of the initiated who was condemned, he not only might not warn him of his danger, but was bound to aid in putting him to death under penalty of losing his own life. When slain he was to be hanged on the nearest tree, nothing of value which he might have about him being removed, and a knife being thrust into the earth near him as an indication that his death was the result of a sentence of the Vehmic court. A power so formidable, and exercised under such obligations of secrecy, soon raised the hostility of those who feared becoming its victims, as well as of those who saw in it an engine capable of terrible oppression. In 1371 the emperor Charles IV., in an instrument known as the public peace or pact of Westphalia, stipulated for the recognition of the Vehm; but in the next century the number of its opposers greatly increased, and in 1461 an association was formed among the cities and princes of Germany and the cantons of Switzerland to resist the free judges, and to require that the trial of accused persons should take place in open day. In 1495 Maximilian I. established a new criminal code, which materially weakened the power of the Vehmic courts; and in the 16th century they were but seldom held. The last public sitting was in 1568, near Celle; but there were secret sittings of the court in the 17th and 18th centuries, and according to Kohlrausch even as late as 1811, in Münster. But they ceased to excite terror or to exert any considerable influence before the close of the 17th century.—Kopp, *Verfassung der heimlichen Gerichte in Westphalen* (Göttingen, 1794); Hutter, *Das Vehmgericht des Mittelalters* (Leipsic, 1798); and Wigand, *Das Vehmgericht Westphalens* (Hamm, 1825).

VEHSE, Karl Eduard, a German historian, born in Freiberg, Saxony, Dec. 18, 1802, died near Dresden in June, 1870. From 1825 he held office in the department of archives at Dresden, and became its chief in 1833. In 1828 appeared his *Geschichte Kaiser Otto's des Grossen* (2d ed., 1865), and in 1834 his *Tafeln der Welt- und Culturgeschichte.* He accompanied the separatist Stephan to the United States about the beginning of 1839, but returned home at the end of that year, and after travelling in Europe settled in Berlin. He was imprisoned six months and expelled from Prussia for disparaging the royal family in his *Geschichte der deutschen Höfe seit der Reformation* (48 vols., Hamburg, 1851–'8; partly translated into English by Demmler, 1854–'6). He became a naturalized Swiss in 1857, and during his last years lived alternately in Italy and Saxony.

VEII, one of the 12 cities of the Etruscan confederation, the largest and most powerful of all, on the Cremera, a small affluent of the Tiber, near the present town of Isola Farnese, about 10 m. N. N. W. of Rome. Its territory seems to have extended from the mouth of the Cremera to the Ciminian forest, and from Mt. Soracte to the Tyrrhenian sea. Veii was a great city long before the foundation of Rome, and was for centuries her rival in power, until it was destroyed about 396 B. C. by the Romans under Camillus. When soon after Rome was destroyed by the Gauls under Brennus, the Roman people were prevented by Camillus from removing to Veii and rebuilding it instead of their own city. It was repeopled under Augustus, but relapsed into decay, and disappeared from history.

VEIN, in mineralogy. See MINERAL DEPOSITS.

VEINS, the name applied to four systems of blood vessels, differing in structure, course, and function, and having in common only the character of conveying blood toward and not from the heart. These systems are the common systemic, the portal, the pulmonary, and the umbilical, the first two circulating impure or venous, and the last two pure or arterial blood. As to the special anatomy of the general venous circulation, it will be sufficient to say here that all the veins from the lower limbs and the pelvic and abdominal organs carry their contents into the inferior vena cava, and those of the head, upper limbs, and thorax into the superior vena cava; that these two great vessels pour their blood into the right auricle of the heart, whence it enters the right ventricle, to be sent by this through the pulmonary artery to the lungs for purification, returning arterial by the pulmonary veins to the left auricle, and thence by the left ventricle and aorta over the body.—The principal superficial vein of the side of the neck is the external jugular, in which venesection is occasionally performed; it is very conspicuous in some persons during violent agitation of body or mind. The deep-seated internal jugular, by the side of the carotid artery, receives the blood from the sinuses of the brain; the median basilic at the bend of the elbow is the classical one for venesection, being very accessible and of considerable size; the longest vein in the body is the internal saphena, extending from below the ankle joint to within about an inch of the groin; the other veins as to their course generally follow the arteries; the heart has its own system of veins, not communicating with the venæ cavæ, but opening directly into the right auricle. These systemic veins, as they are called, correspond to the branches of the aorta, and grow larger and larger toward the heart. The portal veins collect the blood from the small vessels of the abdominal viscera into one, the vena portæ, which subdivides like an artery within the liver. In the pulmonary circulation, by a contradiction in terms, the vessel called the artery carries venous blood, and the veins arterial blood.—Veins are generally thinner, less elastic, and of larger calibre than the corresponding arteries, and are provided with membranous folds or valves to prevent a backward flow of the blood. In vertebrates generally they consist of an external fibrous and areolar coat, a middle or muscular, and an internal fibrous lined with fenestrated or striated membrane and epithelium. Venous capillaries do not essentially differ from arterial, consisting of tubes of homogeneous membrane, with a few oval nuclei; the veins of the brain have no muscular coat; at their junction with the heart they are more muscular, thicker, and red, from a prolongation into their structure of the muscle of the auricle, and they have also a partial investment of the serous layer of the pericardium; where the vena cava pierces the diaphragm it has a covering of fibrous tissue; the cerebral veins or sinuses are tubular excavations in the substance of the dura mater, lined with the usual internal membrane; the umbilical vein is smooth, without valves, lined with epithelium, and composed of a thick fibrous mass. Veins have their nutrient vessels, and a very few nerves. The venous system is far more extensive than the arterial, both in the size and number of the vessels and their branches. The veins arise in the capillaries, increasing in size and diminishing in number toward the heart. (See Capillary Vessels.) The veins which return the blood from some of the erectile tissues were thought at one time to begin in little sacs, into which arteries much larger than capillaries open; but recent investigations have shown that the appearances were deceptive, and that, although the capillary system of erectile tissue is peculiar, having tortuous enlargements and *lacunæ*, the ordinary arrangement of direct passage from arteries to veins through the capillaries exists. Veins intercommunicate very freely, forming networks and plexuses, the most remarkable of which in man are those about and within the spinal canal. The veins are passive organs, determining by the contraction of the muscles the course of the blood; they are also reservoirs for the circulating fluid, and active agents in absorption; as reservoirs, though very important in man, they are most remarkable in the lower animals, as in seals, whales, and many diving birds.—The valves in veins are interesting not only as specimens of animal mechanics, but as having in a great degree suggested to Harvey the discovery of the circulation of the blood; these are raised portions or pockets of fibrous membrane lined with epithelium, very delicate, and in the most perfect semilunar shape; there are generally two together in the larger vessels, opening toward the heart, and when in contact completely preventing the regurgitation of the blood; at the orifices of the smaller veins they are often single, and in the great vessels of the larger mammals frequently three; there are none in the capillaries, though they exist in veins of half a line in diameter; they vary from a mere linear elevation to a deep pocket. Their situation is irregular, and their number not very great; in man they are found in veins subject to muscular pressure, and are therefore most numerous in the limbs; in the head and neck there are but two, in the external jugular, and these not very perfect; in the arm they are most numerous at the upper part, with none in the subclavian, innominata, and superior cava; in the legs they are most abundant at the lower part; there are none in the spinal veins, in those of the portal and hepatic systems, in the heart, kidneys, uterus, and lungs, as a general rule; they are few in cetaceans and birds, and almost absent in reptiles and fishes.—Veins are more subject to diffuse inflammation than arteries, and, from their active absorbent powers, morbid materials are carried rapidly and widely over the system from the heart. Phlebitis, or inflammation of their lining membrane, is a dangerous and common disease, sometimes leading to fatal purulent absorption, and frequently to obliteration of the vessel. Varix or dilatation of a vein, from the comparatively small amount of circular fibres, is one of the most frequent of the morbid conditions of the body. (See Varicose Veins.) Small earthy concretions are not unfrequently deposited in the walls of veins from the blood; they are named phlebolithes or vein stones, and consist chiefly of phosphate and carbonate of lime. Entozoa are often found in the interior of the veins in the lower animals. A vein if wounded, either accidentally or in venesection, heals readily, without interference with its functions; but a wound in the axillary, subclavian, or lower part of the internal jugular, during a surgical operation, may prove suddenly fatal from the sucking in of air and a consequent instantaneous paralysis of the heart's action.

VEIT, Philipp, a German painter, born in Berlin, Feb. 13, 1793. His mother was the daughter of the philosopher Mendelssohn, who after the death of her first husband married Friedrich Schlegel. He completed his studies in Rome, where he was associated with Cornelius, Overbeck, and other German painters in the attempted revival of mediæval art; and he executed in the villa of the Prussian consul, J. S. Bartholdy, the fresco representing the "Seven Years of Plenty," as a companion piece to Overbeck's "Seven Years of Famine." In 1826 he became director of the Städel art institute at Frankfort, and produced works in oil and fresco, which are among the most characteristic productions of modern German art. His masterpiece is a fresco in the institute representing "Christianity bringing the Fine Arts into Germany." Such was his dislike of the new realistic school, that on the purchase in 1843 of Lessing's "Huss before the Council of Constance" for the institute, he resigned his office, and settled in Sachsenhausen, opposite Frankfort. Among his subsequent productions are an "Assumption of the Virgin" for the Frankfort cathedral, and "The Marys at the Sepulchre," "The Parable of the Good Samaritan," and "The Egyptian Darkness," for the king of Prussia.

VELA, Vincenzo, an Italian sculptor, born at Ligurnetto, in the Swiss canton of Ticino, in 1822. He was brought up as a stone cutter, but perfected himself in Milan as a sculptor, and in 1844 won a competitive prize at Venice. After his return from the Italian war against Austria (1848) he refused to join the academy of fine arts at Milan, and settled in Turin. His works include statues representing "A Prayer," "Spartacus," "Hope and Resignation," "Music in Tears" (for Donizetti's funeral monument at Bergamo), "France and Italy" (a group presented in 1863 by the ladies of Milan to the empress Eugénie), and "Columbus and America" (a colossal group in plaster). His masterpiece, representing the last days of Napoleon at St. Helena, attracted much attention at the Paris exhibition of 1867, and is now in the metropolitan museum of art, New York.

VELASQUEZ, Diego Rodriguez de Silva y, a Spanish painter, born in Seville in June, 1599, died in Madrid, Aug. 7, 1660. He was of Portuguese origin on the father's side. While a child he studied under the elder Herrera, whose harshness caused him to enter the school of Francisco Pacheco, but with little advantage excepting his marriage with his master's daughter; and he was in reality self-taught. His chief model was a peasant boy, whom he painted in his rags in every variety of expression and attitude; and he also excelled in painting fruit, fish, and other common objects of still life. His works of this period exhibit great breadth and force, but no attempt at ideal or poetical expression. A well known specimen, "The Water Carrier," is in the collection at Apsley house, London. In 1622 he went to Madrid, and in 1623 was employed to paint the portrait of Olivarez, the minister of Philip IV. The king was his next sitter, and the picture was exhibited on the steps of the church of San Felipe, and greatly admired. Velasquez was immediately appointed court painter, with a regular salary in addition to the payments for his works, and is said to have received the exclusive privilege of portraying the king on canvas. In 1627 his "Expulsion of the Moriscoes from Spain" gained him the appointment of usher of the chamber. He became intimate with Rubens during that artist's embassy at Madrid. From 1629 to 1631 he was in Italy, and studied diligently the works of Raphael, Michel Angelo, and the other great masters; but the two works which he sent home from Rome, "Jacob with the Garment of Joseph" and "Apollo at the Forge of Vulcan," exhibit no trace of Italian influence. On his return to Spain, Philip established him in the palace, and sat to him for a celebrated equestrian portrait. In 1648–'51 he was again in Italy, to collect pictures and statuary for the king, and while in Rome painted a portrait of Innocent X. Subsequent to his return to Madrid he produced some of his finest works, including the celebrated *Meninas*, representing the infanta Margarita and her maids of honor, which, in respect to aërial and linear perspective, local color, and animal and human life, is held to be almost unrivalled. In 1652 he received the exalted post of *aposentador mayor* (chief chamberlain), which required him to be constantly in attendance on the king, and interfered with his painting. In the spring of 1660, while engaged in arrangements for the royal family at the isle of Pheasants, on the frontiers of France, he was seized with a tertian fever, of which he died. His wife died of grief a week afterward.—Owing to the fact that Velasquez painted almost exclusively for the king, and that his pictures, being royal property, were generally respected by Napoleon's commanders, he is still to be seen to advantage only in Madrid. The royal gallery there contains about 60, comprising portraits, history, genre, and landscape, in all of which he was equally great. In delineations of female beauty, and in subjects demanding an elevated ideal or poetical treatment, he was less successful; and his pictures of this class, although powerful, are inferior to those of Murillo. His "Surrender of Breda" or *Las lanzas* ("The Lances"), remarkable for the feeling and expression of the figures and the technical execution, was etched in 1875 by the French artist Laguillermie. Of his genre pictures, the celebrated group entitled *Los bebedores* ("The Drinkers") is regarded for its humor alone as entitling Velasquez to the name of the "Spanish Hogarth."—See Sir William Stirling (Maxwell), "Annals of the Artists of Spain" (3 vols., London, 1848), and "Velasquez and his Works" (1855).

VELDE, Franz Karl van der, a German novelist, born in Breslau, Sept. 27, 1779, died there, April 6, 1824. He held judicial offices in various places, and wrote poems and plays, but was chiefly known by his novels, the principal of which are *Guido*, *Die Eroberung von Mexico*, *Die Malteser*, *Die Wiedertäufer*, *Arwed Gyllenstierna*, and *Christine und ihr Hof.* His complete works have been published in 27 vols. (Dresden, 1830–'32).

VELIA, or **Elea,** an ancient Greek city on the W. coast of southern Italy, believed to have been settled by Ionian colonists from Phocæa about 544 B. C. Like their compatriots in Massilia, they were celebrated for commercial enterprise. The city was the birthplace of the philosophers Parmenides and Zeno, the disciples of Xenophanes of Colophon, and with him founders of the Eleatic school of philosophy. (See ELEATIC SCHOOL.) Under the Roman republic it was mainly noted as a pleasant resort on account of its fine climate. It was an episcopal see from the early ages of Christianity till the end of the 6th century. Its subsequent destruction has been ascribed to the ravages of the Saracens during the 8th and

9th centuries. The ruins of Velia are on a low ridge about 1½ m. from the mouth of the Alento (anc. *Hales*), in the province of Principato Citeriore and ½ m. from the coast. A mediæval castle and the village of Castellamare della Bruce or Brucea mark the site of the ancient city. Excavations were undertaken here in 1874 by Salazaro.

VELLEIUS PATERCULUS. See PATERCULUS.

VELLETRI (anc. *Velitræ*), a town of central Italy, at the foot of Mt. Artemisio, in the province and 20 m. S. E. of the city of Rome; pop. about 13,000. It has a fine cathedral and several public and private palaces. Wine and olives abound in the vicinity. Originally it was a Latin or Volscian city of considerable importance. According to inscriptions described by Cardinali (Rome, 1823), it had an amphitheatre and fine temples. Garibaldi defeated the Neapolitans here in March, 1849. Velletri was the capital of a papal delegation till 1870, when it was incorporated with the kingdom of Italy.

VELLORE, a town of British India, in the district of North Arcot, Madras, on the S. side of the river Palar, in lat. 12° 55′ N., lon. 79° 11′ E., 79 m. W. S. W. of the city of Madras, and 16 m. W. of Arcot; pop. about 50,000. It is tolerably clean and well built, a place of considerable trade, and a station on the railway from Madras to the W. coast. About a mile N. of the town is an extensive fortress. In the public square there is a fine Hindoo pagoda, built about four centuries ago. The climate is intensely hot, but healthful.—Vellore was founded by the rajah of Bijanagur in the latter part of the 15th century. Sevajee took it from his descendants in 1677; and it fell into the hands of the British when they obtained possession of the Carnatic. On the fall of Seringapatam it was selected as the residence of the sons and family of Tippoo Sultan. On July 10, 1806, the sepoys rose in mutiny at Vellore and killed 13 officers and 100 men of the European garrison.

VELLUM. See PARCHMENT.

VELOCIMETER, an instrument for measuring the velocity of projectiles. Prior to 1840 such measurements were made by suspending a gun in a pendulum, and observing the arc described in its recoil. This gave the means of computing the velocity imparted to the projectile, with a probable error of a very few feet per second. In 1840 Wheatstone suggested the use of electricity for obtaining the data required for the computation, and for a quarter of a century it has been used exclusively. The velocity of a moving body becomes known when we know the time it takes to pass through a measured portion of its path. The space is determined by merely choosing certain points (usually about 100 ft. apart) in the path of the projectile, and measuring the distance between them. The time required to pass over this distance therefore becomes the sole object of inquiry; and a velocimeter is merely an instrument for measuring with extreme accuracy small intervals of time. To accomplish this, a screen of fine wire carrying an electric circuit is placed at each end of the measured interval, in such manner that the passing projectile shall rupture the two circuits, and the two ruptures instantly telegraph themselves to a machine, which records them in such a way that the interval of time between them can be immediately read. The recording instrument is called a chronograph. The number and variety of chronographs are very great, but they all involve one mechanical principle, viz.: the records must be made by means of parts of the machine moving at rates which are known with great exactitude, during intervals which begin and terminate with the two ruptures respectively. This may be illustrated by the following contrivance, which is a modification of the Navez chronograph by Col. J. G. Benton of the United States ordnance department. It consists of a vertical metallic semicircle, *b*, graduated with the ordinary circular units and supported upon a bed plate, *a*. Two pendulums, *p p′*, are swung upon the axis of the arc, and have their mass so distributed that their times of oscillation are equal. When deflected in opposite directions from a vertical position to 90°, they touch the magnets *m m′*, which hold them in the new or horizontal position. The magnets are excited by circuits, *c c*, *c′ c′*, which pass through the wire screens in front of the gun. If they were both ruptured at the same instant (the instrument being perfectly adjusted), the pendulums would be simultaneously released, and would pass each other opposite the zero mark at the lowest point of the graduated arc; but being ruptured successively, they pass at some point more or less distant from it, this distance being dependent upon the length of the interval of time between the two ruptures. To mark the point where this passage occurs, a stud, attached to the pendulum *p*, strikes the oblique head of a pin attached to a lever in the other pendulum, and causes it to make an indentation or an ink mark upon a piece of paper clamped to the graduated arc, leaving a record of the angle of deflection of the two pendulums at the instant of passage. By a simple formula the interval between ruptures can be computed from this angle.—A very simple form of velocimeter, probably used more extensively than

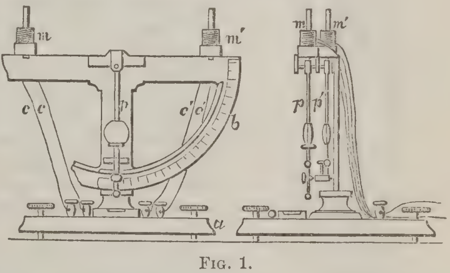


FIG. 1.

any other, is that invented by Capt. Le Boulengé of Belgium. A metallic standard, S, fig. 2, sustains two electro-magnets, A B. The magnet A, when excited, holds a bar C as its armature, called the "chronometer." A zinc tube, D, removable at pleasure, fits over the latter. The magnet B holds a smaller armature, F, called a "registrar;" and immediately beneath it is an apparatus, L, holding in tension a cocked main spring, which carries a knife edge. After the relative altitudes of the two magnets have been adjusted, the knife edge is caused to make an indentation upon the zinc tube of the chronometer for a zero mark, and then the machine is ready for the record. The magnet holding the chronometer is excited by the circuit through the screen nearest to the gun, and the registrar magnet by the other circuit. When the first is ruptured the chronometer falls; when the second is ruptured the registrar falls, springing the knife edge and causing a cut to be made in the zinc tube. The space between this cut and the zero mark gives, by the formula for falling bodies, the time interval between the two ruptures.—The two machines described are capable of showing the velocities of projectiles with great precision, their mean errors not exceeding $\frac{1}{10,000}$ of a second. Col. Benton has used his machine without the aid of electricity. In place of electro-magnets to hold the pendulums and release them, he has employed springs kept tense by means of cotton threads. The threads, being ruptured by the passing shot, release the springs, which dismiss the pendulums. The results so obtained are but little less accurate than those with electro-magnets. Velocimeters are also used for obtaining data by which the resistance of air to the motion of projectiles may be determined. There is no known method of computing it, and the only resource is to measure it directly. This the velocimeter enables us to do by showing how much a projectile is retarded in passing over a series of intervals. But for each set, and for each velocity, a separate trial must be made. The determination of the velocity through a succession of intervals requires a chronograph of much more complicated structure than the simple ones described, for it must record the times of rupture of half a dozen circuits, or of half a dozen ruptures of the same circuit. Usually the screens are all placed in the same circuit, which renews itself after each rupture, before the shot reaches the next screen. The recording device consists of a cylinder or disk revolving at a known rate, and receiving at the instants of rupture some visible marks from a stationary device or tracing point controlled by the current. The most ingenious application of the velocimeter yet made is the measurement of the varying velocity of a projectile in the bore of a gun, which has been accomplished by means of a special apparatus devised by Capt. W. H. Noble of the British army, and also by a series of Le Boulengé chronographs.

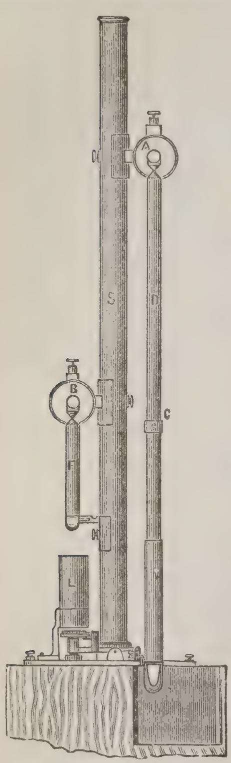

FIG. 2.

VELOCIPEDE (Lat. *velox*, swift, and *pes*, foot), a light carriage so constructed that it may be swiftly propelled by the feet of a person mounted upon it. In its earliest form it was invented at Mannheim in 1817 by Karl von Drais, and called a *draisine*. As then constructed, it consisted of a bar about 5 ft. long and 6 in. wide, supported at each end upon a single wheel, the front one being so attached that it could be turned to the right or left like the front wheels of an ordinary carriage. The rider sat astride of the bar and propelled himself and the machine by the action of his feet upon the ground. The vehicle in that form did not come into use, but about 1867 it was improved and became a favorite with amateur gymnasts. A saddle was fixed upon the longitudinal bar, and a foot crank was placed upon each side of the forward wheel to serve for propulsion. The machine is kept in position by the action of the rider's body and limbs, and also by its own momentum in a certain plane. As recent examples of rapid riding the following may be cited: 1 mile in 3 minutes, by J. Keen in a match with Frederick Cooper for the championship at Queen's grounds, Sheffield, England, Sept. 18, 1875; 50 miles in 3 h. 9 m. 21 s., by J. Keen at Molineux grounds, Wolverhampton, Nov. 30, 1874, including stoppages; 100 miles in 7 h. 35 m. 43 s., by David Stanton, at Lillie Bridge grounds, Oct. 19, 1874; 132 miles in 17 h. 15 m., by J. T. Johnson, including all stoppages, from London to Worthington and back.

VELPEAU, Alfred Armand Louis Marie, a French surgeon, born at Brèche, department of Indre-et-Loire, May 18, 1795, died in Paris, Aug. 24, 1867. He was brought up to assist his father, who was a farrier, learned almost without assistance reading, writing, and some of the rudiments of medicine, acquired reputation among the peasantry by several cures, and was enabled by a neighbor to study in the hospital of Tours, where he graduated in 1823. In 1830 he became surgeon to the *Pitié* hospital at Paris, in 1832 a member of the academy of medicine, in 1835 professor of clinical surgery, and in 1842 successor of Larrey in the institute. His clinical lectures at the *Charité* hospital were among the most remarkable of his claims to distinction. His works include *Traité de l'anatomie chirurgicale* (2 vols., 1825); *Anatomie des régions* (1825–'6; revised and republished under the title *Anatomie chirurgicale générale et topographique*, 2 vols. 8vo, 1838; 2d ed., by Velpeau and Béraud, 1862); *Mémoire sur les positions vicieuses du fœtus* (1830); *Recherches sur la cessation spontanée des hémorrhagies traumatiques primitives et la torsion des artères* (1830); *Nouveaux éléments de médecine opératoire* (1832), a work of the highest authority; *Embryologie ou ovologie humaine* (1833); *Des convulsions, pendant la grossesse, durant le travail, ou après l'accouchement* (1834); *Leçons orales de clinique chirurgicale*, collected by Jeanselme and Pavillon (3 vols., 1840–'41); and *Traité des maladies du sein et de la région mammaire* (1853). His last work was the article *Adénite* in the *Dictionnaire encyclopédique des sciences médicales* (1865).

VELVET (Lat. *vellus*, a fleece), a textile fabric woven wholly of silk or of silk and cotton mixed, having a loose pile or short shag of threads on the surface, which give it a fine soft nap. Cotton stuffs manufactured in the same way are commonly called velveteens. This manufacture appears to have originated about the 13th century, and was limited for a long time to the Italian cities. It thence passed into France, where it was greatly improved, and in 1685 was introduced into England by French refugees. Velvet is very durable, from the close texture of the under side, and also from the thick nap of the upper, which opposes great resistance to external friction. It is moreover very warm, and suitable for rich ornamental figured work. Its peculiar character is derived from the insertion of short pieces of silk thread, secured under the shoot, weft, or cross threads, their ends standing upright and so closely together as to conceal the interlacing of the threads beneath. They are furnished in an extra set of threads, called pile threads, arranged in the loom parallel to the warp threads, and much longer than these, which in the progress of the weaving are passed, after every third throw of the shuttle, over a thin, semi-cylindrical, straight brass wire, which is laid across the whole fabric over the warp threads. The next working of the treadle carries the pile threads down over the wire, when they are covered and fastened by the next throw of the shuttle. Another wire is placed in the same position for the next row of loops across the fabric, and these are produced, as already observed, with every third throw of the shuttle. Two wires only are used, and these are freed in turns by the same process which converts the loops into a pile. Each of them has a groove along its upper surface, and on this is run a sharp-edged knife, thus severing the loops and leaving two ends of each one projecting above the fabric. These are brushed up and dressed to produce the velvety nap. If some of the pile threads are left uncut, the velvet is then of the striped kind; and some is used altogether uncut. Fine velvets contain 40 to 50 rows of loops in an inch length of the fabric, and their production is therefore exceedingly slow and laborious. The process is moreover complicated by the use of two shuttles, a stouter thread being used after the wire than the two which succeed. Hence the production of a yard of plain velvet is considered a good day's work.—Various modifications have been introduced in the manufacture of velvet, among which is that of Mr. Gratrix, who produces the pile by the weft, the cut being then made in the direction of the warp. The pile threads are woven over a series of fine longitudinal knives, over the points of which the portions of the weft intended to form the pile slide successively as the cloth is woven; and the weft is severed in passing over the cutting portion of these knives, which are fixed. By some of the new methods the velvet is cut and embossed at the same time.—Lyons is the principal seat of the manufacture of broad velvets, such as those for cloak making called Ponson velvets, and St. Étienne is the principal seat of velvet ribbon manufacture. Trimming velvets of the finest kinds are made by hand in Rhenish Prussia.

VENAISSIN. See COMTAT-VENAISSIN.

VENANGO, a N. W. county of Pennsylvania, drained by the Alleghany river, French creek or Venango river, and Oil, Sugar, and Sandy creeks; area, 850 sq. m.; pop. in 1870, 47,925. A large part of the county is traversed by spurs of the Alleghany mountains. The soil along the streams is fertile. Iron ore and bituminous coal are very abundant, and there are traces of silver mines. Lumber and oil are exported largely. This county forms the centre of the great oil basin of Pennsylvania, and there are hundreds of oil wells in the valleys. (See PETROLEUM.) It is traversed by the Oil Creek and Alleghany River, the Alleghany Valley, the Pithole Valley, and the Franklin divisions of the Lake Shore and Michigan Southern, and of the Atlantic and Great Western railroads. The chief productions in 1870 were 72,158 bushels of wheat, 28,610 of rye, 216,753 of Indian corn, 335,899 of oats, 63,267 of buckwheat, 75,355 of potatoes, 268,405 lbs. of butter, 92,355 of wool, and 27,879 tons of hay. There were 5,113 horses, 6,963 milch cows, 7,412 other cattle, 32,764 sheep, and 10,379 swine; 6 manufactories of boots and shoes, 16 of carriages and wagons, 25 of machinery, 24 of refined petroleum, 10 flour mills, 9 saw mills, and 5 woollen mills. Capital, Franklin.

VENDACE, the name given in Great Britain to a fish of the salmon family and genus *coregonus* (Cuv.). This fish, *C. Willughbii* (Jard.), or *C. albula* (Cuv. and Val.), is 7 to 8 in. long, delicate greenish brown above, shading into silvery below, with the lower fins bluish white; iris silvery, tinged with yellow. The mouth is very small, and without teeth except a few minute ones on the tongue; scales large; first dorsal higher than long; lower jaw the longer. The arches of the gills are furnished on the inner side with numerous long processes barbed on each side and projecting into the cavity of the mouth; those of the two sides meet and form a complete strainer, arresting the small crustaceans on which they feed until enough have been collected to be swallowed, the water at the same time flowing freely over the gills. It is highly esteemed for food, having somewhat the flavor of the smelt; it is caught only in nets; it is in best condition about Aug. 1, when it is fat and well flavored; the food consists chiefly of minute crustaceans.

VENDÉE, La, a W. department of France, formed from the old province of Poitou, bordering on Loire-Inférieure, Maine-et-Loire, Deux-Sèvres, Charente-Inférieure, and the bay of Biscay; area, 2,588 sq. m.; pop. in 1872, 401,446. The surface is level or undulating, and marshy along the coast. The marshy district is known as *le Marais;* the woody tract in the centre of the department as *le Bocage;* and the rest of the country as *la Plaine*, a fertile district watered chiefly by the river Vendée. The navigable streams are the Autise, Vendée, Lay, Vic, Sèvre-Niortaise, and Sèvre-Nantaise. The coasts are low, and there are but two harbors, Sables-d'Olonne and St. Gilles. The chief productions are grain, wine, hemp, flax, wool, cattle, coal, and metals. The manufactures are unimportant. It is divided into the arrondissements of Napoléon-Vendée, Sables-d'Olonne, and Fontenay-le-Comte. Capital, Napoléon-Vendée.—La Vendée is famous for a royalist insurrection after the proclamation of the first republic, which spread over Lower Poitou, Anjou, Lower Maine, and Brittany. The movement was semi-religious, and originated with the peasantry in 1793, under the lead of Jacques Cathelineau. (See CATHELINEAU.) The count Henri du Verger la Rochejaquelein became especially distinguished as leader of the insurgents; but they were signally defeated in December, 1793, and hundreds of them massacred. In the following spring the war broke out again under La Rochejaquelein, Stofflet, and Charette. (See LA ROCHEJAQUELEIN, and CHARETTE.) The first was killed at Nouaillé, March 4, 1794, after a desperate struggle. The Chouans, with whom the Vendeans were afterward united, appeared at the same time N. of the Loire, in the departments of Morbihan and Côtes-du-Nord. (See CHOUANS.) The convention made a peace with the Vendeans early in 1795, guaranteeing to them a general amnesty, freedom of religious worship, exemption from military service, and indemnification for their losses. But the landing of a body of French *émigrés* at Quiberon in June encouraged them to take up arms again. Gen. Hoche was sent against them, and succeeded, after Stofflet and Charette and other chief leaders had been shot (February and March, 1796), in enforcing submission. The cruel punishments of 1793-'4 were not repeated. Far less important insurrectionary movements took place in 1799 and 1800, and during the hundred days (1815), when the marquis Louis du Verger la Rochejaquelein, brother of Henri, the commander of the last Vendean army, was killed, June 4. —See Crétineau-Joly, *Histoire de la Vendée militaire* (4 vols., Paris, 5th ed., 1865).

VENDÔME (anc. *Vindocinum*), a town of France, in the department of Loir-et-Cher, on the Loir, 18 m. N. W. of Blois; pop. in 1872, 9,938. It was formerly capital of the district of Vendômois, which comprised parts of the present departments of Loir-et-Cher and Sarthe. It contains the ruined château of the dukes of Vendôme, a lyceum, a public library, and manufactories of leather, gloves, and cotton goods. Several combats took place in the vicinity previous to and after the German occupation of the city (Dec. 16, 1870).

VENDÔME. I. César, duke de, a French prince, the eldest son of Henry IV. by his mistress Gabrielle d'Estrées, born in the castle of Coucy, Picardy, in June, 1594, died in Paris, Oct. 22, 1665. He was legitimated in his infancy, and in 1598 made duke of Vendôme and betrothed to the daughter of the duke de Mercœur, who resigned to him the government of Brittany. In 1610 he was allowed to take rank next to the princes of the blood. During the reign of his half brother Louis XIII., he participated in the conspiracy of Chalais against Richelieu (1626), was incarcerated for four years at Vincennes and Amboise, and banished for several years afterward. In 1641 he was charged with an attempt to poison Richelieu, and escaped to England. After the death of Richelieu he returned home, and was treated with great favor by the queen regent Anne of Austria; but he lost her good will by his active part in the Fronde. In 1650, having made his peace with the government, he was appointed governor of Burgundy. In 1653 he took Bordeaux from the Frondeurs, and in 1655, in the capacity of grand admiral of France, defeated the Spanish fleet off Barcelona. He left two sons, Louis and François, the latter of whom was the celebrated duke of Beaufort. (See BEAUFORT, FRANÇOIS DE VENDÔME, duke of.) **II. Louis,** duke de, son of the preceding, known as the duke de Mercœur during his father's life, born in 1612, died in Aix, Aug. 6, 1669. He served abroad, returned to France after Richelieu's death, and became in 1649 viceroy and commander of the French troops in Catalonia. He married in 1651 Laura Mancini, a niece of Cardinal Mazarin, was made commander in Provence, and placed in 1656 at the head of the French army in Lombardy. On his wife's death (1657) he became a priest, was made cardinal, and held the office of papal legate in France. **III. Louis Joseph,** duke de, a French general, son of the preceding, born in Paris, July 1, 1654, died at Tiñaroz, Catalonia, June 11, 1712. He was first known as the duke de Penthièvre, entered the army in 1672, distinguished himself in Alsace under Turenne and in Flanders under Créqui, and became governor of Provence in 1681. He distinguished himself at the battles of Steenkirk, Aug. 3, 1692, and Marsaglia, Oct. 4, 1693. In 1694 he became "general of the galleys," and in 1695 chief commander in Catalonia. In 1697 he besieged Barcelona, defeated the Spanish army which attempted to relieve the city, and forced it to surrender, Aug. 10; but in the same year it was restored to Spain in accordance with the treaty of Ryswick. On the breaking out of the war of the Spanish succession, he was, after the capture of Marshal Villeroi in Cremona, placed in command of the French army in Italy, and arrested the progress of Prince Eugene; but he was overtaken by his opponent at Luzzara, August, 1702, and saved himself from a disastrous defeat only by his generalship and intrepidity. After a fruitless attempt to reach Germany through Tyrol, he returned to Piedmont, where he took several strongholds, and defeated Prince Eugene at Cassano (1705), and Reventlow at Calcinato (1706). After the battle of Ramillies he was called to Flanders to command the French army under the grandson of Louis XIV., the duke of Burgundy; hampered in his movements by those who surrounded the young prince, he could not prevent the junction of Marlborough and Eugene, failed to effect a junction with Berwick, and was defeated at Oudenarde (1708). Disgusted with the treatment he received, and feeling that he had lost the confidence of the king and was hated by Mme. de Maintenon, he retired from active service. In 1710 Philip V. of Spain, deserted by Louis XIV., his grandfather, who was now scarcely able to defend himself, asked that Vendôme should be sent to his assistance. The old warrior went at once to Valladolid, gathered crowds of volunteers, inspired the adherents of Philip with new confidence, and brought him back to his capital; then he defeated and captured at Brihuega an English corps under Stanhope, and finally won at Villaviciosa, Dec. 10, 1710, a decisive victory over the Austrian general Stahremberg, which firmly established Philip on his throne. He was completing the conquest of Catalonia when he died suddenly.

VENEDEY, Jakob, a German author, born in Cologne, May 24, 1805, died near Badenweiler, Feb. 8, 1871. He studied at Bonn and Heidelberg, and was employed in his father's law office at Cologne till 1832, when his work on juries and his participation in the Hambach festival caused him to be imprisoned; but he escaped to France, and in 1835 established in Paris a monthly periodical, which resulted in his expulsion, and having returned he was again expelled in 1837. He retired to Havre, and was only permitted to reside in the capital after the appearance in 1840 of one of his works which was favorably received by the French academy, and caused Arago and Mignet to interfere in his behalf. In 1848 he returned to Germany, and became a member of the Frankfort parliament and of the rump parliament at Stuttgart. Subsequently he was expelled from Berlin and Breslau, and resided chiefly at Bonn till 1853, when he became a lecturer at the university of Zürich. In 1855 he returned to Germany. He first published in French, then in German, *Römerthum, Christenthum, Germanenthum* (Frankfort, 1840). His other works include *Irland* (Leipsic, 1844); *England* (1845); *Das südliche Frankreich* (Frankfort, 1846); *Geschichte des deutschen Volks* (4 vols., Berlin, 1854–'62); and biographies of Hampden (1843), Washington (1862), Franklin (1863), and Stein (1868).

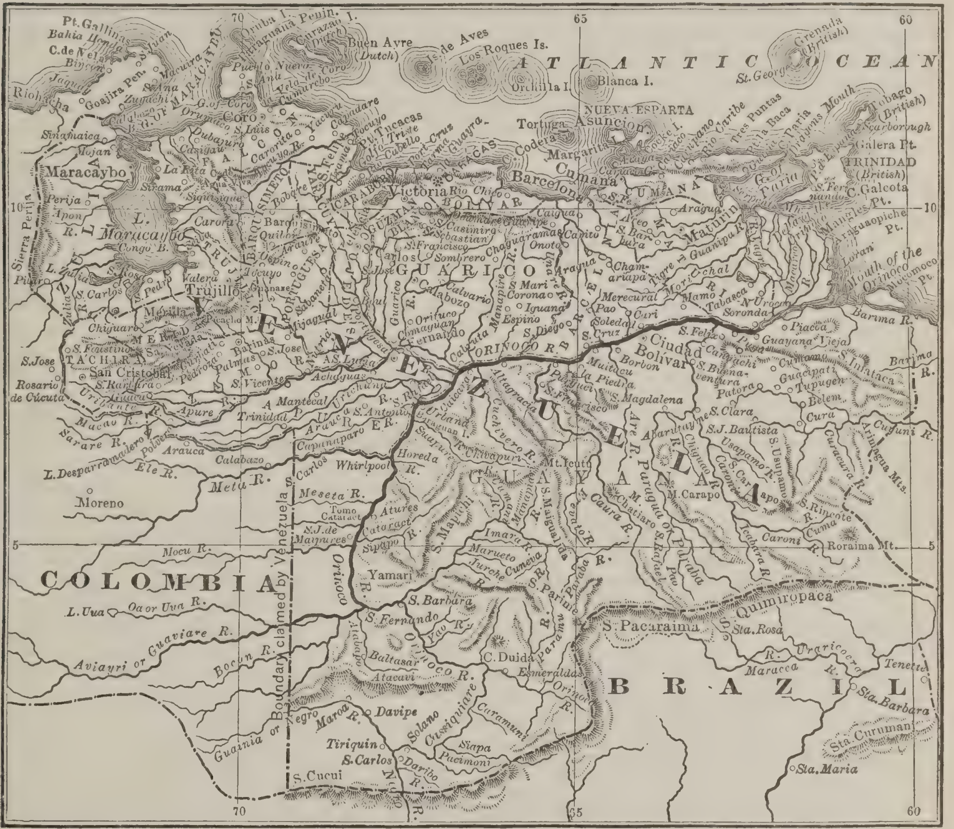
VENEER, a thin sheet of wood or other material used to give an exterior finish to articles of cabinet or other work, the body of which is of cheaper material. The art of veneering is not modern; according to Pliny it was introduced about his time. Veneers were formerly cut with thin hand and pit saws, from blocks of wood. In 1806 Mr. Brunel patented a method of splitting them from straight-grained wood, but curved and knotted wood required to be sawed. Circular saws replaced the old straight saws. Veneer is now sawed by very thin reciprocating gang saws, which work with so much precision as to saw very wide strips as thin as cardboard. The work is done in establishments usually connected with saw mills. The cabinetmaker in applying the veneer roughens one surface, that the glue may hold it firmly to the body of the work. The outer surface of the veneer is afterward dressed with planes and scrapers, and polished with sandpaper and brushes or pumice.—Veneers of ivory and of bone are used for some purposes; and in Paris a pianoforte has been entirely covered with a single sheet of ivory cut in a spiral from an elephant's tusk. The manufacturer advertised to supply such sheets 150 in. long and 30 in. wide. In the United States department of the great exhibition of 1851 there was a veneer of this kind 40 ft. long and 12 in. wide.—The inlaying of thin strips of wood or veneers in wood of other colors has been treated in the article BUHL WORK.—A remarkable variety of veneering has been introduced into the United States, called "pressed work." Any number of veneers are laid together, the grain of each one at right angles to that of the adjacent layers, and all after being well saturated with glue are strongly compressed until the whole is united in one mass. For curved work the pressure is applied upon the mass placed while hot in moulds. By this method the backs of chairs are made in graceful curves and of great strength, the crossing of the grain preventing all danger of splitting. Strong plain wood, as black walnut, may be used for the inner layers, while the outer may be of rosewood or other highly ornamental wood. The tops of tables thus made are not liable to warp, and the method has been successfully applied to the construction of tables for sewing machines. Dished or spheroidal pressed work may be made in any desired curves by cutting the veneers into strips of varying width according to the part of the mould into which they are to be pressed.—Ornamental surface in relief has been given to veneers by pressing them between two moulds or dies, and filling the concavities on the hollow side with mastic or some plastic substance. Before pressing them, the surface to be in relief is smoothed and polished, and paper is pasted over the other. The dampness of the paste favors the adjustment of the wood to the irregularities of the die, from which the veneer is not removed until all moisture has disappeared.

VENETIA, in ancient geography, a district of upper Italy, bounded by the Carnic Alps, the Timavus (now Timavo), the Adriatic, and the Athesis (Adige), which separated it from Cisalpine Gaul proper, of which it sometimes formed part. It was a fertile territory, the principal productions of which were wool, sweet wines, and race horses. The chief cities were Aquileia, Ateste (Este), Patavium (Padua), Vicentia (Vicenza), and Tarvisium (Treviso). The inhabitants, the Veneti or Heneti, were reputed to be descendants of the Paphlagonian Heneti, brought to the shores of the Adriatic by Antenor, a Trojan hero, the legendary founder of Patavium (Padua). Others supposed them to be kindred to the Celtic Veneti in Gallia Lugdunensis; but they not only spoke a different language from that of the Celts, but also lived in continual hostility to the Gallic tribes in their neighborhood. According to Herodotus, the Veneti inhabited Illyria. Modern critics are inclined to regard them as Slavs, of the same branch as the Winds in the neighboring Illyrian provinces of Austria. They early entered into an alliance with Rome, and subsequently became her subjects without resistance. Under the earlier emperors they enjoyed great prosperity, but during the 3d, 4th, and 5th centuries their territory was frequently devastated by the invading barbarians. The invasion of the Huns, under Attila, drove many of them to the islands and lagoons of the Adriatic, where they became the founders of Venice, with whose history that of Venetia became closely connected. The republic gradually absorbed the petty states which had arisen in the early part of the middle ages, and extended its possessions in Italy beyond the limits of the ancient territory. (See VENICE.) In 1815 the country as far W. as the Mincio and S. to the Po was made part of the Lombardo-Venetian kingdom of the Austrian empire, and in 1866 became a territorial division of the kingdom of Italy; it is bounded N. W., N., and N. E. by Tyrol and Carinthia, E. by Görz and Gradisca, S. E. by the gulf of Venice and the Adriatic, S. by the division of Emilia, and S. W. and W. by Lombardy; area, 9,060 sq. m.; pop. in 1872, 2,642,807. It is divided into the provinces of Belluno, Padua, Rovigo, Treviso, Udine, Venice, Verona, and Vicenza. The chief rivers are the Po, Adige, Brenta, and Piave. Lake Garda and the Mincio form part of the western boundary.

VENEZUELA, United States of, a republic of South America, extending from lat. 1° 8′ to 12° 16′ N., and from lon. 60° to 73° 17′ W. It is bounded N. by the Caribbean sea, E. by the Atlantic and by British Guiana, S. by Brazil, from which it is partly separated by the Pacaraima mountains, and W. by the United States of Colombia. Its maximum length from E. to W. is about 900 m., and its maximum breadth from N. to S. 770 m. The area (including the islands), according to the *Almanach de Gotha*, is 403,000 sq. m. Codazzi, in his *Resúmen de la geografía de Venezuela* (1841), set it down at 431,000 sq. m. It is divided into 20 states, 1 federal district, and 1 territory, which, with their population and capitals, are as follows:

STATES, &c.	Pop. in 1873.	CAPITALS.
Apure	18,635	San Fernando.
Barcelona	101,396	Barcelona.
Barquisimeto	143,818	Barquisimeto.
Bolivar	129,143	La Guayra.
Carabobo	117,605	Valencia.
Cojedes	85,678	San Carlos.
Cumaná	55.476	Cumaná.
Falcon or Coro	99.920	Coro.
Guárico	191,000	Calabozo.
Guayana	34,058	Ciudad Bolivar.
Guzman Blanco	94,151	Victoria.
Maturin	47,863	Maturin.
Mérida	67,849	Mérida.
Nueva Esparta (Margarita)	80,983	Asuncion.
Portuguesa	79,934	Guanare.
Táchira	68,619	San Cristóbal.
Trujillo	108,672	Trujillo.
Yaracui	71,689	San Felipe.
Zamora	59,449	Barinas.
Zulia	59,235	Maracaybo.
Distrito Federal	60,010	Carácas.
Territory of Amazonas	23,048	....
Total	1,784,194	

Differences between populations of certain states in the above table and the figures given in the separate articles on such states, different capitals, &c., are attributable to the new territorial division of the republic and the official census of November, 1873, first published in 1875. The populations of some of the chief cities, according to that census, were as follows: Carácas, the capital, 48,897; Valencia, 28,594; Barquisimeto, 25,664; Maracaybo, 21,954; Maturin, 12,944. The white population was estimated at about 1 per cent. of the total, and the foreigners resident in the republic at 10,000. Much the largest part of the population consists of half-breeds and hybrids from the union of Europeans (chiefly the early Spanish colonists) and Indians, and the intermingling of these and negroes. Of pure-blooded Indians Codazzi in 1841 enumerated 49 wild and independent tribes, numbering in all 52,415, of whom 9,000 were Goajiros occupying the eastern half of the Goajira peninsula claimed by Venezuela.—The coast line, from Cape Chichibacoa in the N. E. extremity of the peninsula of Goajira to the boundary line with British Guiana, nearly 2,000 m., following the sinuosities, about one tenth of which is washed by the Atlantic, is notched by numerous gulfs, bays, and inlets. The first deep indentation, beginning at the east, comprises the main mouth of the Orinoco, between Points Mocomoco and Araguapiche, 65 m. apart. About 90 m. W. of the latter point, at the N. W. extremity of the great swampy delta of the Orinoco, is the gulf of Paria, the shores of which are mostly bold and rocky, 100 m. long and 47 m. wide, separated from the Caribbean sea by the peninsula of Paria, and from the Atlantic by the island of Trinidad. The gulf of Cariaco is a narrow inlet, nearly 50 m. long, between the peninsula of Araya and the Cumaná coast, presenting a picturesque and commodious roadstead. From Cumaná westward to Barcelona the coast, though still rocky, becomes gradually lower and more even; and from the latter port to Cape Codera it is low and sandy, and interspersed with extensive salt marshes. Between Cape Codera and the gulf of Triste (formed by a rectangular northward bend of the coast, 25 m. W. of the port of Puerto Cabello) is comprised the most rugged portion of the seaboard, flanked by the Venezuelan coast range of mountains, and notched by a series of inlets fringed with luxuriant vegetation. This strip of coast is 150 m. long. Beyond Point Tucacas, at the N. W. extremity of the gulf of Triste, the shore is again low and sandy, with intervals of mangrove marshes, and occasional low spurs from a branch of the far distant Mérida mountains. From the middle of the Goajira coast to Cape Chichibacoa it presents an uninterrupted perpendicular wall of rock. Enclosed between the Goajira peninsula on the west, the rocky peninsula of Paraguaná on the east, and the main coast on the south, lies the gulf of Maracaybo, or more properly of Venezuela, the largest of the republic, having an area of about 6,500 sq. m. The eastern branch of this gulf, called by native geographers the *golfete de Coro*, has an area of about 1,000 sq. m., and, being completely sheltered from the



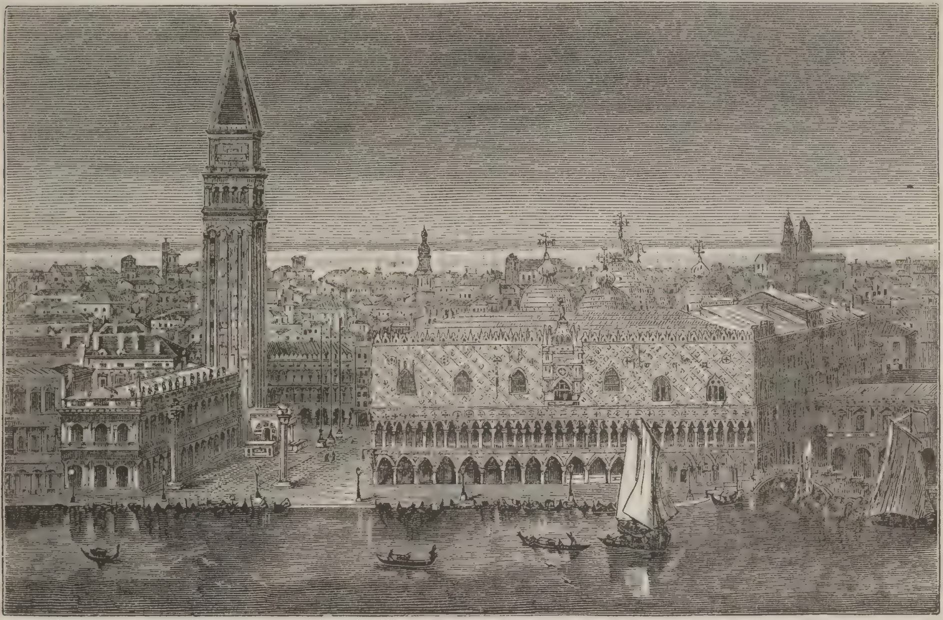
prevailing winds by the Paraguaná peninsula, forms a vast and commodious haven. Of the 32 ports, those of La Guayra and Puerto Cabello are most frequented by foreign shipping. The fortifications of La Guayra have been lately restored, and are to be supplied with a complete armament. Cumaná, at the mouth of the gulf of Cariaco, is well sheltered and defended, as is also the less important port of Barcelona, on the banks and near the mouth of the Neveri. The harbor of Coro, though much exposed, is the seat of an active trade with the West Indies; but this port and that of Maracaybo on the gulf of that name were in 1875 closed to foreign traffic, and vessels to and from them are now entered and cleared at Puerto Cabello. Ciudad Bolivar (formerly Angostura), on the Orinoco, 240 m. from the sea, is the entrepot for the products of all the regions drained by that river and its more important affluents, two of which, the Meta and Apure, are navigated by steam. No fewer than 71 islands fringe the coast, the largest being that of Margarita, which constitutes a state, and all being of volcanic origin except those in the various river mouths and in the outlet of Lake Maracaybo, which are accumulations of mud or sand. The larger islands after Margarita are Chimana, Caraca, and Borracha off the Barcelona coast; Tortuga, further seaward; Orchila or Orchilla, affording large quantities of the dye of that name; the Roques and Aves, west of Orchilla; and Blanca, due N. from Margarita. Nearly all these islands are inhabited by large numbers of goats.—About 107,000 sq. m. of the republic are occupied by mountains, forming two separate systems. The first is a ramification of the Colombian Andes, which bifurcate in the node or knot of Pamplona, lat. 7° 15′ N., lon. 73° W. One branch runs N. to lat. 10° 50′, then curves N. E. and terminates in Cape Chichibacoa at the N. E. extremity of the Goajira peninsula. From Pamplona to the Venezuelan frontier, lat. 9° N., it is called the Sierra de Ocaña; thence to Goajira, Sierra de Perija, a range which nowhere attains a height of 5,000 ft.; and in the peninsula it receives the name of Oca mountains. The last two ranges form the N. W. boundary line with Colombia. The other and principal branch, comprising the great alpine region proper of the republic, trends N. E. to the snowy mountains of Mérida, which, gradually declining toward the Páramo de las Rosas in the hilly districts of Tocuyo and Quibor, sink on the right bank of the Rio Cojedes S. of Barquisimeto. On the opposite bank of that stream the chain again rises abruptly toward Puerto Cabello, whence, under the name of Venezuela Coast chain, it extends like a wall uninterruptedly E. to the promontory of Paria, with a mean elevation of but 4,800 ft.; the two loftiest summits, the Silla de Carácas and the Picacho de Naiguatá, reaching respectively 8,547 ft. and 9,100 ft. This marginal chain is divided into many ranges enclosing numerous fine valleys, as that of Aragua, which yields the indigo and other tropical plants and European wheat in great abundance. The Mérida mountains, with a mean altitude of 6,000 ft., comprise 31 summits exceeding 10,000 ft., the loftiest of which are the two peaks of the Sierra Nevada, 15,066 (the culminating point of Venezuela) and 15,000 ft. The second system is that of the Parima or Parime mountains, extending over the whole southern division of the Orinoco basin, still but little known. To this system belongs the Sierra de Pacaraima, forming a part of the southern boundary of the republic. The other principal ranges, mostly extending N. W. between the Pacaraima chain and the Orinoco, are those of Parima (highest summit, 7,608 ft.), Maraguaca (8,151 ft.), Maigualida, Chuchivero, Guachimacari, Cuneva, Guayapú, Sipapo, Cerbatana, Rinocote, Carapo, Imataca, and Upata. Chief among the isolated peaks is the Duida mountain, between the Sierra de Parima and the upper Orinoco, with an elevation of 8,823 ft. (See DUIDA.)—Upward of 1,000 rivers drain the territory of Venezuela, all but 12 of which have their entire course within its limits. The Orinoco, ranking third among the rivers of South America, has a course of 1,500 m., pours into the ocean by 17 mouths the waters of over 400 navigable tributary streams, and drains a region of 250,000 sq. m. (See ORINOCO.) The Rio Negro, rising in Colombia, flows through the S. W. corner of Venezuela, receiving an extensive tribute from the Orinoco by the Cassiquiare, whereby navigable communication is established between the Orinoco and Amazon. Into the Caribbean sea and the gulfs of Venezuela and Paria flow 230 rivers, the largest of which are the Tuy, Tocuyo, and Unare, and 400 minor streams; and into the lake of Maracaybo about 500, of which only 100 are perennial. Venezuela contains over 200 lakes and lagoons. The most interesting lake is that of Valencia, the Tacarigua of the Indians, bounding the southern margin of the delightful valley of Aragua, and 1,599 ft. above the sea. From excessive evaporation its islands, now 22 in number, continually increase in size, and since the beginning of the present century several sand banks have become true islands, called *aparecidas* (newly appeared). The lake contains several species of fish peculiar to itself. The principal lagoons are those of Maracaybo (called also lake) in the state of Zulia, nearly 100 m. long, with a maximum breadth of 75 m.; Unare, separated from the sea by a sandy tongue of land, where excellent salt is produced; Taiguaiguai, Palmananita, Encantada, Gacasonica, with an outlet to the sea and navigable by schooners, and Lagunillas in Mérida, famous for its *urao* (sesquicarbonate of soda, or the *trona* of commerce). Most of the smaller lagoons become altogether dry in summer.—The geology of Venezuela has been but little studied, save in the portions visited by Humboldt and Schomburgk. The northern branch of the Andes, and the eastern to the banks of the Cojedes, are granitic, while the rocks of the littoral chain are metamorphic; but the surface rocks of Falcon and Zulia belong for the most part to the carboniferous era. Calcareous rock underlies the argillaceous surface stratum of the plains (*llanos*), which, stretching from the southern edge of the plateau of Carácas to Brazil, and from the head waters of the Vichada to British Guiana, were once probably the bed of a vast inland sea. Diamonds have been found in Nueva Esparta, and amethysts in Bolivar. Gold occurs in Bolivar, and especially in Guayana, where some mines are still worked, and in the sands of many of the rivers discharging into the Caribbean sea; platinum in Bolivar; silver in Yaracui, Barquisimeto, Barcelona, Mérida, Trujillo, and Bolivar; copper in large quantities in the littoral chain, and particularly in Bolivar, though the once productive mines have been abandoned; and tin, zinc, lead, quicksilver, and antimony in various parts of the country. Iron is reputed abundant in Bolivar, Falcon, Nueva Esparta, and Barcelona; but owing to lack of skill in the art of mining and the prevalence of civil wars, no mines have been worked. Alum, sulphate of magnesia, gypsum, and saltpetre abound; there are several varieties of marble; salt is extensively produced in various parts of the coast; phosphate of lime is extracted from the largest island of the Roque archipelago; and sulphur might easily be made available in extensive quantities in Barcelona, Falcon, and Mérida. Asphaltum and petroleum are said to be plentiful in the littoral states from Cumaná to Zulia, and coal beds occur in Falcon. From the lagoon of Lagunilla in Mérida are extracted considerable quantities of *urao*. Among the numerous thermal springs are those of Las Trincheras near Valencia, of Onoto, and of Mariara, the temperatures of which are 210°, 112°, and 149° F. respectively; but the most remarkable are those of the Quiva, in the vicinity of Coro, where two large white semispheroids contain in some 40 cavities many-colored waters at temperatures varying from 40° to 152° F.—Venezuela, in common with all the mountainous countries of Spanish America, presents three grand divisions as to climate: the *tierras cálidas* (hot lands), *tierras templadas* (temperate lands), and the *tierras frias* (cold lands). In the first region, extending to 2,000 ft. above the sea, the mean annual temperature for the whole republic is 80° F.; but in many portions a much higher temperature prevails, as in La Guayra, where it ranges from 100° to 110° F.; in Barcelona, whose capital Humboldt notes as one of the hottest and most insalubrious places on the globe; and in Maracaybo, by far the hottest locality in the country. In the temperate region, mostly confined to the *mesas* or plateaus from 2,000 to 7,000 ft. above the sea, in the mountains designated as the second branch of the first system, and in the coast chain, the thermometer fluctuates between 65° and 75°. The climate of this region, the most populous of Venezuela, is one of perpetual spring and remarkably salubrious. To the third or cold region belongs all above 7,000 ft., including the bleak, chilly, and inhospitable *páramos* or highest table lands. A remarkable fact, hitherto unaccounted for, is the uninhabitableness of the Venezuelan table lands above 8,000 ft., notwithstanding their proximity to the equator, while those of Mexico (some over 8,000 ft.), Quito, Bogotá, Cuzco, and Oruro (the last over 13,000 ft.) are among the most delightful regions of the earth. There are here, as elsewhere in tropical America, but two seasons, the dry and the rainy. The former, called summer, usually lasts from November to April; winter extends over the remaining months, save in Guayana, where, owing to the dense forests, the rains are more persistent than in the other states. The mean annual rainfall at Carácas is about 330 inches in 80 days. Yellow and intermittent fevers are common throughout almost the whole of the coast region during winter, and elephantiasis and goitre are the great scourges of the plateaus. The prevailing winds on the coast during summer, and especially in December and January, are those from the north and northeast. Earthquakes are frequent, and often very disastrous, as that of February, 1610, which destroyed several towns in Táchira and Mérida; that of October, 1766, which laid Cumaná in ruins; and that of March 26, 1812, the most terrible of all, which completely ruined the city of Carácas, then numbering 50,000 inhabitants.—The soil, except in the sandy regions of the coast and the lofty and arid *páramos*, is for the most part exceedingly fertile. The region below the level of 3,000 ft. is the country of the palms, here inferior only in variety to those of the Brazilian forests. Most noteworthy among them are the sago palm, which thrives in the low lands; the *chiquichique* and the *yagua*, whose fibrous tufts are converted into cordage, while the yagua yields also an excellent oil; the *chaguarama*, furnishing material for thatch and laths; and the giant royal palm, the wax palm, and several other species. The cocoa palm is, after the common fan palm, the most abundant, and cocoanut oil is exported in considerable quantities. Mention should likewise be made of the breadfruit tree and peach palm, esteemed for their farinaceous fruits. The woods of the central valleys and the immense forests of Guayana offer a great variety of timber and cabinet woods, including mahogany, rosewood, satinwood, black and white ebony, &c. The *bejuco mavacure*, from the juice of which the Indians prepare their famous arrow poison *curare* or woorara, is common in Guayana. The true cinchona forms whole forests at elevations varying from 2,700 to 4,500 ft. above the sea. The *caucho* or India-rubber tree is abundant, as are also Brazil and other dye woods and plants, including the celebrated dividivi, gums, resins, spices, and medicinal plants and herbs. The principal cultivated products and the number of acres devoted to each in 1873 are as follows:

PRODUCTS.	Acres.	PRODUCTS.	Acres.
Cacao	51,490	Wheat	9,282½
Coffee	304,725	Cocoa	1,837½
Tobacco	9,752½	Plantains	68,510
Cotton	15,000	Various grains and pulse	65,475
Indigo	1,487½	Fruits	21,000
Sugar cane	87,000		
Yuca	25,000		
Maize	37,957½	Total	698,217½

From these figures it appears that only about $\frac{1}{368}$ of the area of the republic, or 1,094 sq. m., is cultivated, while the whole cultivable region is said to embrace an area of 105,084 sq. m. The coffee shrub was introduced into Venezuela in 1784, and it thrives well at elevations between 650 and 5,500 ft. The chief cacao plantations are along the coast from Guiria (Cumaná) to the mouth of the Tocuyo. Indigo culture, once very extensive, has been gradually giving place to that of other staples for 30 years; the product in 1841 was 552,781 lbs., and in 1873 only 182,956 lbs. But little sugar is now exported, though it is largely produced; of 90,690,817 lbs. manufactured in 1873, only 4,997,465 lbs. was shipped to foreign ports. Cotton is sown in May and June, and flowers in November. The plantain is a staple article of food for a large portion of the inhabitants; as is also maize, which is largely cultivated in the lowlands. Tobacco is extensively grown for export, that of Barinas being especially esteemed in Europe.—Wild animals are very numerous. The principal quadrupeds are the jaguar, panther, tiger cat, tapir, a species of black bear, fox, peccary, deer, badger, and ferret. Venezuela has 14 varieties of monkeys, one of them, the *titi*, being in some districts not over 6 in. in length. The rodents include squirrels, rats and mice, porcupines, rabbits, and agoutis. Among the amphibious quadrupeds are the otter, capybara, and *chigüire.* Sloths, armadillos, and two species of anteaters are the principal edentates. The cetaceans are represented by the manatee, *touinas* (a kind of large dolphin), cachalot, and sword fish, the two first abounding in the large rivers. The principal reptiles are the cayman and the *baba*, a smaller species of the same genus; the iguana, basilisk, and chameleon; the boa, attaining at times a length of 50 ft.; the *traga venados* (deer swallower); and 15 varieties of snakes, 10 of which, especially the rattlesnake and *macaurel*, are venomous. Myriads of noxious insects infest all parts of the lowland; and gigantic spiders and centipedes more than 12 in. long, whose sting, in common with that of the yellow scorpion (likewise very numerous here), produces terrible fevers. Enormous bats commit great ravages among the cattle, sucking their blood, and attacking even man himself during his sleep. Excellent fish abound in the lakes and rivers and along the coasts, especially the *liza*, found in the channel separating the island of Margarita from the mainland, and salted and dried for export and for the interior. Margarita was formerly celebrated for its pearl fishery, which is still continued, but much reduced in value. There are two kinds of vultures, three of hawks, and two of owls; partridges and pigeons are plentiful; there are 14 different species of waders and 10 of divers; the Venezuelan parrots yield only in variety to those of Brazil; and the exquisite plumage of the small birds, conspicuous among which are trogons, tanagers, and toucans, is unsurpassed in the world. All the European barnyard fowls thrive well in the temperate region. Vast herds of horned cattle, sheep, horses, mules, asses, and swine roam in a wild state over the plains, whence they take refuge in the elevated districts during the rainy season. The number and value of the live stock in the whole republic in 1873 were returned as follows: horned cattle, 1,389,802, value $22,236,832; sheep and goats, 1,128,273, value $1,692,409; horses, 93,800, value $4,690,000; mules, 47,200, value $1,888,000; asses, 281,000, value $1,686,000; and swine, 362,597, value $2,175,042; total value, $34,368,282.—The Venezuelans in general are intelligent and courteous. Though all enjoy equal civil rights, without respect of caste or color, the whites retain the power of the state in their own hands; while the mixed races, though more indolent and apathetic, are given to turbulence, and are commonly the instigators of factious quarrels and revolutions. The chief industries are agriculture and cattle rearing. Continued internecine strife until lately, and lack of adequate implements and of suitable means of transport to the coast, have materially retarded development; but much has been done since 1873 by Gen. Guzman Blanco's government toward building roads and extending the navigation by steam of the great rivers, lagoons, and lakes of the country. The manufactures include cotton fabrics both by hand and machinery, hammocks, hats, cordage, &c.; in Mérida, woollen carpets, tastefully variegated with brilliant colored flowers from a native dye, are extensively made; ship building is carried on in Puerto Cabello; numerous brick yards are found in different parts of the republic; and several thousand persons are employed in manufacturing cigars and cigarettes, exquisite preserves and sweetmeats, and cacao. Several kinds of oil are made, especially cocoanut, sesame, and *tártago* oils; and perfumes and essences from magnificent and fragrant flowers are extracted in large quantities. There are also a few cart and carriage factories. The foreign commerce is now likely to increase rapidly with the preparation of new and much needed roads, and the extension of steam traffic on the lakes and rivers, and above all with the inauguration of an era of peace. Among exports coffee still holds the first rank, that of Maracaybo and La Guayra being in good demand in the European and American markets. The other principal articles of export are cotton, cacao, sugar, indigo, tobacco, salt, hides, cattle, tallow, horns, sarsaparilla, and dye and cabinet woods. The imports include cotton, linen, and silk goods, flour, provisions, hardware, wines, and specie. The total value of the exports in the year 1872–'3 was $21,320,495, and of the imports $11,264,976. The articles exported and the quantities in 1872–'3 were as follows: coffee, 23,998,585 lbs.; cotton, 5,648,323 lbs.; indigo, 182,976 lbs.; sugar, 5,017,469 lbs.; cacao, 7,573,586 lbs.; tobacco, 1,100,297 lbs.; hides, 130,000; skins (deer and goat), 150,000; cattle, 6,831 head. The total value of the exports to the United States (port of New York) in the years ending June 30, 1870 and 1875, respectively, was $1,897,800 and $4,206,264; of the imports from New York in the same years, $1,122,195 and $1,980,775. The exports to the United States have thus increased by more than 100 per cent. in five years. The articles shipped to that destination are usually coffee, cacao, cotton, indigo, hides, skins, woods, and drugs. The shipping movements for the port of La Guayra in 1872–'3 were: entered, 177 vessels, tonnage 93,424; cleared, 128 vessels, tonnage 131,110. For the port of Puerto Cabello in 1874 they were: entered, 212 vessels, tonnage 105,046; cleared, 126 vessels, tonnage 78,227. The number of vessels entered at all the ports of the republic in 1874 was 2,200. In the year ending June 30, 1875, Venezuelan ports were visited by 17 steamers and 41 sailing vessels from New York, of 21,546 tons. The principal Caribbean ports are now visited monthly by the steamers of one American and seven European lines. The coasting trade, which is considerable, is carried on by national craft only, as are also the fisheries. The traffic between Carácas and its port La Guayra is conducted by means of road locomotives of recent introduction. Telegraphs have been established between Carácas and La Guayra, Coro, and other coast towns; and in February, 1876, materials were shipped from New York for several other lines.—By the terms of the constitution of March 28, 1864, Venezuela became a federal republic closely modelled after that of the United States. The executive power is vested in a president elected for four years, aided by the six ministers of interior and justice, foreign affairs, finance, public works, war and the navy, and public credit. The president has no veto power. The legislative power resides in a congress composed of a senate and a house of representatives, whose members are deputed from the corresponding houses in the individual states. The central judicial power is confided to the supreme court, three superior courts, and the courts of first instance, of which there is one for each canton. The municipal government is conducted by the council of each canton. The constitution in its other provisions resembles that of the United States of America; but its modifications and amendments have of late been too frequent and too numerous for mention here. The army was said, in the president's message of February, 1875, to be 30,000 strong; but a subsequent official publication gave it at 10,000 infantry and artillery, and 78,000 militia. The national revenue amounted in 1873–'4 to $5,570,401, of which $4,565,857 proceeded from the customs and from public storage and tonnage dues; and the expenditures amounted to $5,209,351, although three fifths of the income was to have been appropriated to defraying the expenses of the government, and the remainder to be applied on the amortization of the national debts. On June 30, 1873, the home debt amounted to $16,439,383, and the foreign debt to $46,575,337. The government has recently resumed payment of the interest on these debts, after a suspension of several years.—Education, which has ever been more advanced in Venezuela than in the sister republics, though only in the higher branches, has become the object of most zealous care on the part of Guzman Blanco's administration, under whose auspices primary instruction, gratuitous and compulsory, has been decreed, and primary schools have begun to multiply rapidly. The university of Carácas had in 1874 19 professors and 165 students; and there are besides in that city a medical faculty and a school of arts founded by Guzman Blanco in May, 1870. Elsewhere in the republic there are national and private colleges, and a seminary (called university since the abolition of the seminaries by decree of September, 1872). A semi-official report published in 1875 set down the number of primary schools for the whole republic at 541, of which 141 were federal and the remainder municipal and private schools; the attendance at the former was 7,064, and at the latter 11,017. The religion of the people is the Roman Catholic, but all others are tolerated. The clergy are strictly subordinate to the civil power; the government exercises the patronage of the church, and the papal sanction, when required, is transmitted through it. The archiepiscopal see is at Carácas, and there are two bishoprics, one at Mérida and the other at Ciudad Bolivar.—The island of Margarita and the E. part of the coast of Venezuela were discovered by Columbus in 1498, and the whole coast by Ojeda and Vespucci in 1499. On entering Lake Maracaybo, they found an Indian village constructed on piles over the water (a common occurrence in those portions of the country liable to inundation), and thence called it Venezuela (Little Venice). This name, originally applied only to the region near the lake, was eventually extended to the whole country. The Spanish conquerors at first gave it the name of Costa Firme, and included under this name New Granada and Ecuador also; at the present day only the E. coast of Venezuela is known as Costa Firme. The first settlement was made about 1520, at Cumaná, which is consequently one of the oldest cities in the new world. Coro was founded in 1527. About 1540 indications of gold were discovered at several points along the coast range, and in 1545 Tocuyo was founded, Barquisimeto in 1552, Valencia in 1555, and Carácas in 1567. The demand for cacao, which was largely produced in the Dutch settlement at Curaçoa, led to the formation in 1700 of the Guipúzcoa company in Spain, which sent out emigrants to cultivate cacao and indigo. This company was dissolved in 1778. When Napoleon in 1808 made his brother Joseph king of Spain, Venezuela was among the first of the Spanish colonies to declare for the ancient dynasty; but as early as April 19, 1810, a revolutionary rising took place in Carácas, and on July 5, 1811, Venezuela proclaimed its independence. In 1812, by the treaty of Victoria, it returned to the sway of Spain; but in 1813 it again revolted under Gen. Bolivar, and, after a protracted conflict with varying success, the republic of Colombia, embracing New Granada, Venezuela, and Ecuador, was declared independent in 1819. (See Bolivar y Ponte.) The contest with Spain did not entirely cease till 1823, though the Spanish force had been for some time confined to a small territory. In 1821 a congress was called, and a constitution adopted for the new republic. In 1829–'30 the three states separated amicably, and a new constitution was adopted by Venezuela. For 15 years the presidency was held successively by Gen. Paez (see Paez, José Antonio), Dr. Vargas, and Gen. Soublette. From the accession of Gen. José Tadeo Monagas to the executive power, in March, 1846, until that of Gen. Falcon, in June, 1863, the country was never free from civil war. Falcon, after several years of tranquil possession of power, was deposed by a revolution in which Antonio Guzman Blanco took an active part, and which only terminated on the seizure of the reins of government by the latter on April 26, 1869, after a protracted war with varied success. Guzman Blanco now proclaimed a provisional government and himself the head thereof, with the title of "general-in-chief of the constitutional army of the confederation." He next exacted, from a congress convoked by himself at Valencia, in July, 1870, extraordinary powers, and the title of "provisional president of the republic." He was ultimately elected on Feb. 20, 1873, for four years. Guzman Blanco's administration, though republican in form, is dictatorial in fact, the president exercising supreme authority. Yet no abuses have been complained of, and the country is in a more prosperous condition than it ever had enjoyed since the colonial times. In the course of 1874 and 1875 a sum of $4,260,858 62 was disbursed for municipal improvements and highways. The claims of the United States, upward of $450,000, for materials furnished at the time of the war for Colombian independence, and indemnities for damage sustained by American citizens, are in course of liquidation (1876).

VENI. See Beni.

VENICE (It. *Venezia*). **I.** A province of Italy, in Venetia, bordering on the Adriatic and the provinces of Udine, Treviso, Padua, and Rovigo; area, 850 sq. m.; pop. in 1872, 337,538. The lagoons occupy half of the territory, but the tongue of land extending over 20 m. between them and the sea, and some of the islands, have fertile spots, where agriculture is improving. The principal rivers are the Adige, Brenta, and Piave. It is divided into the districts of Chioggia, Dolo, Mestre, Mirano, Portogruaro, San Dona, and Venice. **II.** A city, capital of the province, on the gulf of Venice, as the N. W. part of the Adriatic is called, in lat. 45° 26′ N. and lon. 12° 20′ E., 155 m. E. of Milan, and 250 m. N. by W. of Rome; pop. in 1872, 128,094. It stands in the midst of lagoons, collectively known as the lagoon of Venice, originally formed by the retreating of the sea. At Venice they are separated from the sea by a tongue of land (*lido*), extending at a distance of about 4 m. from the coast, and divided by gaps or cuttings, some of which form harbors (*porti*), and enclose numerous small islands into which piles were driven for the construction of the city. There are more than 100 canals, provided with small quays, and communication is further kept up by small streets, lanes, alleys, and courts, which with few exceptions are ill paved and overcrowded, and by about 400 bridges, generally steep but with easy steps. A viaduct 2 m. long, with over 200 arches, connects Venice with the principal railways at the Mestre junction. The two broadest canals, Della Giudecca and San Marco, divide the city proper from the island and suburb of Giudecca and from the island of San Giorgio. The so-called great canal (*canalazzo*) divides the city proper into two parts, and is spanned by two iron bridges erected in 1854 and 1858, and by the Rialto bridge, built of marble by Antonio da Ponte in 1588–'91, and called after the largest island (isola del Rialto, from *il rivo alto*, the deep stream). The canals are protected by batteries on both sides, and connected with Malamocco, Chioggia, and other harbors, and with the mainland, the former harbor (porto di Malamocco) being the deepest of all, and enabling large ships to come up to the city. The great canal is lined with magnificent buildings at the water's edge, from which there is immediate access to gondolas, of which there are more than 4,000, all painted black, in accordance with an old regulation. The circumference of the city is about 8 m. It seems from every direction to be floating on water, and presents a unique appearance of fairy-like picturesqueness. The finest and most animated part is St. Mark's place, about 575 ft. long and 185 to 270 ft. broad, containing the cathedral and the doge's palace, bordered by arcades, and surrounded by stately edifices. The Piazzetta or smaller square at the end of St. Mark's place extends to the principal quay (*molo*). At each end of the Rialto bridge are also open spaces, and on the top of the bridge are three busy passages, divided by rows of shops. But the only street worthy of the name is the Merceria, the great commercial thoroughfare, which is connected with the Rialto by intricate and overcrowded lanes.—Of the churches, the most important is St. Mark's, on the E. side of the square, which was formerly the ducal chapel, but is now superseded by San Pietro di Castello as the cathedral. The foundations of the present edifice were laid in 977. It is built chiefly in the Byzantine style, in the form of a Greek cross with the addition of large porticoes. Venetian vessels were obliged to bring from the East pillars and marbles for the edifice, the principal front of which has 500 columns of various shapes and colors. Over the central portal of the vestibule stand the celebrated bronze horses, brought from the hippodrome of Constantinople when that city was taken by the crusaders; they were carried to Paris by Napoleon, but restored in 1815. The cathedral is surmounted by five domes, the central one 90 and the others 80 ft. high. The interior is rather sombre, owing to the limited number of windows, but it is exceedingly rich, the walls and columns being of precious marbles, the pavement of tessellated marble, and the vaulting of mosaics upon a gold ground. Near the angle of the squares is the *campanile* or bell tower of St. Mark, where Galileo made many observations. It is a quadrangular mass of brick, 323 ft. high and 42 ft. square at the base, with a pyramidal pinnacle. There are altogether about 100 churches, and several synagogues. Santi Giovanni e Paolo, popularly called San Zanipolo, contains the monuments of many doges and other illustrious persons. Titian's "St. Peter Martyr," one of its greatest ornaments, was destroyed by fire in 1807. The Franciscan church (Sta. Maria Gloriosa de' Frari) contains the ancient archives and monuments of Titian and Canova. Sta. Maria della Salute possesses Titian's "Descent of the Holy Spirit," and since 1820 the remains of Sansovino. Il Redentore, on the Giudecca island, is regarded as Palladio's masterpiece. San Salvatore, near the Rialto bridge, possesses Titian's "Transfiguration," and splendid monuments by Sansovino, one of the chief architects of the building. Among other noteworthy churches are S. Giorgio Maggiore, S. Zaccaria, SS. Apostoli, S. Francesco della Vigna, S. Giorgio de' Greci, S. Jacopo di Rialto, Sta. Lucia, La Madonna dell' Orto, S. Casiano, de' Gesuiti (with the tomb of Manin, the last doge), S. Giobbe, Sta. Maria della Salute, S. Moise, and S. Stefano, the last being one of the finest in the pointed style. The adjacent island of San Lazaro has been since 1715 the principal seat of the Mekhitarist congregation of Armenian monks, established there by their founder; they are celebrated for editing Armenian works, and for generally promoting Armenian and European literature. (See MEKHITAR.) The doge's palace, built early in the 9th century, has been repeatedly destroyed, generally by fire. In the 14th century it was rebuilt by Marino Falieri. The present edifice dates from subsequent periods. It contains the magnificent hall of the great council, now used as offices of provincial authorities,



St. Mark's Place.

that of the four gates by Palladio, and that of the formidable council of ten, and other memorable rooms, with embellishments and works of art by the most illustrious masters. In the two lower stories are the cells described in the notes to the fourth canto of Byron's "Childe Harold," and at the top of the palace (*sotto piombi*, under the leads), exposed to scorching heat in summer and to cold in winter, languished for a long time political and other prisoners amid excruciating sufferings. Silvio Pellico was one of the last confined here. The famous bridge of sighs (*ponte dei sospiri*) connects the palace with the *carceri* (public prison), built in 1589 by Da Ponte. The original palace of the great judicial dignitaries of the republic, standing upon 50 arches and filling nearly the whole N. side of St. Mark's square, was converted into a royal palace by Eugène de Beauharnais; and one of Sansovino's grandest structures, the church of San Geminiano, was pulled down in 1810 for its extension. Pecht's *Kunstschätze Venedigs* (Trieste, 1858) contains engravings of all the masterpieces in the churches and palaces of Venice. Several of the palaces have been appropriated to various purposes, such as the Farcetti for the municipality and the Grimani for the post office. The latter is the finest modern palace, and the palazzo Vendramin Calerghi was regarded as the most superb in the 16th century. The modernized Manfrini palace once contained a picture gallery far superior to the present one. The *casa d'oro* was an oriental gilded palace of the 15th century, and was restored by Taglioni. The mint and custom house are notable public buildings, but the most impressive of all is the arsenal and dockyard, at the E. end of the city. It was long the most characteristic monument of the great naval power of the republic of Venice. Here are docks and basins, founderies for cannon, forges, an armory, a long ropewalk, and other works. New graving docks and a patent slip are nearly finished. The whole is surrounded by a lofty wall, extends over a circumference of nearly 3 m., and at one time employed 16,000 workmen. At the gate or land entrance are the marble lions brought from Greece at the end of the 17th century. The vessel (Bucentoro) which was annually used in the doge's so-called marriage with the Adriatic by throwing a ring into the sea, was destroyed by the French at the end of the 18th century, together with other relics in the model room. Adjoining the cathedral is a lofty tower (*torre dell' orologio*) with a remarkable clock, above the dial of which are two bronze figures popularly known as "Moors," striking the hours on a bell. At the S. end of the Piazzetta are two granite columns, which were surmounted by the winged lion of St. Mark, the emblem of the republic, and St. Theodore standing on a crocodile and bearing a shield and a sword. Among recent monuments are those of Daniele Manin and Goldoni, and one of Byron is projected.—Venice formerly possessed many *scuole*, lay charitable societies under ecclesiastical patronage; the principal one, that of St. Mark's, now forms part of the great city hospital. The educational institutions comprise, besides the new common schools, a naval college, a lyceum, several gymnasiums, new scientific and polytechnic government schools, and a chair for instruction in Japanese; and there are a museum of the natural sciences, an Athenæum, and a botanic garden. The library of St. Mark's is now in the doge's palace, and that endowed by Petrarch is in the royal palace. The academy of fine arts, in the former convent de la Carità and designed by Palladio, includes several schools and one of the largest and finest picture galleries in Italy. The municipal museum, founded by Count Correr, has also various works of art; and the pinacoteca Manfredini is in the ecclesiastical seminary connected with the church of Sta. Maria della Salute. Venice abounds with memories of Marco Polo, Petrarch, Titian, Tintoretto, and other illustrious men. The principal theatre is La Fenice, accommodating 3,000 persons. It was originally built in 1791, and rebuilt after the fire of 1836, and is now one of the finest opera houses in Italy.—Venice has always been celebrated for its glass pearls, beads, and other glass wares, made in the city and on the island of Murano. The ancient manufacture of brocade tapestry has recently been revived, and also that of the lace work, for which the adjacent island of Burano was always celebrated; and a new feature of industry is the imitations of antique furniture, made of pear wood and bone instead of the ebony and ivory formerly used. Among other manufactures are machines, iron and bronze work, gold and silver ware, optical instruments, photographs, and mosaics. The imports in 1873 amounted to $54,086,843, which was $30,685,926 more than in 1872; the increase was mainly due to that in the trade with India through the Peninsular and Oriental steamers, of which Venice has become an important station. They consisted chiefly of oils, grain, colonial goods and drugs, woven goods and twist, indigo, wine and spirits, silkworm eggs, hardware, timber, hides and leather, and cattle. The exports, valued at $46,999,712, comprised chiefly cotton, butter, grain, raw silk, colonial goods and drugs, textile fabrics and twist, glass beads and enamels, and hemp. The greater part of the trade is with England, Austria, the East Indies, and Japan; next in order of importance are the Turkish empire (including Egypt and Roumania), Holland, Sweden and Norway, and the United States. Venice is the principal market of the petroleum trade with this country, and the imports of that article in 1873 amounted to $704,262. The exports to the United States amounted in the year ending Sept. 30, 1874, to only $56,238 in gold. For the year ending Dec. 31, 1873, the arrivals comprised 439 steamers (203 Austrian, 141

English, 92 Italian, and 3 Dutch), tonnage 275,236, and 2,205 sailing vessels, tonnage 190,158; the departures were 440 steamers, tonnage 276,966, and 2,232 sailing vessels, tonnage 197,567. Venice was a free port for a considerable period prior to Jan. 1, 1874. The unfavorable results anticipated from the change have been in a great measure warded off by the general increase of prosperity owing to agricultural improvements in the interior, to the revival of old branches of industry, and to the greater transit and direct traffic with Egypt, India, China, and Japan, and other countries.—In the early part of the 5th century the Roman territory of Venetia (see VENETIA) was inhabited by a peaceful, prosperous, and commercial people. Aquileia, its capital, was one of the most flourishing cities of Italy, and it contained others which almost rivalled the capital. In 452 Attila invaded the country, burned its towns, massacred many of the inhabitants, and utterly destroyed Aquileia, which was rebuilt at a later period. (See AQUILEIA.) The fugitives from the cities settled on the islands in the lagoons and the gulf of Venice, and, together with the few earlier settlers, supported themselves by fishing and the manufacture of salt. Though professing allegiance to the western empire, they were practically independent, and were governed at first by three consuls elected by themselves. About 457 tribunes elected in the same manner were substituted for the consuls, a change more nominal than real, and the number of these was gradually increased to twelve. The islands, safe from outward attack, were frequently involved in quarrels with each other, until in 697 Cristoforo, patriarch of the island of Grado, proposed that in place of the twelve tribunes one common ruler should be elected for life with the title of duke (in the Venetian dialect *doge*), in whom all power should be vested. In March, 697, Paolo Luca Anafesto was chosen first doge. The families of the twelve deposed tribunes constituted a kind of aristocracy, and subsequently became such by law. The successive changes in the government of Venice, which ultimately degenerated into a terrible oligarchical rule, are noticed in the article DOGE. The seat of government, after being repeatedly changed from one island to another, was permanently fixed in 810 on the island of Rialto, which became a celebrated centre of trade, and it was speedily connected with adjacent islands by wooden bridges. After the fall of the western empire Venice at different times acknowledged allegiance to the Gothic kings, the eastern empire, and the emperors of Germany, but virtually she was independent. In 829, according to tradition, the bones of the apostle St. Mark were transferred from Alexandria to Venice, and he became the patron saint of the republic, which was often styled the "republic of St. Mark." The influx of pilgrims to the shrine of the saint added to the wealth of the city; her commerce increased, and from this time until the beginning of the 16th century she continued to grow in population, wealth, and refinement. Previous to the first crusade in the latter part of the 11th century she had, by conquest, by voluntary submission, or by cession from the eastern empire, acquired territory on the mainland of Italy and in Dalmatia, Croatia, and Istria, on the opposite shores of the Adriatic, and had established commercial relations with the principal nations. Throughout a great part of the eastern empire her traders were exempted from all duties and imposts, and most of the carrying trade of the world was in her hands. In 1098 she sent a great fleet to the assistance of Godfrey of Bouillon; but it contributed more to the extension of her trade and the securing of commercial privileges in the East than to the rescue of the holy sepulchre. She joined the Lombard league against the German emperor, and in 1177 gained a great victory in defence of Pope Alexander III. over the fleet headed by Otho, son of Frederick Barbarossa. In gratitude for this victory the pope gave the doge Ziani a ring and instituted the ceremony of "marrying the Adriatic." Frederick was forced to consent to a congress at Venice, at which peace was concluded. In 1202 the soldiers of the fourth crusade assembled at Venice. Unable to pay in money for their transportation to the East, they consented to assist the Venetians in suppressing an insurrection in Dalmatia, and then under the lead of the doge Enrico Dandolo stormed Constantinople, to avenge Venice for the deprivation of some of her commercial privileges. (See DANDOLO.) The fairest portion of the eastern empire, including parts of the Peloponnesus, Crete, Eubœa, and other islands, now fell under the sway of Venice, and she was the most splendid city in Europe. The spoils and the trade of the East enriched the city, and especially the nobility, who erected magnificent palaces filled with the choicest works of art. In 1289 the inquisition was established, but it was always kept in subjection to the civil power. After some minor conflicts with Genoa, a serious war broke out on the occupation of Constantinople by the Palæologi with Genoese aid (1261); and until near the end of the 14th century the two republics were often engaged in desperate struggles, and Venice was once brought to the verge of ruin. (See GENOA.) Among the internal convulsions during this period, the conspiracy and execution of the doge Marino Falieri in 1355 is chiefly remarkable. (See FALIERI.) But Venice soon recovered from her losses, and on the death of the doge Tommaso Mocenigo in 1423 she had reached the climax of her prosperity. During the period of her struggles with Genoa, she had made herself mistress of Treviso and other territories on the Italian mainland, and after the peace of 1381 also of Vicenza, Verona, and Padua. Under Mocenigo's successor Francesco Foscari (see Foscari) she was engaged for about 30 years in mostly successful wars with the dukes of Milan, and for the remainder of the century with the Turks, with whom a disadvantageous peace was concluded in 1503. During the 16th and 17th centuries Venice was continually at war. Alliances were formed and dissolved at short intervals, so that from the formation of the league of Cambrai against Venice in 1508, between the pope, the emperor of Germany, and the kings of Aragon and France, till the conclusion of the peace of Carlovitz in 1699 between the Turks and the Christians, Venice was at different times engaged in war both for and against nearly every power in Europe. A portion of her Grecian possessions were taken by the Turks in a war which ended in 1540, and Candia, after a long struggle, in 1669; and in 1715 her last hold on the Morea was lost. The discovery of America and of the passage around the cape of Good Hope had in the mean while diverted enterprise and commerce into new channels, and Venice, after being for centuries the centre of the trade between Asia and Europe, gradually declined. With the exception of unimportant contests with the piratical sovereigns of Tunis and Algiers, she remained at peace during the greater part of the 18th century. During the wars which followed the breaking out of the French revolution Venice declared her neutrality; but her hostility to France continually manifested itself, and finally Bonaparte declared war against her, and she was compelled to yield. In May, 1797, the French troops took possession of the city, which no hostile force had ever before entered. The hereditary privileges of the aristocracy were abolished; the great council was superseded by a provisional government; the destruction of the prisons and other buildings of the inquisition was decreed; the "golden book," containing the names of the hereditary nobility, was burned, and Venice lost her independence. By the peace of Campo Formio Venice with a large part of her territories was subjected to Austria. By the peace of Presburg in 1805 she was annexed to the kingdom of Italy. After the fall of Bonaparte she again passed under the dominion of Austria, forming a part of the Lombardo-Venetian kingdom. During the revolutionary movements of 1848 Venice in March revolted against the Austrian rule and proclaimed the restoration of the republic (see Manin); but after enduring a long siege and a terrible bombardment, she capitulated on Aug. 23, 1849, and on the 30th Radetzky entered the city, which was not released from the state of siege until May 1, 1854. By the peace of Villafranca in 1859 Venice was still left in the possession of the Austrians. After their defeat in the Austro-Prussian war of 1866 Venice and such of her former territories as were under Austrian rule were ceded to Napoleon III.; he immediately placed the government in the hands of the municipal authorities, who at once called upon the people to vote on the question of annexation to the kingdom of Italy. The election was held in October, and out of upward of 650,000 votes cast all but 69 were in favor of annexation. Victor Emanuel made his entrance into Venice Nov. 7. The emperor Francis Joseph of Austria met Victor Emanuel, for the first time after his loss of the dominion, at Venice, April 5, 1875.—See Tentori, *Saggio sulla storia di Venezia* (12 vols., Venice, 1785–'90); Count Daru, *Histoire de la république de Venise* (7 vols., Paris, 1819–'21); Philippi, *Geschichte des Freistaats Venedig* (3 vols., Dresden, 1828); *Venezia e le sue lagune* (3 vols., Venice, 1847); Ruskin, "The Stones of Venice" (3 vols., London, 1851–'3); Romanin, *Storia documentata di Venezia* (10 vols., Venice, 1853–'61); W. C. Hazlitt, "The History of the Venetian Republic" (4 vols., London, 1858–'60); Howells, "Venetian Life" (New York, 1866); Cicogna, *I dogi di Venezia* (2 vols., Venice, 1867); and Billitzer, *Geschichte Venedigs* (Trieste, 1871).

VENICE, Gulf of, the name given to the N. W. part of the Adriatic sea, where it forms an indentation in the coast of Venetia, extending about 50 m. from the mouth of the Tagliamento to the delta of the Po. The gulf of Trieste is its N. E. prolongation. Its depth is not more than 12 fathoms. It receives the waters of the Piave, Brenta, Adige, Po di Levante, Po della Maestra, and other rivers.

VENLOO, a fortified town of the Netherlands, in the province of Limburg, on the right bank of the Maas, 40 m. N. N. E. of Maestricht; pop. about 8,000. It has a large Catholic church, a fine town hall, two arsenals, a school of industry and design, manufactories of tobacco and other articles, tanneries, breweries, and distilleries, and much trade in hogs. A suspension bridge connects the town with Fort St. Michael on the left bank of the Maas; on the right bank is Fort Ginkel, and opposite Venloo is the fortified island of Waert or Weert. The place has undergone many sieges.

VENOM, a kind of secretion produced in certain animal bodies, which acts as a poison when introduced into the tissues of other animals. The characteristics of a venom, as distinguished from poisons in general, are that it is of organic origin, produced in special secreting organs, termed "poison glands," and that it is introduced into the tissues by means of certain organs specially adapted for the purpose, which have the form of stings or fangs. Thus we have the venom of the rattlesnake, the viper, the scorpion, and the tarantula. A virus, on the other hand, though also a poison of an organic, and usually an animal origin, is the result of diseased action or of putrescence, and usually has the power of exciting in the poisoned individual the same disease as that by which it was itself produced. Thus we speak of the virus of smallpox, of cowpox, and the like. The poison of hydrophobia is properly not a venom but a virus, since it is due to the presence of a diseased element in the natural secretion of the saliva, and reproduces the same disease by inoculation. A virus does not usually cause any local irritation; or if so, as in the case of cowpox or smallpox, it is quite insignificant as compared with the effect upon the system at large. A venom, on the other hand, generally produces great pain, swelling, and inflammation at the spot where it is applied; and its constitutional effect appears to be in great measure sympathetic with the local disturbance.

VENTILATION. See WARMING AND VENTILATION.

VENTRILOQUISM (Lat. *venter*, the belly, and *loqui*, to speak), a kind of vocal mimicry, by which an illusion is produced in relation to the source or direction from which the sound proceeds. The name, or at least its cognate terms in Greek and Hebrew, originated from the practice of the witches and persons supposed to have a familiar spirit among the Canaanitish nations and the Jews, and the diviners or prophesying priests and priestesses of the Greeks, causing the answers to the questions asked by those who consulted them to proceed apparently from the abdomen, in which, as they alleged, resided their familiar spirit or demon. The first attempts at ventriloquism were probably made in Egypt or India, in both of which countries it has been known from the earliest periods. That it was commonly practised in Egypt during the residence of the Israelites there is evident from the prohibitions of the Jewish lawgiver against it after the exodus, in Lev. xix. 31, and xx. 6, 27, and Deut. xviii. 10–14. The early inhabitants of Canaan had also practised it, as appears from the last passage named. In all these cases the term translated "having a familiar spirit" signifies in the original "speaking from the belly." Notwithstanding the death penalty pronounced against it, the practice of divination or ventriloquism continued among the Jews, as the references to it in Isaiah and the other prophets fully demonstrate. Nor did it cease as a pretended means of revelation in the early centuries of the Christian era, as the case in Acts xvi. 16, the well known practice of gastromancy among the later Greeks, and the repeated references of St. Chrysostom and other early Christian fathers, sufficiently prove. Its use for such purposes was finally abandoned during the middle ages. In the early part of the 16th century Louis Brabant, valet de chambre of Francis I., employed it to secure the consent of the mother of his betrothed to his marriage with her daughter, and also to extort from a rich miser a large sum of money. In 1772 the abbé de la Chapelle published an account of two eminent ventriloquists, Baron Mengen at Vienna and M. Saint-Gille near Paris, who were very successful in producing illusions by means of vocal mimicry, and causing the voices which they imitated to appear to come from trees, the earth, or the bodies of animals. These gentlemen made no secret of their performances, but attributed their skill to their fondness and talent for mimicry, which enabled them to imitate accurately all kinds of sounds. M. Saint-Gille displayed his skill before commissioners of the French academy of sciences, who investigated the subject with great care. Since that period ventriloquism has become common, and most of the so-called magicians, wizards, and sleight-of-hand performers practise it. Thiernet, Borel, Fitzjames, Houdin, and Alexandre in France, and Charles Mathews and others in England, enjoyed a high reputation for their success in this art. M. Comte, a celebrated French ventriloquist, was the first to demonstrate the possibility of cultivating it by scientific methods, and several eminent singers have resorted to it to produce unusual musical effects. It was supposed for many years, and eminent physiologists gave countenance to the theory, that some peculiarity in the conformation of the larynx was requisite for ventriloquism, or at least that it was accomplished by processes essentially different from those adopted in ordinary speaking or singing; but it has been demonstrated that the vocal organs of the ventriloquist are the same as those of other men, nor is his use of them materially different from that of others. For success in his art, he requires only keen perceptions, an ear delicately attuned to the variations of sound produced by distance or direction, and a strongly developed mimetic faculty. The vocal organs have the power of imitating under skilful training all the sounds of animate or inanimate life, and in such a way as to represent them as heard at greater or less distances and from different directions. The ventriloquist is well aware that no one of our senses is more easily deceived than that of hearing, because in listening to sounds we judge of their remoteness by comparing them with other sounds whose distance we are familiar with, and determine their distance by an arbitrary and often incorrect estimate of their relative volume at the place of their supposed emission. Aware of this, he utters the sound with the effect it would have upon the hearer's ear if it had really traversed the distance he designs it to represent, reducing its loudness, softening somewhat its quality or tone, and, if it is in words, obscuring a little the consonant sounds, while retaining unaltered the pitch and duration. In doing this, he modifies the tones of his voice by varying the position of the tongue and the soft palate, dilating or contracting the mouth or pharynx, and either dividing the buccal and pharyngeal cavities into several compartments or throwing them into one. This is done without movement of the lower jaw and with but slight motions of the lips, while by means of skilful and apparently natural gestures the attention of the hearer is diverted from the ventriloquist himself to the point from which the voice or sound is supposed to proceed. Usually the ventriloquist stands so as to give only a profile view of his face, unless at a distance from his audience, and thus has greater opportunity of concealing any slight motions of the facial muscles. In most cases, too, the apparently remote voice is a falsetto, this being more within the command of the performer, without perceptible facial movement, than the natural tones. (See VOICE.)

VENTURA, a S. W. county of California, bordering on the Pacific ocean, and drained by Buenaventura and Santa Clara rivers; area, about 2,000 sq. m. It has been formed since the census of 1870. The surface is generally mountainous. The valleys are very fertile. Cattle and sheep are largely raised, and Indian corn, barley, grapes, oranges, and other semi-tropical fruits are grown. Various minerals are found. Capital, San Buenaventura.

VENTURA DE RAULICA, Gioacchino, an Italian pulpit orator, born in Palermo, Dec. 8, 1792, died in Versailles, Aug. 3, 1861. He was educated in the Jesuit college of Palermo, and entered the society of Jesus, but left it to become a Theatine. His first pulpit discourses marked him as one of the greatest orators in Italy. He became general secretary of his order, contributed largely to its restoration, and published *La causa dei regolari al tribunale del buon senso.* Subsequently he was named censor of the press and member of the royal council of public instruction for the kingdom of Naples, and used his influence to introduce into Italy the new traditionalist philosophy of France. He became especially distinguished for his funeral orations. In 1824 he was appointed general of the order of the Theatines, and fixed his residence at Rome, where he was made a member of a commission of censorship; at the same time he was presented to the chair of ecclesiastical law in the university of Rome, and soon after made almoner of the same institution. He was prominently employed in diplomatic affairs. In 1828 he published *De Methodo Philosophandi*, in defence of the scholastic philosophy. This was bitterly attacked by the abbé Lamennais; and, wearied of the controversies which ensued, Ventura quitted the pontifical court, and spent ten years in retirement. In 1839 appeared his work *Delle bellezze della fede* (3 vols. 8vo). During this period also he preached his finest sermons in the church of S. Andrea della Valle and at St. Peter's, and his published homilies fill 5 vols. 8vo. After the death of Gregory XVI. he exerted himself to secure the election of Cardinal Mastai-Ferretti, and became one of the private counsellors of the new pope. In 1847 he preached the funeral sermon of O'Connell, the liberal opinions advanced in which gave him great influence with the people. At the beginning of 1848 the popular government of Sicily made him minister plenipotentiary and commissioner extraordinary to the court of Rome. He published a treatise "On the Independence of Sicily," another "On the Legitimacy of the Acts of the Sicilian Parliament," and subsequently an octavo volume entitled *Mensonges diplomatiques.* He also labored with Gioberti and Rosmini to effect a commercial union of the Italian states as a first step toward a political confederacy. On May 4, 1849, he retired under the protection of the French to Cività Vecchia, and afterward to Montpellier in France. There he wrote "Letters to a Protestant Minister" (12mo, 1849), in answer to a clergyman of Geneva, who maintained that St. Peter had never been in Rome. After remaining two years at Montpellier he went to Paris, where he drew crowds to the churches of the Madeleine and St. Louis d'Antin. He published there *Histoire de Virginie Bruni* (12mo, 1850); *Les femmes de l'Évangile* (12mo, 1852); *La raison philosophique et la raison catholique* (8vo, 1852); *Essai sur l'origine des idées* (8vo, 1853); *La femme catholique* (3 vols. 8vo, 1854); *L'école des miracles, ou les œuvres de la puissance et de la grandeur de Jésus-Christ* (2 vols. 18mo, 1854–'5); and *Le pouvoir chrétien* (8vo, 1857).

VENUS, in Roman mythology, the goddess of love, especially of sensual love. She was originally considered a divinity of very little importance, and no mention was made of her in the documents relating to the early history of Rome. In later times the Romans identified her with the Greek Aphrodite, and adopted all the myths relating to that goddess. Aphrodite was among the Greeks one of the great Olympian divinities and the goddess of love and beauty. The Iliad makes her the daughter of Jupiter and Dione; later traditions assign to her a different parentage. The one most generally adopted, because best suited to the poetical imagination of the Greeks, represented her as having sprung from the foam of the sea, whence her name, from the Greek ἀφρός, foam. She first landed at Cythera, and thence went to Cyprus. Wherever she trod, flowers sprang up. These two islands were the principal seats of her worship, and from them she was called the Cytherean, Paphian, and Cyprian Aphrodite. She was married to the deformed god Hephæstus (Vulcan), but had many amours both with other gods, especially Mars, and with mortals. Of the latter, Adonis inspired her with the fondest passion. To the Trojan Anchises she bore Æneas, from whom the Roman poets and historians traced the descent of Romulus. Paris awarded her the golden apple, the prize of beauty, in preference to Juno and Minerva; and she consequently sided with the Trojans in the war against their city. She had a *cestus* or girdle which inspired the beholder with a passionate love for the one who wore it. Among plants and birds, the poppy, apple, myrtle, and rose, and the sparrow, swallow, swan, dove, and lynx or wryneck, were her favorites. The planet Venus and the month of April were sacred to her. Young animals were sometimes sacrificed to her, but usually the offerings consisted of incense and garlands of flowers. Festivals were celebrated in her honor, the principal of which were called *Aphrodisia.* Modern scholars regard Aphrodite as originally identical with the Phœnician Astarte (in the Bible Ashtoreth), or with Baaltis (by some identified with the Asherah of the Bible), and think that her worship was introduced at a very early period by the Phœnicians into Cyprus and Cythera, whence it spread over Greece, and in the course of its development became wholly Grecian.—Venus was a favorite subject of ancient sculpture. The statues known as the Venus de' Medici and the Venus of Milo are among the most celebrated works that have been preserved from antiquity. The former, exhumed in the 17th century in 11 pieces, is in Florence; the latter, found in the island of Milo in 1820, is in the Louvre, in Paris.

VENUS, the second planet in order of distance from the sun. According to the estimate of the sun's distance used throughout this work (91,430,000 m.), Venus travels at a mean distance from the sun of about 66,134,000 m. The eccentricity of her orbit is small, not exceeding 0·00686, so that her greatest distance, 66,586,000 m., does not exceed her least distance, 65,682,000 m., by more than about 900,000 m. In estimating her greatest and least distances from the earth, accordingly, it is more important to notice the effect of the earth's variation of distance, which amounts (see EARTH) to about 3,000,000 m. The actual point of nearest approach between the two orbits lies in longitude about 70°, and here the orbits are about 24,150,000 m. apart; this then is the nearest approach Venus can ever make to the earth. The orbits are furthest apart in about longitude 250°, where they are separated by about 26,500,000 m.; and adding to this the diameter of Venus's orbit, about 132,300,000 m., we find the greatest distance separating the two planets to be about 158,800,000 m. The mean inclination of Venus's orbit to the ecliptic is about 3° 23′ 31″; but her path is not so largely inclined to the mean plane of the solar system. Her mean sidereal revolution is completed in 224·700787 days, and her mean synodical revolution in 583·920 days. Her diameter is about 7,510 m.; her volume 855 thousandths of the earth's, her mass about 885 thousandths (her density exceeding the earth's in the proportion of 103 to 100). Venus, travelling on a path within the earth's, is never seen in opposition, passing between the earth and sun when at her nearest. At this time she is of course invisible, her dark hemisphere being turned toward the earth. On the other hand, when she turns her fully illuminated hemisphere toward the earth, she is not only at her furthest, but lies almost directly on the prolongation of a line directed toward the sun, and is therefore lost in his superior lustre. Between these phases she exhibits all the figures shown by the moon, passing from a nearly full disk to the finest crescent (as an evening star), and from finest crescent, after her disappearance in inferior conjunction, to nearly a full disk (as a morning star), when she again disappears in superior conjunction. But as her distance from the earth, unlike the moon's, undergoes great variations, she varies in apparent size as well as in phase, having the least diameter when nearest to a full orb, and the greatest when her crescent of light is finest. She lies furthest from the sun in the heavens when her disk is about half illuminated, the distance (her elongation, as it is called) varying in different synodical revolutions from about 45° to about 47° 12′.—Although this planet approaches the earth so much more closely than her rival in beauty, Jupiter, it has not been found possible to examine her surface with the telescope to any very useful purpose. Her great brightness introduces a difficulty which does not exist in the case of Jupiter, closely though he resembles her in appearance when both are seen under like conditions with the unaided eye; for the illumination of Venus exceeds that of Jupiter (mile for mile of surface) fully 48 times, though the intrinsic brilliancy of Venus does not surpass Jupiter's much more than 20 times. It is singular that, notwithstanding this difficulty, the first observers with the telescope achieved considerable success in recognizing and watching spots on her surface. In fact, the best telescopes of modern times fail to show spots which Cassini, Bianchini, and others of the early observers agree in describing. If the earlier observers had deduced different rotation periods, we should be led to conclude that the spots they saw had no real existence; and this indeed has been the general conclusion to which modern astronomers have been led. Yet it should be noted that in presence of the close agreement between the rotation periods deduced by Cassini, Schröter, and De Vico, it is difficult to reject altogether the evidence which led to such closely accordant results. Domenico Cassini, after long seeking in vain for recognizable marks, noted in 1667 a bright spot not very far from the southern horn of the planet; and from observations of this spot he deduced a rotation period of about 23 hours. In 1726 Bianchini made observations whence he deduced the monstrous period of 24 days 8 hours. (It was on this rotation period that Ferguson based his remarkable account of the diurnal phenomena of Venus.) The younger Cassini, having carefully compared his father's observations with Bianchini's, found that both series could be explained by a rotation period of 23 hours and between 21 and 22 minutes, whereas a period of 24 days 8 hours could not be reconciled with D. Cassini's observations. This explanation was received, because it was known that Bianchini's observations were not continuous, but interrupted for want of sky room, a neighboring building interfering with his view of the planet. Schröter's observations led to the rotation period 23 h.

21 min. 19·2 sec. They were made on a mountain (or what he took to be such) near the southern horn of Venus. He remarked that while the northern horn always preserved its proper pointed figure, the southern sometimes appeared rounded, which circumstance he considered due to the presence of a mountain whose shadow fell on the place where the horn should have been. Beyond this place he observed a luminous point which he regarded as the summit of another mountain, illuminated by the sun. The proper position for showing these appearances cannot be long maintained, as the planet rotates, and thus their recurrence affords a means of determining the rate of its rotation. By taking as many as 160 rotations, Schröter deduced the rotation period mentioned above. De Vico at Rome, in 1839–'41, made a series of observations, confirming Bianchini's drawings in a remarkable degree. He deduced the rotation period 23 h. 21 min. 22 sec. Accepting this result, we find for the three planets Venus, the earth, and Mars, in this order (the order of their distances), the rotation periods 23 h. 21 min. 22 sec., 23 h. 56 min. 4 sec., and 24 h. 37 min. 23 sec., increasing with distance from the sun in a nearly uniform manner.—While, as we have said, it seems impossible to reject the evidence afforded by the observations of Schröter, De Vico, and others, in favor of the existence of recognizable marks on Venus, yet as many of the ablest observers, using the finest telescopes of our day, have failed to recognize such spots, we must adopt Sir John Herschel's explanation, who says that "the most natural conclusion from the very rare appearance and want of permanence of the spots is, that we do not see, as in the moon, the real surface of the planet, but only its atmosphere, much loaded with clouds, serving to mitigate the otherwise intense glare of the sunshine." It is clear from other circumstances that Venus has an atmosphere. During her transits over the sun's disk in 1761 and 1769 a sort of penumbral light was observed round her disk. Wargentin observed that the part of the disk off the sun could be recognized by a faint light bordering it, during almost the whole time of emersion. Bergman, who observed the transit of 1761 at Upsal, states that at ingress the part of Venus still off the sun could be seen, being bounded by a crescent of light. At the egress this appearance was even more remarkable. As more of the planet's disk passed off the sun's, the part of the crescent of light furthest from the sun grew fainter and ultimately vanished, so that at last only the horns could be seen. Many other accounts of these two transits contain similar statements, and during the recent transits the same appearances were seen by many observers. It is readily perceived that such appearances might be expected in the case of a planet surrounded by an atmospheric envelope. The sun would be raised by atmospheric refraction precisely as our own sun is raised above the horizon after he has really passed below it. When we look at the part of Venus furthest from the sun, before immersion or after emersion (at a transit), we are looking in the same direction as an observer of Venus at that part who should direct his gaze sunward. As he would see the sun raised above the horizon by atmospheric refraction, though really below, so we see the sun doubly raised because the line of sight passes through the hither half as well as the further half of the atmosphere above that part of Venus. In other words, though the outline of the sun's disk is really (that is, in a geometrical sense) behind the disk of Venus, we receive actual sunlight round even the part of Venus's disk remotest from the sun; *a fortiori* then is sunlight received round the remaining part of Venus's disk which lies outside the sun's. Hence an arc of light, brightest near the cusps of Venus, but visible (soon after immersion begins and again till near the end of emersion) at the part of Venus remotest from the sun. Prof. Lyman of Yale college has even seen this light at the part remotest from the sun, when the whole disk of Venus has been off the sun's, as at inferior conjunctions where there has been no transit. From such an observation it may be inferred that the atmosphere of Venus is deeper than our own. For we can infer from Bergman's observations a horizontal refraction scarcely less than that of our own atmosphere; and Lyman's observation would imply an atmospheric refraction nearly twice as effective. The atmosphere of Venus has been analyzed with the spectroscope by Huggins, Vogel, and others, and the presence of aqueous vapor is held to have been demonstrated by the observations; yet it was not until the transit of 1874 that this point was in reality established. On that occasion Tacchini's observations seemed to demonstrate the fact that there is water on Venus.—A curious question is raised by the apparently strong evidence obtained during the 18th century to show that Venus is accompanied by a satellite. It is quite certain now that no such satellite exists, yet several skilful observers not only imagined that they perceived such a satellite, but even assigned to it a definite period of revolution around its primary. During the transits of 1761, 1769, and 1874, it was conclusively shown that no such body exists, but the difficulty of accounting for the apocryphal observations remains as great as ever.—Thirteen sidereal revolutions of Venus are completed in a period very nearly equal to eight sidereal years. Hence at every fifth conjunction the planets return nearly to the same longitude. Accordingly the perturbing effects taking place at one conjunction are repeated at the fifth conjunction thereafter, and so on. Consequently there is an accumulation of perturbations, resembling the great inequality of Saturn and Jupiter, though far less remarkable in amount. It has for its period about 240

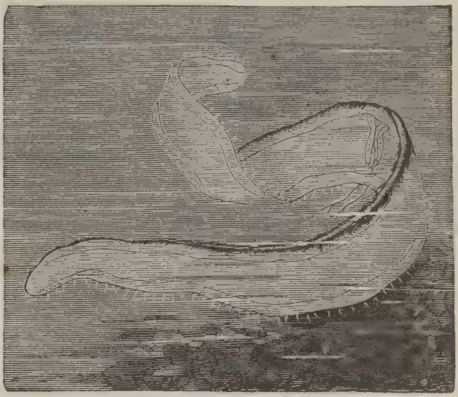
years. The greatest acceleration and retardation of either planet amount only to a few seconds of arc. (For transits of Venus, see supplement, and the article TRANSIT.)

VENUS'S FLOWER BASKET, the common name of the *euplectella speciosa* (Gray), a very beautiful silicious sponge, found among the Philippine islands. The animal framework or skeleton, which in the living specimen is covered with the usual fibro-gelatinous substance of the sponges, is made up of silicious fibres, running from base to top, surrounded by smaller ones, forming open meshes resembling a basket or network, or delicate lace-like fabric. It is of a regular cornucopia shape, from 6 to 15 in. high, about an inch in diameter at the base, which is attached to some submarine object, gradually increasing to nearly 2 in. at the top; it is surmounted by a ridge about a quarter of an inch wide, and is closed above by a delicate network; the shape is very elegant, and the structure light. It sometimes encloses a hermit crab, which has entered for protection and been covered in by the growing sponge. By immersing the sponge in a dilute solution of chloride of soda or lime, the gelatinous film is removed, and the lace-like structure of pure silex is left untouched. The first specimen obtained was valued at over $150, but now they cost only a few dollars.

Venus's Flower Basket (Euplectella speciosa).

VENUS'S FLY TRAP. See DIONÆA.

VENUS'S GIRDLE, the common name of the *cestus Veneris* (Les.), an acaleph or jelly fish of the order of *ctenophoræ* or beroid medusæ, allied to *pleurobrachia.* (See CTENOPHORÆ.) It is gelatinous and free-moving, but elongated in a direction at right angles to the alimentary canal, forming a ribbon-shaped body 4 or 5 ft. long and 2 or 3 in. high; the edges are provided with vibratile cilia; the mouth is below and in the median line. It is common in the Mediterranean, near Naples, appearing at night like a band of phosphorescent flame.



Venus's Girdle (Cestus Veneris).

VERA CRUZ. I. A state of Mexico, bounded N. W. by San Luis Potosí, N. by Tamaulipas, E. by the gulf of Mexico, Tabasco, and Chiapas, S. W. by Oajaca, and W. by Puebla and Hidalgo; area, 27,433 sq. m.; pop. in 1873, 459,262. Capital, Jalapa. It is traversed by the Sierra Madre, and is generally mountainous, excepting the sandy coast region, about 30 m. wide. The highest peak is Orizaba or Citlaltepetl (Star mountain), 17,176 ft. high, on the border of Puebla. The Cofre de Perote, near Jalapa, is 14,309 ft. high, and San Martin or Tuxtla 9,708 ft. All of these are volcanoes, and Orizaba is perpetually snow-capped. The principal rivers are the Pánuco, Alvarado, and Coatzacoalcos, the mouths of all of which are obstructed by sand bars. There are several large lagoons on the coast, of which Tamiagua is about 60 m. long and 20 m. broad. Alvarado, the largest in the south, is divided into smaller lagoons by many islands. The climate is hot (80° to 85°) and insalubrious on the coast, where yellow fever prevails from May to November; but in Jalapa, Córdoba, Orizaba, and other elevated places, it is agreeable and healthful. The soil of the interior is very fertile, and produces, according to elevation, a vegetation ranging from tropical almost to arctic. Sugar is cultivated in all of the 18 cantons, coffee in 15, tobacco in 14, cacao in 11, and vanilla in 5. Cotton also is extensively cultivated, as well as the cereals and fruits. The coffee is very fine, and the tobacco is said to equal the Cuban. Cattle are raised in great numbers. Among the mineral products are gold, copper, lead, and iron. The total value of manufactures in 1873 was $2,374,400, the principal products being woollen and cotton cloths. In 1875 there were 528 public schools in the state, with an aggregate attendance of 19,702, 18 colleges or grammar schools, 6 schools attached to state prisons, and a military school. Vera Cruz is divided into 18 cantons: Acayucan, Chicontepec, Coatepec, Córdoba, Cosamaloapan, Huatusco, Jalapa, Jalacingo, Minatitlan, Mizantla, Orizaba, Papantla, Tampico, Tantoyuca, Tuxpan, Tuxtla, Vera Cruz, and Zonzolica. **II.** A city of the preceding state, in a marshy plain on the shore of the gulf of Mexico, lat. 19° 11′ 56″ N., lon. 96° 8′ 36″ W., 190 m. E. S. E. of the city of Mexico; pop. about 10,000. It is built in a semicircle fronting the sea, and is enclosed by a wall 6 ft. high and 3 ft. thick, and defended by two redoubts on shore and the castle of San Juan de Ulua or Ulloa, which stands on an island of the same name about half a mile from the shore. The streets are regular and wide, and form 66 squares, and some of those running E. and W. have a stream in the middle. The houses are strongly built of coral limestone, in the old Spanish style, enclosing a square court with covered galleries. Most of the windows are furnished with iron gratings, and window glass is not common. Among the principal buildings are the municipal palace, built in 1609, custom house, provincial treasury, commandant general's office, and the old convent of San Francisco, the tower of which was fitted as a lighthouse in 1872. In the same building is the public library, founded in 1870. There are also several churches, a theatre, bull ring, exchange, casino, three hospitals, and an artillery school. The city is lighted with gas, is supplied with water from the river Jamapa, and has a horse railway. The harbor is merely an open roadstead between the city and the castle, and is very insecure. A new mole was finished in 1875, but it is unapproachable during northers by any but small boats. On one of the bastions of San Juan de Ulua is a lighthouse, and on another a watch tower. There are also a chapel and a cemetery on the island. Besides this island there are in the roadstead a small island called Verde, and the Sacrificios and Blanquilla isles. Vera Cruz is the most important port of the republic; its exports amount annually to about $25,000,000, and its imports to $26,000,000. Of the latter, about $2,000,000 are from the United States. During the year ending June 30, 1874, 3,449 vessels entered the port, of which 2,278 were engaged in the coasting trade. The chief exports are coffee, vanilla beans, hides, tobacco, cochineal, caoutchouc, jalap, fustic, and indigo. Smuggling is common, and the official commercial returns seldom amount to more than half the real value of the trade. Vera Cruz is connected by railway with Mexico, with Medellin, and with Jalapa and Boca del Potrero, and by steamers with New York, New Orleans, the West Indies, and Europe.—The city of Villa Rica de Vera Cruz was founded by Cortes in 1519, a short distance N. of the present site; but it was abandoned in a few years for a position near the mouth of the Antigua, which was called Antigua Vera Cruz. About 1590 it was again removed to the present site and named Nueva Vera Cruz. Philip III. conferred on it the title and privileges of a city in 1615. The castle of San Juan de Ulua, which was the last foothold of the Spaniards in Mexico, was surrendered by them to the patriots in 1825. In 1838 Vera Cruz was bombarded and taken by the French, and in 1847 by the Americans under Gen. Scott. It surrendered to the allied British, French, and Spanish squadron

Vera Cruz.

in December, 1861, and was restored to Mexico in 1867.

VERATRINE, or **Veratria,** an organic base discovered in 1818 by Meissner in sabadilla seeds, *veratrum sabadilla*, and soon afterward by Pelletier and Caventou in white hellebore, *veratrum album.* It probably exists also in other species of *veratrum.* It is prepared by dissolving the alcoholic extract of the seeds in sulphuric acid. The solution is then treated with animal charcoal, and the veratrine, together with sabadilline, precipitated by an alkali. The precipitate is then again dissolved in dilute sulphuric acid, and nitric acid is added as long as it produces a black pitchy precipitate. To the filtrate dilute potash solution is added, again precipitating the veratrine, which is then washed and dried and dissolved in absolute alcohol. The alcoholic solution is then evaporated; the residue is boiled in water, the impure veratrine which remains is dissolved out by ether, and the ethereal solution on evaporation leaves the pure base veratrine. Delondre prepares veratrine by treating the crushed sabadilla seeds with very dilute hydrochloric acid in a displacement apparatus, precipitating the solution with slight excess of potash, and slightly heating the washed and dried precipitate with twice its weight of ether for four hours in a closed vessel provided with a safety tube. The ethereal solution on evaporation leaves pure veratrine.—Veratrine is ordinarily a white or whitish green crystalline powder, but by slow evaporation of its alcoholic solution it may be obtained in long prisms with a rhombic base. It is inodorous, but a minute quantity inhaled by the nostrils produces violent sneezing and headache. It is very acrid and poisonous, producing vomiting and purging when taken internally. It has a peculiar influence on the nervous system. Dr. J. L. Van Praag, in extensive experiments on the lower animals, found that it lowered the circulation and respiration, diminished the irritability of many of the nerves, and produced muscular relaxation, and in larger doses vomiting and purging. The secretion of saliva was much increased, but the urine was little affected. In poisonous doses the depressing effects were preceded by an accelerated pulse and respiration, and tetanic muscular spasms, followed by a characteristic dancing movement. It is used in medicine, both externally and internally. The diseases in which it has been employed are chiefly gout, rheumatism, neuralgia, dropsy, and functional diseases of the heart. Prof. Vogt of Bern employs it in pneumonia, in doses of about $\frac{1}{30}$ of a grain every two hours, gradually increased to ten times that quantity. It has also been employed in various nervous affections, as whooping cough, epilepsy, hysteria, and disorders caused by spinal irritation. From $\frac{1}{12}$ to $\frac{1}{6}$ of a grain may be given in the form of a pill, repeated every three or four hours, till its effects are produced. The tartrate, sulphate, or acetate may be used. Veratrine is much more employed externally than by the stomach, and is applicable in this way to all the complaints already mentioned. It is used as a local application in chronic swellings and indurations of the joints, whether from rheumatism, scrofula, or sprains. It may be used dissolved in alcohol, or rubbed up with a little lard in the proportion of from 5 to 20 grains to the ounce.

VERATRUM. See HELLEBORE.

VERBENA (Lat. *verbenaca*, vervain, from *verbenæ*, sacred boughs), the botanical and common name of a very large genus of herbs and shrubs, abundant in tropical countries; also called vervain, and in France *verveine.* The genus gives its name to a family, the *verbenaceæ*, which is closely related to the labiates, the most important difference being that in this the ovary is entire with the style attached at the top; the plants are generally without the aromatic qualities of the labiates. The teak tree (*tectona*) is an important member of the family. The verbenas have opposite, often much divided leaves; the flowers sessile, in bracted spikes, or in a flat cluster which elongates after flowering; calyx five-toothed; corolla tubular, often curved, with a spreading, rather unequally five-cleft limb; the included stamens four; the fruit when ripe splitting into four one-seeded nutlets. Formerly some of the species were regarded as medicinal, and several are said to be emetics. There are less than a dozen species in the United States, some of which in the wild state hybridize remarkably, and produce puzzling intermediate forms. The most common are coarse, weed-like, unattractive plants, found in old fields, along roadsides, and in waste places. The nettle-leaved verbena (*V. urticifolia*) is 4 to 6 ft. high, with coarsely toothed leaves, and long slender spikes of small white flowers; the blue verbena (*V. hastata*) is about as tall, with dense spikes of blue flowers; both are very common, and are often found together. The narrow-leaved, hoary, and bracted verbenas are mostly western and southern species; the European verbena (*V. officinalis*), a coarse inelegant species about 2 ft. high, is sparingly naturalized, especially in the southern states. The only one of our native verbenas sufficiently showy to be

Verbena. Garden Hybrids.

cultivated is *V. Aubletia*, which, with the absurd name of Rocky mountain verbena, and the incorrect botanical name *V. montana*, was a few years ago largely advertised as a new discovery; it is found southward and westward from Illinois and the Carolinas; the plant has the spreading habit and the deeply cleft leaves of the garden verbenas, with light purple flowers, and has been used in the various crossings which have produced these. —The garden verbenas are among the most popular of garden flowers, and have become so thoroughly mixed by numerous hybridizings and crossings that it is difficult to trace the now popular varieties to their origin. *V. chamædrifolia* was introduced into England in 1825 from Buenos Ayres, and *V. phlogifolia* into New York from Brazil in 1835; the first is the original scarlet, and the other the original rose-colored; about the same time seeds of *V. teucrioides*, with white flowers, were sent to this country from Brazil; and with these three our florists produced a series of hybrids, remarkable for the brilliancy and great variety of their flowers; they comprise every color and shade, from pure white to the deepest maroon, except a yellow and a positive blue, though a close approach to blue has been attained. European florists have also been engaged upon this plant, and the named varieties are almost innumerable, with yearly additions to the list; great improvement has also been made in the size and substance of the flower, form of truss, and habit of the plant; a distinct bright eye to each flower is essential, and in the striped varieties there must be no blending of colors. The verbenas, on account of their easy propagation, rapid growth, and brilliant, constant, and long-continued flowering, are the most popular flowers for producing color effects in that style of gardening known as bedding or massing, and are among the few that are really successful in our hot summers. The propagation from cuttings is rapid and easy, every joint making a plant; so readily does the stem throw out roots, that if a bouquet be left in water for a few days, the verbena stems will be found with minute rootlets. Where no particular colors are desired, the plants may be raised from seed, and if sown in the open ground in May will bloom in August.—The sweet-scented or lemon verbena belongs to a different genus of the same family; it is *Lippia* (formerly *Aloysia*) *citriodora*, a low, weak-branched shrub from Chili, with whorls of linear-lanceolate roughish leaves, and small, slender spikes of bluish white flowers; the leaves abound in glandular dots which contain a volatile oil, the fragrance of which is generally acceptable, and they are much used in summer bouquets. The plant is deciduous, and must have a season of rest; it is usually set in the open ground in spring, and housed in winter under the stage of a greenhouse or in a cellar. It can be trained in the form of a tree, with a distinct trunk and round head.

Hybrid Garden Verbenas.

VERBOECKHOVEN. I. Eugène Joseph, a Belgian painter, born at Warneton, West Flanders, June 8, 1799. He studied under his father, who had settled in Brussels as a sculptor, and learned painting alone. In 1821 he became known as an animal painter by his "Cattle Market at Geneva." In 1834 he received 10,000 francs from Baron James de Rothschild of Paris for his "Herd of Cattle in an Autumn Landscape." Some of his subsequent works, several of which are in the United States, brought still higher prices. Among them are "A Herd of Sheep overtaken by a Storm," "Horses attacked by Wolves," and "A Herd of Cattle in the Roman Campagna." He has published several volumes of etchings. **II. Charles Louis**, a Belgian painter, brother of the preceding, born in 1802. He was a pupil of his brother, and at first painted animals; but he afterward resided in Holland, devoting himself to marine painting. His works include "Fishing Boats drying their Sails," "Rising Tide," "Fishing Vessels in sight of Fort Lillo," and "View of the Port of Flushing."

VERCELLI (anc. *Vercellæ*), a city of Piedmont, Italy, in the province of Novara, on the W. bank of the Sesia, 40 m. N. E. of Turin; pop. in 1872, 27,349. It is the capital of a district of the same name, formerly a province, and is the seat of a bishop. The ramparts have been converted into boulevards. The Milan gate is of fine architecture. The cathedral, of the 16th century, is the most celebrated among many fine churches. It contains the tombs of St. Eusebius and St. Amadeus, and a library with manuscripts of great antiquity. The town has a palace, once the residence of the dukes of Savoy, a hospital with a picturesque cloister, a crypt-like Gothic chapel, a small museum with a botanic garden, a lyceum, a gymnasium, a technological school, an episcopal seminary, and a theatre. The main products of the environs are rice, hemp, flax, and silk, which is manufactured here.—The ancient Vercellæ, probably several miles from the present city, was the chief town of the Libici, in Cisalpine Gaul, and became a fortified Roman *municipium*. The Raudian fields, on which Marius defeated the Cimbri in 101 B. C., are supposed to have been near Vercellæ, though some place them near Verona. In the middle ages it was a lordship, and for some time a republic. In 1427 it was ceded by Milan to Savoy. Spain held it from 1638 to 1659, after which it remained in possession of Savoy till 1704, when the French, to whom it surrendered, razed the fortifications. In 1786 it was retaken.

VERCHÈRES, a S. W. county of Quebec, Canada, bounded N. W. by the St. Lawrence and S. E. by Richelieu river; area, 195 sq. m.; pop. in 1871, 12,717, all but 100 of French origin. It is traversed in the south by the Grand Trunk railway. Capital, Verchères.

VERD, Cape. See CAPE VERD.

VERD ANTIQUE. See MARBLE, vol. xi., pp. 147, 148.

VERDI, Giuseppe, an Italian composer, born at Busseto, in the duchy of Parma, Oct. 9, 1814. His father was an innkeeper, and his first instructions in music were given him by an obscure organist. In 1833 Antonio Barezzi offered to provide the means for his instruction at Milan. Failing to obtain an entrance into the conservatory, he was placed under the instruction of Lavigna, a member of the orchestra of La Scala. After studying operatic composition for six years, Verdi produced in 1839 his first work, *Oberto di San Bonifazio*, which met with moderate success. His next effort, a comic opera hastily written to order in 1841, called *Un giorno di regno*, was a positive failure. In 1842 he presented *Nabucco*, which instantly established his fame. In this work he developed those characteristics of brilliant melody and vivid musico-dramatic effects which have maintained his popularity undiminished to the present time. In 1843 he produced *I Lombardi*, a work of similar musical character to *Nabucco*, though somewhat more finished in detail. During the years 1844–'5 he wrote four grand operas, *Ernani*, *I due Foscari*, *Giovanna d'Arco*, and *Alzira*. For a time *Ernani* was the most popular of his works. Its qualities are extreme vigor and brilliancy of melody, without floridity, strongly marked melodramatic effects, and very resonant orchestration. It was first represented at Venice in March, 1844. At Venice he produced in 1846 his *Attila*, a feeble work, and at Florence in 1847 *Macbeth*, which, though exceedingly faulty, secured extraordinary public recognition. The composer was called before the audience more than 30 times at each of the first three performances, escorted to and from the theatre by triumphal processions, and offered the testimonial of a golden crown. This, however, was not exclusively an artistic laudation. Verdi was an ardent sympathizer with the liberal politicians of Italy, and the libretto of *Macbeth* was full of allusions to which the populace attached a political significance. In 1847 Verdi also visited London, and there produced *I masnadieri*, in the representation of which Jenny Lind took the principal part. In the same year his *Lombardi* was given, with French words and under the title *Jérusalem*, at the grand opera in Paris. In 1848 he wrote for Trieste *Il corsaro*, which failed, and for Rome *La battaglia di Legnano*, which was interdicted on account of the political bearing of the story. In 1849 he wrote for Naples *Luisa Miller;* in 1850, for Trieste, *Stiffelio;* in 1851, for Venice, *Rigoletto;* in 1853, for Rome, *Il trovatore;* and in the same year, for Venice, *La traviata*. In 1855 *Les vêpres siciliennes* was produced at the grand opera in Paris; and *Un ballo in maschera* was first represented in 1859 at Rome. His subsequent operas are *Aroldo* (a revision of his *Stiffelio*), *Simone Boccanegra*, *Una vendetta in domino*, *La forza del destino* (St. Petersburg, 1863), *Don Carlos* (1867), and *Aida* (Cairo, 1871). This last opera did much to elevate the reputation of its composer, being written with great elaboration. In 1874 he composed a requiem mass for the anniversary of Manzoni's death, which was performed under his direction in Paris, and in 1875 in London. He generally spends the winter at the Doria palace in Genoa. Verdi in 1859 was a member of the national assembly of Parma, and in 1861 of the Italian parliament; and in November, 1874, the king made him a senator.

VERDIGRIS. See COPPER, vol. v., p. 319.

VERDUN (anc. *Verodunum*), a town of Lorraine, France, in the department of Meuse, on the river Meuse, 130 m. E. N. E. of Paris; pop. in 1872, 10,738. The Meuse, which is navigable here, separates into several streams within the walls, which reunite on leaving the town. It has fine promenades, a cathedral and other churches, an episcopal palace and garden, an ecclesiastical seminary, a public library, and a theatre. The trade is in wine, liqueurs, confectionery, oil, grain, timber, and cattle; and linen and woollen fabrics, leather, &c., are manufactured. It has a strong citadel designed by Vauban, separated from the town by an esplanade, and the enceinte consists of ten fronts.—Verdun was a town of some importance under the Romans. Charlemagne's Frankish empire was divided into three kingdoms by the treaty of Verdun in August, 843. The Verdunois territory belonged to the dukes of Lorraine, who governed it through local counts. Baldwin, the brother of Godfrey of Bouillon, sold it to the bishop of Verdun, who gave it in fief for some time as a viscounty to the count of Monçon and Bar. Verdun early became a free imperial city of the German empire; but the bishops claimed absolute authority, and the numerous conflicts resulted in 1552 in French domination, which the Westphalian treaty sanctioned. The royalists surrendered the town to the Prussians, Sept. 2, 1792, in consequence of which the commander of the citadel (Beauregard) shot himself, and subsequently many of the former were executed by the republican authorities. In the war of 1870 Verdun surrendered after a siege of about a month, Nov. 8. Many officers and much artillery and war material fell into the hands of the Germans. Verdun was substituted for Belfort as a pledge to the Germans until the final payment of the war indemnity in 1873.

VERE. I. Sir Aubrey de, an Irish poet, born Aug. 20, 1788, died July 5, 1846. He succeeded to the baronetcy and family estates, in Limerick and Tipperary counties, in 1818. He published two dramatic poems, "Julian the Apostate" (1822) and "The Duke of Mercia" (1823), and "A Song of Faith, and other Poems" (1842). **II. Aubrey Thomas de,** an Irish author, third son of the preceding, born at Curra Chase, county Limerick, Jan. 10, 1814. He was educated at Trinity college, Dublin. He has published "The Waldenses, and other Poems" (1842); "The Search after Proserpine, and other Poems" (1843); "English Misrule and Irish Misdeeds" (1848); "Picturesque Sketches of Greece and Turkey" (2 vols., 1850); "Poems, Miscellaneous and Sacred" (1856); "May Carols" (1857); "The Sisters, and other Poems" (1861); "The Infant Bridal, and other Poems" (1864); "The Church Settlement of Ireland" (1866); "Irish Odes, and other Poems" (1869); "The Legends of St. Patrick" (1872); and "Alexander the Great, a Dramatic Poem" (1874).

VERGENNES, a city of Addison co., Vermont, on Otter creek, 7 m. from its mouth in Lake Champlain, and on the Rutland division of the Central Vermont railroad, 21 m. S. of Burlington; pop. in 1870, 1,570. Its area is only 480 by 400 rods, not quite 2 sq. m. The falls of Otter creek afford a large amount of hydraulic power, which is partially improved. The manufactures include curtain rolls, doors, sash, and blinds, furniture, guns, hubs, spokes, &c., pumps, leather, and nails. There are three churches, a graded school, a weekly newspaper, and a national bank. The state reform school for boys is situated here. The harbor is an excellent one, affording a sufficient depth of water for the largest vessels. In the war of 1812 Com. McDonough's fleet was fitted out here. The city was settled in 1766, and incorporated in 1788.

VERGENNES, Charles Gravier, count de, a French statesman, born in Dijon, Dec. 28, 1717, died in Versailles, Feb. 13, 1787. He early accompanied his relative M. de Chavigny on diplomatic missions, and was minister at Treves from 1750 to 1755, and afterward at Constantinople till 1768, when the prime minister Choiseul, dissatisfied with his failure to instigate a Turco-Russian war, recalled him on the ground of his having married a Greek woman of low degree; but after Choiseul's removal he was restored to the service in 1771 as minister to Sweden, and in 1774 he became minister of foreign affairs on the recommendation of Count de Maurepas. He was very friendly to the American patriots, and the treaties of commerce (Dec. 8, 1777) and of alliance (Feb. 6, 1778) with the American colonies, as well as the preliminary (Nov. 30, 1782) and the final treaty of peace with Great Britain (Sept. 3, 1783), were all concluded under his administration. In the mean time he had brought about the treaty of Teschen (May 13, 1779), ending the war of the Bavarian succession. At home, he contributed to the downfall of Necker, and in 1783 became president of the royal council of finance, and later of the new committee of finance; and in the same year he promoted the appointment of Calonne as comptroller general of that department. Louis XVI. lost in him one of his most judicious advisers at the most critical period of his reign. He wrote various memoirs, but the *Mémoire historique et politique sur la Louisiane* (Paris, 1802), attributed to him, is of doubtful authorship.

VERGIL, Polydore, an English historian, born in Urbino, Italy, about 1470, died in his native country in 1555. Being in holy orders, he was sent to England in 1501 by Pope Alexander VI. as collector of the tax called Peter's pence, which office he was the last to hold. He was made rector of Church-Langton in Leicestershire, archdeacon of Wells (1507), and a prebendary successively in the cathedrals of Hereford and Lincoln, and in St. Paul's, London (1513). When he had been nearly 50 years in England, he returned to Italy with a present of 300 crowns, and leave to hold his archdeaconry of Wells and his prebend at Hereford during life. His principal work is his *Historia Anglica* (fol., 1534), a history of England from the earliest time to the end of the reign of Henry VII. Two portions of an old English version of it have been printed by the Camden society (4to, 1844–'6). He also published a collection of *Adagia* or proverbs (1498); a work *De Rerum Inventoribus* (1499; translation by John Langley, with W. A. Hammond's "Account of the Author and his Works," Agathynian club, New York, 1868); three books of dialogues against divination, entitled *De Prodigiis* (Basel, 1531); and treatises *De Patientia*, *De Vita Perfecta*, and *De Mendaciis*. Some passages in his *De Rerum Inventoribus* were placed on the Index at Rome.

VERGNIAUD, Pierre Victurnien, a French revolutionist, born in Limoges, May 31, 1759, executed in Paris, Oct. 31, 1793. He was admitted to the bar in Bordeaux in 1781, where he gained great distinction. He warmly supported the revolution of 1789, and in 1791 was elected to the legislative assembly, of which he became vice president (Oct. 16) and president (Oct. 31). He advocated severe measures against the emigrants, acted generally in opposition to the monarchy, promoted the proclamation of the republic in 1792, and was elected to the national convention. On the trial of the king he supported the proposition to allow an appeal

This type indicates a population of 2,000 or over.

to the people; but this being defeated, he voted for his execution without delay, and as president pronounced the sentence. From this time until the downfall and arrest of the Girondists (May 31 and June 2, 1793), of whom he was the most eloquent leader, he was engaged in a continual struggle against Robespierre and the ultra-revolutionists (*montagnards*). He appeared with his friends before the revolutionary tribunal, Oct. 24, and made a bold and eloquent defence, but with his colleagues was sentenced to death, Oct. 30. His most important speeches are contained in *Choix de rapports, opinions et discours* (Paris, 1818–'25).—See *Histoire parlementaire et vie intime de Vergniaud*, by Touchard-Lafosse (1848).

VERIA, or **Verria** (anc. *Berœa*), a town of European Turkey, in Macedonia, on a tributary of the Vistritza (anc. *Haliacmon*), 38 m. W. S. W. of Salonica; pop. about 10,000. It is one of the most agreeable towns in Macedonia, and contains considerable remains of antiquity. The vicinity abounds in fruits, and cotton weaving, dyeing, and carpet manufactories are carried on.—St. Paul and Silas withdrew to ancient Berœa from Thessalonica. The apostle preached the gospel here, and Sopater, a native of the place, accompanied him to Asia.

VERMICELLI. See MACARONI.

VERMIGLI, Pietro Martire, commonly called PETER MARTYR, an Italian reformer, born in Florence, Sept. 8, 1500, died in Zürich, Nov. 12, 1562. At an early age he entered the order of regular canons of St. Augustine, and by his learning and eloquence became famous throughout Italy. Intercourse with a Protestant convert at Naples, and the writings of Bucer, Zwingli, and Melanchthon, induced him to adopt their doctrines. His opinions becoming known while he was prior at Lucca, he was in 1542 compelled to fly to Switzerland, and was soon after made professor of divinity at Strasburg. In 1547 he went to England on the invitation of Cranmer, and was appointed by Edward VI. lecturer upon the Holy Scriptures at Oxford. On the accession of Queen Mary he resumed his chair at Strasburg, and also lectured on Aristotelian philosophy till 1556, when he became professor of theology at Zürich. He was present at the celebrated conference of Poissy in 1561. Peter Martyr was one of the most learned men of the Reformed church, and was the author of many works, among which were epistles to "his Brethren of the Protestant Church of Lucca," to the Protestant churches in Poland, to Calvin, Bullinger, Beza, Melanchthon, Queen Elizabeth, and others, commentaries on various parts of the Scriptures, and works on Christian ethics. Several of his works in Latin and English were printed in the 16th century in England, the last in 1583, dedicated to Queen Elizabeth, as "The Commonplaces of the most famous and renowned Divine Doctor Peter Martyr, divided into four principal Parts by Anthony Marten."

VERMILION. See CINNABAR.

VERMILION, or Vermillion. I. A S. W. parish of Louisiana, bordering on the gulf of Mexico, and intersected by Vermilion river; area, about 1,400 sq. m.; pop. in 1870, 4,528, of whom 1,047 were colored; in 1875, 6,697, of whom 1,551 were colored. The surface is level prairie, and in many places marshy. Vermilion river, flowing into Vermilion bay in this parish, is navigable for steamboats. The chief productions in 1870 were 111,995 bushels of Indian corn, 22,087 of sweet potatoes, 969 bales of cotton, 259 hogsheads of sugar, 10,165 gallons of molasses, and 421,501 lbs. of rice. There were 2,056 horses, 3,183 milch cows, 12,029 other cattle, 1,502 sheep, and 3,595 swine; 4 manufactories of carriages and wagons, and 8 of molasses and sugar. Capital, Abbeville. **II.** A W. county of Indiana, bordering on Illinois, bounded E. by the Wabash and intersected by Vermilion river; area, 290 sq. m.; pop. in 1870, 10,840. The surface is generally level, and the soil highly fertile, a large portion of the county consisting of beautiful prairie land. Iron ore and bituminous coal abound. The Evansville, Terre Haute, and Chicago railroad traverses it. The chief productions in 1870 were 261,246 bushels of wheat, 598,322 of Indian corn, 54,257 of oats, 33,167 of potatoes, 145,253 lbs. of butter, 44,595 of wool, and 9,659 tons of hay. There were 3,551 horses, 2,278 milch cows, 4,902 other cattle, 13,552 sheep, and 14,047 swine; 1 pork-packing establishment, 5 flour mills, 3 saw mills, and 2 woollen mills. Capital, Newport. **III.** An E. county of Illinois, bordering on Indiana, drained by Vermilion and Little Vermilion rivers and their affluents, and traversed by several railroads; area, about 1,200 sq. m.; pop. in 1870, 30,388. The surface is level, and the soil very fertile. Bituminous coal is found along the banks of Vermilion river. The chief productions in 1870 were 294,364 bushels of wheat, 52,479 of rye, 2,818,027 of Indian corn, 436,051 of oats, 172,558 of potatoes, 632,624 lbs. of butter, 278,554 of wool, and 52,553 tons of hay. There were 15,282 horses, 1,122 mules and asses, 9,681 milch cows, 24,078 other cattle, 67,890 sheep, and 50,177 swine; 17 manufactories of carriages and wagons, 5 of furniture, 1 of iron castings, 1 of machinery, 9 flour mills, and 2 woollen mills. Capital, Danville.

VERMONT, so called from its principal range of mountains (Fr. *verd* or *vert*, green, and *mont*, mountain), one of the New England states of the American Union, and the first admitted under the federal constitution. It lies between lat. 42° 44′ and 45° 3′ N., and lon. 71° 38′ and 73° 25′ W., and is bounded N. by Canada, E. by New Hampshire, S. by Massachusetts, and W. by New York and Lake Champlain, of which nearly two thirds lies within the state; area, 10,212 sq. m. It is divided into 14 counties, viz.: Addison, Bennington, Caledonia, Chittenden, Essex, Franklin, Grand Isle, Lamoille, Orange, Orleans, Rutland, Washington, Windham, and Windsor. There are only two incorporated cities in the state: Burlington, which in 1870 had 14,387 inhabitants, and Vergennes, with a population of 1,570. The capital, Montpelier, had in 1870 a population of 3,023. There are 241 towns, the most important of which are Bennington, Brandon, Brattleboro, Castleton, Colchester, Fairhaven, Middlebury, Northfield, Rockingham, Rutland, St. Albans, St. Johnsbury, Springfield, Waterbury, Windsor, and Woodstock. The population of the state, according to the decennial censuses, has been as follows:

State Seal of Vermont.

YEARS.	White.	Colored.	Total.	Rank.
1790	85,154	271	85,425	12
1800	153,908	557	154,465	13
1810	217,145	750	217,895	15
1820	235,063	903	235,966	16
1830	279,771	881	280,652	17
1840	291,218	730	291,948	21
1850	313,402	718	314,120	23
1860	314,369	709	315,098	28
1870	329,613	924	330,551	30

Included in the total of 1870 are 23 Indians, and 20 in that of 1860. Of the total population in 1870, 165,721 were males and 164,830 females; 283,396 were native and 47,155 foreign born. Of those of native birth, 243,272 were born in the state, 9,202 in Massachusetts, 13,540 in New Hampshire, and 11,297 in New York. Of the foreigners, 28,544 were born in British America, 1,946 in England, 14,080 in Ireland, and 1,240 in Scotland. The density of population was 32·37 persons to a square mile. There were 70,462 families, with an average of 4·69 persons to each, and 66,145 dwellings, with an average of 5 to each. Between 1860 and 1870 there was an increase of 4·90 per cent. in the total population. There were 89,831 persons from 5 to 18 years of age, 62,459 males from 18 to 45, and 74,867 male citizens 21 years old and upward. There were 15,185 persons 10 years of age and over unable to read, and 17,706 who could not write, of whom 13,804 were foreign born. The number of illiterates 21 years old and over was 13,394. The number of paupers supported during the year ending June 1, 1870, was 2,008, at a cost of $178,628. Of the number (1,785) receiving support at that date, 523 were foreigners. The number of persons convicted of crime during the year was 139, and there were 193 in prison at the close of the year. The state contained 189 blind, 148 deaf and dumb, 721 insane, and 325 idiotic. Of the total population (258,751) 10 years of age and over, there were engaged in all occupations 108,763; in agriculture 57,983, of whom 23,692 were laborers and 34,144 farmers; in professional and personal services, 21,032, including 591 clergymen, 9,588 domestic servants, 6,426 laborers, 72 lawyers, 569 physicians and surgeons, and 1,895 teachers; in trade and transportation, 7,132; and in manufactures and mechanical and mining industries, 22,616. The total number of deaths was 3,545, or 1·07 per cent. of the population. There were 715 deaths from consumption, there being 5 deaths from all causes to one from that disease; from pneumonia, 225 deaths, or 15·8 deaths from all causes to one from that disease; cholera infantum, 105; diphtheria and scarlet fever, 115; enteric fever, 221; dysentery, 103.—The surface of the state is greatly diversified by hills and valleys, gentle acclivities, elevated plateaus, and mountains of considerable height. The Green mountain range extends through the state from its S. line in a northerly direction to the vicinity of lat. 44°, where it divides into two chains, one of which continues N. by E. to the Canada line, while the other turning N. E. extends to the New Hampshire line, where it joins that of Canada. (See GREEN MOUNTAINS.) These mountains are not generally granitic, and their rounded grassy summits offer a striking contrast to the lofty, bare, and jagged peaks of the White mountains. There are considerable quantities of cultivated land at an elevation of 2,000 to 2,500 ft. above tide water.—The E. part of the state is drained by the affluents of the Connecticut; the most important of these are the Passumpsic, Wells, White, Black, West, and Deerfield rivers, the last named lying chiefly in Massachusetts. The Connecticut itself, forming the entire boundary line between Vermont and New Hampshire, belongs wholly to the latter state. The streams on the W. side of the state discharge their waters into Lake Champlain; the most important are Otter creek, Winooski or Onion river, a beautiful stream with abundant water power, and the Lamoille and Missisquoi rivers. Two or three small streams fall into Lake Memphremagog on the Canada border, the S. part of which is in the state. There are numerous small lakes, the principal of which are Lakes Willoughby, Maidstone, Seymour, Dunmore, Austin, and Bombazine. Long pond, or as it is now commonly called "Runaway pond," was formerly situated between two hills on the height of land dividing the watershed in the towns of Glover and Greensborough, and was one of the sources of the Lamoille river. In June, 1810, an attempt was made to open an outlet from it to Barton river on the north, when all the water of the pond, which was 1½ m. long and ½ m. wide, tore its way through the quicksand, which was only separated by a thin stratum of clay from the pond, and advanced in a wall from 60 to 70 ft. high and 20 rods wide, carrying everything before it, reaching Lake Memphremagog, 27 m. distant, in about six hours. There are several islands in Lake Champlain and one or two in Lake Memphremagog belonging to the state; the largest are North and South Hero and Isle la Motte in Lake Champlain, which with the peninsula of Alburg constitute Grand Isle co. The only considerable harbor is that of Burlington, on Lake Champlain.—The geological formations of Vermont consist chiefly of the lower groups of the geological column comprised in the azoic and Silurian divisions. The Devonian formation is represented by a band of limestone about a mile wide and 20 or 30 m. long on the E. side of the Green mountains. The drift formation overspreads the whole state, and alluvial deposits of limited extent are met with along the banks of the rivers. The lower formations are all of uncertain age, owing to the metamorphic character of the rocks, their doubtful stratigraphical relations, and their dearth of fossils. Their determination has been an interesting subject of investigation. The Green mountain range is composed chiefly of gneiss, which may be the oldest rock in Vermont, or may prove to be of Silurian or Devonian age, or both in a metamorphic condition. Should this prove to be anticlinal, the group will then pass on each side under rocks of later age; but if its structure is synclinal, it then overlies the rocks on either side; so far it has been found impracticable to determine this question. Along the W. base of the Green mountains extends a great belt of quartz rock, which in the opinion of the surveyors rests upon the gneiss, and which has been supposed to be the equivalent of the Potsdam sandstone, though now regarded by the Vermont surveyors as of the age of the Medina sandstone of the Clinton group of New York. Apparently overlying this is a great bed of crystalline limestone 2,000 ft. thick called the Eolian limestone, from Mt. Eolus in the S. W. part of the state. This has been generally referred to the lower Silurian group, but its true position in the geological series is very doubtful. The rock constitutes the principal portion of several ranges of mountains in the S. part of the state. Along Lake Champlain the rocks are lower Silurian and primordial, slates found in the town of Georgia being referred to the latter system on the evidence of trilobites discovered in them. The Laurentian group is represented in a small exposure near Whitehall at the S. extremity of Lake Champlain.—Various mineral productions of value are found in connection with the ancient formations of this state. The talcose slates and quartz rocks, as throughout the whole range of the Appalachian chain, present numerous deposits of hematite iron ore. The same formation has also furnished productive mines of manganese at Chittenden; and at Plymouth and several other places it has produced gold. Lead ores, more or less argentiferous, have been found at several localities along this range, but have not proved profitable. At Vershire and Corinth, Orange co., is a large vein of pyritous copper ore. In the serpentine rocks about Troy, in the extreme north, chromic iron has been met with in considerable quantity. Excellent clay for white stone ware has been worked for the pottery at Bennington, and beds of soapstone are found in many towns along the central N. and S. line of the state. Vermont is rich in marble and slate. Marble was first quarried at Rutland in 1844, and the quarries there now supply about half of the production of Vermont. The marbles obtained are the white statuary and the variegated, mottled, and blue. The proportion of white is larger than in any other part of the state; it is not inferior to the best Italian. The Sutherland Falls and East Dorset quarries produce marble resembling the veined Italian. The Swanton and Isle la Motte marble when polished is jet black. The Lake Champlain quarries produce marble resembling brocatella. Winooski yields fine Siena and other grades of pale red and white. There are valuable slate quarries in Rutland, Washington, and Windham counties. The first quarry was opened at Fairhaven, Rutland co., in 1845. For many years the production was inconsiderable; but this industry has now become important in consequence of the increased demand for roofing slates, floors, tiles, &c. In 1875 the production was valued at $370,000, being chiefly from the Fairhaven quarries.—The state abounds in beautiful waterfalls and other natural curiosities. The most remarkable, besides Bellows falls in the Connecticut, adjoining a village of the same name in the town of Rockingham, but belonging to New Hampshire, are the "Great falls" on the Lamoille in Milton; the McConnel's falls, and the natural bridge a little below them, in Johnson; the "Great falls" on the Clyde in Charleston, where there is a descent of 100 ft. in 40 rods; the numerous falls on the Winooski, with its natural bridge and caverns in Duxbury; the magnificent fall of 70 ft. in the Missisquoi at Troy, and the gentler one at Highgate; the falls in the Passumpsic at Lyndon; the falls in the Black river at Springfield; and the caves at Dorset and Plymouth.—The climate of Vermont is severe, and the winters are cold; but there are not many sudden changes, and the state is remarkably healthful. Observations at Lunenburg (lat. 44° 28′, lon. 71° 41′, elevation 1,210 ft.) show the following average means for 25 years: January, 16·54°; February, 17·38°; March, 26°; April, 37·86°; May, 52·18°; June, 65·05°; July, 68·39°; August, 65·82°; September, 56·31°; October, 44·51°; November, 31·38°; December, 19·14°; year, 41·72°; annual rainfall and melted snow, 41·11 inches; snow, 83·1 inches.—The soil is generally a rich loam, most fertile where the underlying rock is limestone. The forest trees are hemlock, fir, and spruce on the mountains, oak, beech, sugar maple, pine, hickory, elm, butternut, basswood, and birch on the lower lands, and cedar in the swamps. The mountains are generally covered with timber or afford good pasturage, and the proportion of unimprovable land is smaller than in some less mountainous states. As a large proportion of the land is better adapted to grazing than to tillage, much attention has been given to the raising of live stock, and the horses, cattle, sheep, and swine of Vermont are of excellent quality. The wild animals are the panther, wild cat, lynx, raccoon, wolf, fox, moose (found only in the extreme north of the state, and scarce even there), elk, deer, black bear, and rabbits and squirrels of several species. The birds are those of New England generally, but the northern aquatic birds appear in large numbers and early in the season on Lake Champlain. The lake yields large quantities and numerous varieties of fish. The muscalonge is the largest, and the lake white fish, salmon trout, pickerel, roach, perch, and other smaller fish are abundant. The proteus, an uncommon reptile in northern waters, is found there in considerable numbers. The rattlesnake, the black snake, two or three species of adder, and the harmless species of serpents are not infrequent.—In 1870 the number of acres of improved land in farms was 3,073,257; woodland, 1,386,934; other unimproved land, 68,613; percentage of improved land in farms to total land in farms, 32·1. The total number of farms was 33,827, the average size being 134 acres. There were 1,719 farms containing from 3 to 10 acres, 1,998 from 10 to 20, 6,210 from 20 to 50, 10,761 from 50 to 100, 12,934 from 100 to 500, 102 from 500 to 1,000, and 15 of over 1,000 acres. The cash value of farms was $139,367,075; of farming implements and machinery, $5,250,279; total estimated value of all farm productions, including betterments and additions to stock, $34,647,027. According to the United States department of agriculture, the chief productions in 1873 were as follows:

CROPS.	Quantity produced.	No. of acres in each crop.	Average yield per acre.	Total value.
Indian corn, bush.	1,748,000	56,387	31	$1,485,800
Wheat	399,000	24,937	16	666,330
Rye	60,000	8,727	16·1	57,000
Oats	3,579,000	109,785	32·6	1,753,710
Barley	97,000	4,075	23·8	83,420
Buckwheat	365,000	17,807	20·5	262,800
Potatoes	5,088,000	36,343	140	2,238,720
Tobacco, lbs	350,000	275	1,272	70,000
Hay, tons	893,200	812,000	1·1	11,951,016
Total	....	1,065,336	.....	$18,568,796

The number and value of farm animals were as follows:

ANIMALS.	Number.	Average price.	Total value.
Horses	71,000	$85 20	$6,049,200
Oxen and other cattle	128,000	32 88	4,208,640
Milch cows	195,700	35 50	6,947,350
Sheep	543,600	3 59	1,951,524
Hogs	53,500	9 59	513,065

In 1870 the production of hay was 1,020,669 tons; wool, 3,102,137 lbs.; potatoes, 5,157,524 bushels; butter, 17,844,396 lbs.; cheese (on farms), 4,830,700 lbs.; hops, 527,927 lbs.; maple sugar, 8,894,302 lbs.; maple molasses, 12,023 gallons; honey, 142,932 lbs. In the production of these articles Vermont holds a high rank among the states of the Union.—Practical measures have been taken by the state for the promotion of pisciculture. This industry is under the supervision of two commissioners, who have deposited large numbers of shad, salmon, and other varieties of fish in the waters of the state. There are in the state 145 natural ponds of 50 acres and upward, covering in the aggregate 77,315 acres. These are now inhabited by varieties of fish almost worthless, such as pickerel, bream (sunfish), suckers, and dace; it is proposed to stock them with trout, salmon, whitefish, &c. The total number of manufacturing establishments in 1870 was 3,270, having 186 steam engines of 6,425 horse power and 1,984 water wheels of 44,897 horse power, and employing 18,686 hands, of whom 16,301 were males above 16 years of age, 1,872 females above 15, and 513 youth. The capital invested amounted to $20,329,637; wages paid during the year, $6,264,581; value of materials used, $17,007,769; of products, $32,184,606. The leading establishments were as follows:

INDUSTRIES.	No. of establishments.	Hands employed.	Capital.	Value of products.
Agricultural implements	45	372	$518,150	$523,669
Blacksmithing	385	759	273,665	566,189
Boots and shoes	212	751	281,679	838,325
Carriages and wagons	162	616	465,670	620,207
Cars, freight and passenger	2	250	175,000	452,470
Cheese	28	92	107,700	445,323
Cotton goods, not specified	8	451	670,000	546,510
Flouring and grist-mill products	220	500	1,231,050	3,895,058
Furniture, not specified	47	413	439,175	540,521
" chairs	33	323	262,000	355,085
Leather, tanned	86	321	620,743	1,249,942
" curried	64	137	156,390	762,571
" dressed skins	5	17	60,000	40,400
Lumber, planed	19	1,342	2,007,600	2,544,603
" sawed	637	2,782	2,872,451	3,525,122
Machinery	48	678	1,054,058	1,122,567
Musical instruments	2	204	302,000	348,999
Sash, doors, and blinds	43	331	286,900	518,125
Scales and balances	2	363	280,000	1,629,000
Tin, copper, and sheet-iron ware	97	339	358,150	505,005
Woollen goods	43	1,892	2,297,500	3,550,962

Besides the above, there were 54 mining and quarrying establishments, employing 906 hands;

capital invested, $2,494,700; value of products, $905,410. The production of copper in 1870 was valued at $358,845, of marble at $130,800, and of slate at $361,765. The production of marble in 1875 was as follows:

CHARACTER OF MARBLE AND WHERE PRODUCED.	Feet.	Cash value.
Rutland statuary, white, variegated, mottled, and blue	2,000,000	$1,000,000
Sutherland Falls and East Dorset, imitation Italian	850,000	300,000
Dorset, less valuable	1,000,000	300,000
Brandon, Isle la Motte, Swanton, and other marble	550,000	275,000
Total	4,400,000	$1,875,000

A considerable foreign commerce is carried on with Canada through Burlington, which is the port of entry of the United States customs district of Vermont. The value of imports for the year ending June 30, 1875, was $2,631,748; of exports, $2,496,830. There were entered in the foreign trade 728 vessels of 97,778 tons; cleared, 690 vessels of 95,120 tons. The total number of vessels registered, enrolled, and licensed was 23, of 4,631 tons.—In 1850 there were but two railroads in Vermont: the Champlain and Connecticut River (now the Rutland), extending from Bellows Falls to Burlington by way of Rutland, and the Vermont Central, from the Connecticut river, in the town of Windsor, to Burlington. The former was opened for travel in December, 1849, and the latter in January, 1850. The total extent of railroads in the state amounted to 554 m. in 1860, 614 m. in 1870, and 765 m. in 1876. About $35,000,000 has been expended in the construction of railroads in the state, besides the equipment of the roads and other personal property, which make the aggregate about $50,000,000. Nearly the whole of this amount is exempt from taxation. The railroads lying wholly or partly in the state in 1876, with their lengths and termini, were as follows:

NAME OF CORPORATION.	TERMINI.		LENGTH.	
	FROM	TO	Total.	In Vermont.
Addison	Leicester	Ticonderoga, N. Y	16	16
Atlantic and St. Lawrence	Portland, Me.	Island Pond	149	15
Connecticut and Passumpsic and Massawippi	White River Junction	Sherbrooke, Canada	145	110
Harlem Extension	Rutland	Chatham Four Corners, N. Y.	113	63
Missisquoi	St. Albans	Richford	30	30
Montpelier and Wells River	Montpelier	Wells River	38	38
Montpelier and White River	Montpelier	Barre	6	6
Portland and Ogdensburg (Vermont division)	Lunenburg	Johnson	77	77*
Rensselaer and Saratoga	Troy, N. Y	Rutland	95	26
Branch	Eagle Bridge, N. Y	Castleton	61	17
Rutland	Bellows Falls	Burlington	120	120
Missisquoi and Clyde River	Newport	West Farnham, Canada	65	22
Vermont and Canada	Essex Junction	Rouse's Point, N. Y	59	59†
Vermont and Massachusetts	Miller's Falls, Mass.	Brattleboro	21	10
Vermont Central	Windsor	Burlington	117	117
Vermont Valley	Bellows Falls	Brattleboro	24	24
Woodstock	White River Junction	Woodstock	15	15

The Addison, Harlem Extension, Missisquoi, Rutland, Vermont and Canada, Vermont and Massachusetts, Vermont Central, and Vermont Valley are all operated by the Central Vermont railroad company.—On Nov. 1, 1875, there were in the state 46 national banks, with a paid-in capital of $8,945,390; circulation issued, $13,702,250; outstanding, $7,178,581; 20 savings banks, with 27,677 depositors and deposits amounting to $7,590,599; and 6 fire and 3 life insurance companies incorporated by Vermont.—The legislative power is vested in a general assembly, consisting of a senate of 30 members and a house of 241 representatives, one from each town. The sessions of the general assembly are biennial, beginning on the first Wednesday of October in even years. Each of the 14 counties is entitled to one senator at least, and the remainder of the senators are apportioned among the several counties according to the population as returned by the latest federal census. Senators and representatives are chosen for two years, and receive $3 a day each during the session. The chief executive officers are the governor (annual salary, $1,000), lieutenant governor, who acts as president of the senate and receives $6 a day during the session, secretary of state, treasurer, auditor, and superintendent of education, who each receive $1,500 a year. The governor's power of appointment is very limited, usually extending merely to his secretary and military staff; but he may fill a vacancy until the office is provided for in the manner prescribed by law. He is empowered to nominate, subject to approval by the senate, six members of the state board of agriculture, manufactures, and mining. The governor, lieutenant governor, and treasurer are elected for two years by the freemen of the state; the secretary of state, auditor, and superintendent of education are chosen by the legislature. The other state officers comprise an inspector of finance, savings banks, and trust companies, a railroad commissioner, a commissioner of the insane, two commissioners of insurance and two of fisheries, a superintendent of the state prison, a superintendent of the reform

* To be completed to Swanton, 118 m.
† Including Swanton branch to Canada line, 10 m.

school, a state librarian, a geologist and curator of the state cabinet, an adjutant and inspector general, a quartermaster general, a judge advocate general, and a surgeon general. The supreme court comprises a chief and six associate justices, each of whom receives an annual salary of $2,500. A general session of the court is held annually at Montpelier, and annual sessions are held in each county. County courts are held by a judge of the supreme court with the two assistant county judges. United States courts are held in Burlington, Windsor, and Rutland. Judges of the supreme court are chosen for two years by joint ballot of the legislature. County and probate judges, sheriffs, state attorneys, and high bailiffs are elected for two years by the freemen of the counties, and justices of the peace by the freemen of the towns for the same term. The general election for state officers and members of the legislature is held biennially, on the first Tuesday of September in even years. Every man of the age of 21 years, who is a natural-born or naturalized citizen of the United States and has resided for one year in the state, and is of quiet and peaceable behavior, becomes entitled to the privileges of a freeman upon oath or affirmation that in voting he will, according to his judgment, aim to promote the good of the state. Town meetings are held in March of each year. For the rights of married women concerning their property and earnings, see HUSBAND AND WIFE, vol. ix., p. 87. For the grounds of divorce, see DIVORCE, vol. vi., p. 160. Vermont is represented in congress by two senators and three representatives, and has therefore five votes in the electoral college. The total liabilities of the state on Aug. 1, 1875, amounted to $328,584, including the funded debt of $167,500, of which $102,000 will fall due on Dec. 1, 1876, and $65,500 on Dec. 1, 1878; the agricultural college fund of $135,500; due to towns from the United States surplus fund, $11,520; soldiers' accounts, $12,178; outstanding checks, $1,886. The resources were $324,940, including $320,377 cash in treasury and in banks, and $4,563 taxes due from 11 towns. Exclusive of the sinking fund account, the receipts into the treasury during the year ending July 31, 1875, were $500,656, and the disbursements $510,230. The valuation of real estate in 1875 was $81,106,760, which is about 40 per cent. of the real value, estimated at $200,000,000. The grand list of the state is 1 per cent. of the valuation. In 1872 the state tax was 40 per cent. on the grand list of $1,171,619; in 1873 it was 35 per cent. on the grand list of $1,175,476. Adding the tax on gores and unorganized towns, and deducting for abatements and collection fees, the amount of the tax was $448,408 in 1872, and $393,660 in 1873. According to the federal census of 1870, the assessed value of property was $102,548,528, including real estate returned at $80,993,100 and personal at $21,555,428. The true valuation of real and personal estate was returned at $235,349,553. —The state asylum for the insane, opened in 1836, is at Brattleboro, on a beautiful site of 20 acres. It has accommodations for from 450 to 500 patients. During the two years ending Aug. 1, 1874, the total number of inmates was 699, of whom 245 were state beneficiaries; average number, 473; discharged, 172, of whom 48 were recovered, 87 improved, and 37 stationary; died, 37; remaining, Aug. 1, 1874, 471, of whom 163 were state beneficiaries. The expenses of the institution during the two years amounted to $213,929, of which $56,214 was for building account, and $14,210 for repairs and improvements. The institution is subject to the inspection of the state commissioner of the insane. The state prison at Windsor had during the two years ending Aug. 1, 1874, 151 convicts, of whom 85 were in confinement at the end of that period. The income of the prisons for the two years, chiefly from the labor of convicts, was $28,331; the expenses were $25,081. The convicts are employed in the prison in making shoes; their labor is let to contractors at 70 cents a day for each prisoner. The state reform school was opened at Waterbury in 1866, and removed to Vergennes in 1875. Boys under 16 years of age are committed by courts, parents, and guardians; they receive instruction, and are employed in industrial occupations. The whole number of inmates from the opening to Aug. 1, 1874, was 416, of whom 145 were remaining at that date. The current expenses of the institution were $20,088 in 1872, and $21,843 in 1873. The average annual expense of each boy to the state, after deducting earnings, was $85 27. Vermont has no institution for the deaf and dumb, or the blind; but an annual appropriation not exceeding $5,000 is authorized for the instruction of the deaf and dumb in institutions of other states, and not exceeding $4,000 for the benefit of the blind.—In 1874 the board of education was abolished and the supervision of common schools vested in a state superintendent of education, who is elected biennially by the legislature and receives an annual salary of $1,500 and travelling expenses. Among other things, he is required, upon written application of 25 teachers in any county (except Grand Isle and Essex counties, in which the number may be 15), to hold a teachers' institute once a year. In each town a superintendent is elected by the people annually. It is his duty to hold two annual examinations of teachers, and to grant certificates. Principals of graded and union schools are not required to obtain such certificates. The town superintendent is required to visit at least once a year all the common schools of the town, and to make an annual report to the state superintendent, who reports biennially to the legislature. Each organized town must maintain one or more schools; when necessary, the town must be divided into school districts unless it has abolished the district system. The school officers of each district are a moderator to preside in the meetings, clerk, collector of taxes, treasurer, one or three auditors, and a prudential committee consisting of one or three voters in such district; they are elected by the people. By act of 1870 towns are authorized to abolish the district system, and to vest the management of the public schools in six directors elected by the people for three years, one third each year. The law of 1872 authorizes towns that have abolished the district system to return to it. Vermont has no school fund, the schools being supported by direct taxation levied by the towns. Under the act of 1867 every child between 8 and 14 years of age is required to attend a public school at least three months in the year, unless he has been otherwise instructed for a like period, or has acquired the branches of learning taught in the public schools. No child of this age who has resided in the state one year shall be employed in any mill or factory unless he has attended a public school three months within the year next preceding. A penalty of not less than $10 nor more than $20 is imposed upon every parent, guardian, or employer violating the provisions of this act. The condition of public education in 1873 and 1874 is shown by the following statistics:

PARTICULARS.	1873.	1874.
Number of organized school districts.	2,168	2,224
" of fractional districts........	487	530
" of common schools..........	2,637	2,782
" of academic and private schools..................	100	96
Children between 5 and 20 years of age	83.485	87.541

Total expenditures for schools........	$548,815	$621,161
Amount raised on grand list:		
By districts.....................	$382.841	$409.421
By towns........................	$86,295	$66,685
Average yearly cost of schools........	$176 43	$185 17
Average weekly cost per pupil:		
Enrolled.........................	$0 30	$0 32
Attending........................	$0 44	$0 44
Estimated cash value of school houses and grounds........................	$1,327,846	$1,339,864

In 1873–'4 teachers' institutes were held in all the counties, and were attended by 982 teachers. The state makes an annual appropriation of $1,500 for each of its three normal schools. In 1875–'6 that at Johnson had 4 instructors and 101 pupils; that at Randolph, 9 instructors and 250 pupils; and that at Castleton, 2 instructors and 75 pupils. The university of Vermont and state agricultural college, in Burlington, chartered in 1791 and opened in 1800, has an academical, an agricultural and scientific, and a medical department. The course of instruction in each of the first two departments occupies four years. In the agricultural and scientific department there are courses in agriculture and related branches, theoretical and applied chemistry, civil engineering, and metallurgy and mining engineering. Besides the usual academic degrees, the degrees of bachelor of philosophy, civil engineer, and mining engineer are conferred. All the courses in the academic and scientific departments are open to young women. In 1875–'6 there were 25 instructors, of whom 17 were in the medical school, and 153 students, of whom 62 were in the medical school. The university has a library of 16,000 volumes, a valuable museum, and the nucleus of a gallery of art. Middlebury college (Congregational), at Middlebury, was opened in 1800, and in 1875–'6 had 8 instructors, 53 students, a library of 18,000 volumes, and a valuable cabinet of natural history. Norwich university is a military college under the patronage of the Episcopalians, at Northfield. It was opened in 1834, and in 1875–'6 had 6 instructors and 41 students. Other prominent institutions of learning are the Vermont Episcopal institute in Burlington, the Vermont conference seminary and female college (Methodist) in Montpelier, Green Mountain seminary (Baptist) at Waterbury Centre, Goddard seminary (Universalist) at Barre, and St. Johnsbury academy at St. Johnsbury.—The total number of libraries in 1870 was 1,792, containing an aggregate of 727,263 volumes. Of these, 1,056 with 405,536 volumes were private, and 736 with 321,727 other than private, including the state library, 14,158; 82 town, city, &c., 52,368; 4 court and law, 3,023; 58 school, college, &c., 38,735; 544 Sabbath school, 182,840; 11 church, 8,517; 3 in charitable and penal institutions, 1,408; and 33 circulating, 20,678. In 1876 the state library at Montpelier had 17,000 volumes. The total number of newspapers and periodicals in 1870 was 47, having an aggregate circulation of 71,390 and issuing annually 4,055,300 copies. There were 3 daily, with a circulation of 3,190; 1 semi-weekly, 2,200; 43 weekly, 56,200; and 1 monthly, 12,000. In 1875 the total number was 68, including 6 daily, 57 weekly, and 5 monthly.—The total number of religious organizations in 1870 was 699, having 744 edifices with 270,614 sittings and property valued at $3,713,530. The denominations were:

DENOMINATIONS.	Organizations.	Edifices.	Sittings.	Property.

—The first white settlement in what is now Vermont was made in 1724 by the erection of

Fort Dummer near the present site of Brattleboro, which was then supposed to be in Massachusetts. From this fort and from Charlestown, N. H., troops were sent against the French in the war of 1745, and the fertile lands along the upper Connecticut, the Winooski, and Otter creek attracted their attention. The tide of emigration began to set in about 1760, and between that date and 1768 138 townships had been granted within the present limits of the state by Gov. Wentworth of New Hampshire, who claimed the jurisdiction and fee of the soil by virtue of the New Hampshire charter. The country west of the Connecticut was only known at that time by the name of "New Hampshire grants." A proclamation was made by the governor of New York, Dec. 28, 1763, claiming the territory under the grants from Charles II. to the duke of York, and ordering the sheriff to make returns of the names of those who had settled W. of Connecticut river under titles derived from New Hampshire. Gov. Wentworth issued a counter proclamation, March 13, 1764, declaring those claims obsolete, and maintaining the jurisdiction of New Hampshire. New York appealed to the king, who granted to that colony jurisdiction to the Connecticut river. The New York government now attempted to eject and dispossess the settlers from their lands. These proceedings were met by organized resistance on the part of the settlers, acting under the lead of Ethan Allen, Seth Warner, and others. In 1774 Gov. Tryon of New York issued a proclamation commanding Ethan Allen, Seth Warner, Remember Baker, Robert Cochran, Peleg Sunderland, Silvanus Brown, James Breakenridge, and John Smith to surrender themselves within 30 days under pain of conviction of felony and death without benefit of clergy, and offering a bounty of £150 for the capture of Allen and £50 for each of the others. The Vermont leaders retorted by offering a reward for the apprehension of the attorney general of New York. The commencement of the revolution caused a suspension of the controversy. In 1776 the Vermont settlers petitioned the provincial congress, then in session in Philadelphia, for admission into the confederacy; but New York opposed, and they withdrew. In 1777 Vermont declared her independence, and in July of the same year again applied to be admitted into the confederacy. Congress hesitated and temporized, and the people became indignant. Meantime the British generals endeavored to induce the Vermonters to declare allegiance to Great Britain. Aware of the importance of gaining time, and avoiding the troubles which would follow a bold decision in favor of the congress which had twice repulsed them, Ira Allen and others kept the British officers inactive till the theatre of the war was changed. In 1781 congress offered to admit Vermont with a considerable curtailment of her boundaries; but the people refused to come in on such terms, and for nine years she remained outside the Union. In 1790 New York revived the old question, and offered to relinquish all claims to lands in or jurisdiction over the state on the payment of $30,000. Vermont acceded to the proposition, and on March 4, 1791, was admitted into the Union. But though not one of the confederated colonies, and having no voice in their councils, the "Green mountain boys" had distinguished themselves during the revolution in some of the hardest fought and most successful battles and expeditions. Ethan Allen and his company of 83 men took Fort Ticonderoga, May 10, 1775. Allen and Warner participated in the invasion of Canada, and the former was taken prisoner and sent to England, while the latter with his regiment protected the retreat from Quebec, and adopted the measures which led to the capitulation of the British garrison at St. John's. In the battles on Lake Champlain their obstinate resistance gained them credit; and the two battles near Bennington, which were the primary causes of Burgoyne's defeat and surrender, immortalized the Green mountain boys. After the admission of the state into the federal Union, Vermont prospered beyond most of the other states. In the war of 1812 the governor refused to call out the militia, and issued a proclamation forbidding troops to leave the state. In spite of this the "Vermont volunteers" took an active part in the battle of Plattsburgh and the naval conflict on Lake Champlain, and added to their old renown for valor. As they were not regularly organized state troops, they were not entitled to bounty or pensions, but congress subsequently granted land warrants to the survivors. In 1837, at the time of the Canadian rebellion, a considerable body of the inhabitants of northern Vermont sympathized with the insurgents, and to the number of 500 or 600 crossed into Canada. A well armed British force was despatched to drive them off, and Gen. Wool, then in command on the frontier, gave them the alternative of returning and surrendering their arms to him, or, if they persisted and were compelled to retreat into Vermont, of being shot when they came over. After some hesitation they laid down their arms and dispersed. During the civil war Vermont furnished to the federal army 35,256 troops, being equivalent to 29,052 for three years. —The original constitution was adopted in 1777, and was modelled on that of Pennsylvania. It was amended in 1786 and again in 1793. The convention of 1793 embodied their amendments in the constitution instead of promulgating them separately; and this instrument has since been known as "the constitution of Vermont adopted by the convention" of 1793. The constitution of 1777 provided for a council of censors, consisting of 13 persons, to be chosen every seven years and to hold office one year. Their duty was to inquire whether the constitution had been preserved inviolate during the last septenary (including the year of their service), and whether the legislative and executive branches of government had performed their duty as guardians of the people, or assumed to themselves or exercised other or greater powers than they were entitled to by the constitution. They were also to inquire whether the public taxes had been justly laid and collected in all parts of the commonwealth, in what manner the public moneys had been disposed of, and whether the laws had been duly executed. For these purposes they had power to send for persons, papers, and records; they had authority to pass public censures, to order impeachments, and to recommend to the legislature the repeal of such laws as should appear to them to have been passed contrary to the principles of the constitution. These powers they had for one year from the day of their election. Thirteen councils of censors were held, the first in 1785 and the last in 1869. The constitutional convention of 1870 passed amendments making the terms of the principal state officers and the sessions of the legislature biennial and abolishing the council of censors. Until 1836 Vermont had no senate. Prior to that time the legislative power was vested in a house of representatives and an executive council, consisting of the governor, lieutenant governor, and 12 councillors chosen for one year by the people. This council, which had been created by the constitution of 1777, practically exercised legislative powers coördinate with the house of representatives. The constitution as amended in 1786 provided that all bills originating in the assembly should be laid before the governor and council for their revision and concurrence, or proposals of amendment; and in case such proposals of amendment were not agreed to by the assembly, the governor and council were empowered to suspend the passing of such bills until the next session of the legislature. (See supplement.)

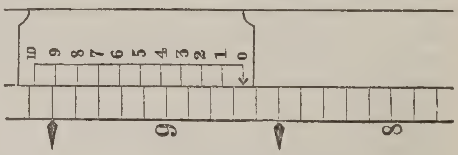
VERMONT, University of. See BURLINGTON.

VERNE, Jules, a French author, born in Nantes, Feb. 8, 1828. After studying law he wrote plays and operatic pieces, and was for some time secretary of the Théâtre Lyrique. In 1863 he became known by his *Cinq semaines dans un ballon*, a romance based upon the discoveries of modern science, and giving with a remarkable appearance of reality fanciful solutions of scientific problems. It has been translated into English, as have also his subsequent works of the same character, including "A Journey to the Centre of the Earth," "Twenty Thousand Leagues under the Sea," "From the Earth to the Moon," "Dropped from the Clouds," and "The Mysterious Island." One of his most popular works is the *Tour du monde en* 80 *jours* ("Around the World in Eighty Days"), which was dramatized in 1874, and had a great success at the Porte Saint-Martin theatre, Paris, and in the United States. He has also published with Théophile Lavallée an illustrated geography of France (1867-'8).

VERNET, the name of a family of French painters. The records of Avignon for 1669 mention André Vernet, a painter. ANTOINE, a decorative painter, two panels by whom are now in the museum of Avignon, was born there in July, 1689, and died Dec. 10, 1753. By his wife, Marie Thérèse Garnier, he had 22 children. An account of the eldest son is given below. Of the others, ANTOINE IGNACE, born June 7, 1726, went to Naples in 1746, and died there before 1775. He was an excellent painter of marine subjects, and especially of eruptions of Vesuvius. FRANÇOIS GABRIEL, born March 15, 1728, painted religious subjects. One of his pictures is in the church of St. Agricol, Avignon. ANTOINE FRANÇOIS, born March 12, 1730, a marine and landscape painter, was appointed painter of the royal buildings, and decorated the châteaux of Versailles, Fontainebleau, and Choisy. He died in Paris, Feb. 15, 1779. A daughter, AGATHE FAUSTINE, born June 25, 1723, married Honoré Guibert, an eminent sculptor, and her children and the children of her brothers mentioned above became more or less eminent as painters, sculptors, and jewellers. **I. Claude Joseph,** known as Joseph Vernet, eldest son of Antoine, born in Avignon, Aug. 14, 1714, died in Paris in December, 1789. He was first instructed by his father, then by able masters at Aix, and his rapid progress interested some wealthy patrons in Avignon, with whose assistance he was sent to Italy in 1734 to study historical painting. The vessel being overtaken by a terrible storm, he was lashed to the mast, and the scene presented to his view decided his career. After a few years he was considered the first marine painter in Europe, and from about 1739 the most distinguished men in Rome were his patrons and friends. Painting rapidly, he was yet unable to fill all his orders. In 1745 he married Virginia Parker, the daughter of an Irish emigrant, commander of the pope's galleys. He was made a member of the academy of St. Luke, and, with the exception of two visits to Marseilles in 1751 and 1752, remained for 20 years in Italy. In 1753 he returned to France, became a member of the academy of painting, and was commissioned by the king to paint the seaports of France. Travelling from port to port, he finished 15 of the 20 pictures ordered, when the breaking out of war and his disgust with a nomadic life induced him to resign the office and settle in Paris. Every crowned head in Europe became his patron, and he labored incessantly until his death. His pictures are scattered all over Europe, and most of them have been engraved. **II. Antoine Charles Horace,** known as Carle Vernet, son of the preceding, born in Bordeaux, Aug. 14, 1758, died in Paris, Nov. 28, 1836. On account of his delicate health his father kept him with himself, instructed him in painting, and allowed him great freedom. He became passionately fond of horses, and his pictures of them were considered masterpieces.

After once failing, he gained the great prize of the academy and went to Rome, but remained only a few months. He was subject to fits of melancholy bordering on insanity. Returning to France, he resumed his art, and marriage and a happy domestic life cured him of his melancholy. In 1804 he exhibited "The Battle of Marengo," which French critics regard as the commencement of the modern French school of military painting. This was followed by paintings of the principal battles of Napoleon. His smaller pictures, and especially his caricatures ridiculing the allies, were engraved in great numbers by the first artists of Paris. Throughout life he was remarkable for his industry, for his fine musical taste, and for his engaging social traits. **III. Jean Émile Horace,** known as Horace Vernet, son of the preceding, born in Paris, June 30, 1789, died there, Jan. 17, 1863. His education, both literary and artistic, was very irregular and unsystematic. His father imbued him with his own tastes for horses, military subjects, and caricatures. He was skilled in all bodily exercises. In 1807 he was made a conscript, but was released after his marriage with Mlle. Louise Pujol in 1810. Soon after he exhibited his first military painting, "The Capture of a Redoubt." In this picture he broke away from the conventional classicism of David and his school, and henceforth through life he painted military subjects so as to represent the reality presented by observation and experience. In 1811 he was appointed designer to the depot of war. At the exhibition of 1812 he gained a first medal by "The Taking of an intrenched Camp." As a sub-lieutenant of the national guard he participated in the defence of the barrier of Clichy, a painting of which he afterward executed. After the restoration of the Bourbons, the royal family gave him commissions which he executed, but at the same time during many years he continued to paint pictures and make designs of scenes in the history of the *grande armée* and of the life of Napoleon, which the court regarded as almost seditious. The "Dog of the Regiment," "Barrier of Clichy," "Soldier of Waterloo," "Death of Poniatowski," "Bivouac of Col. Moncey," and many others became immensely popular, and engravings by the first artists of Paris and the newly discovered art of lithography made them known in every cottage of France. At the exhibition of 1822 most of his paintings were refused admission on account of their Bonapartist tendency. He then opened an exhibition in his own studio, which was attended by crowds. Louis Philippe, then duke of Orleans, and Charles X., both anxious to secure the friendship of so popular an artist, patronized him. In 1826 he was made a member of the institute, and in 1828 director of the French academy in Rome. After the accession of Louis Philippe Vernet was for a time the representative of the French government at Rome. In 1833 he visited Algiers, and in 1835 returned to Paris. He visited St. Petersburg in 1836, '38, and '42, Algiers in 1837, '45, and '53, and Egypt, Syria, Palestine, and Turkey in 1839-'40. On his travels he wrote many letters, which were published by M. Durande in 1864. In 1841 Vernet published a small work *Du droit des peintres et des sculpteurs sur leurs ouvrages*, and in 1848 a *mémoire*, previously read before the institute, *Des rapports entre le costume des Hébreux et des Arabes modernes*, a subject which he had illustrated in a series of paintings, "Rebecca at the Well," "The Good Samaritan," and others. But from 1836 to his death his principal labor was devoted to painting battle pieces and pieces illustrative of the life of the Arabs of Algiers. Among the latter are the "Lion Hunt," "Council of Arabs," and "Arab Mother rescuing her Child from a Lion;" among the battle pieces, Jena, Friedland, Wagram, and Fontenoy, and a whole series representing the exploits of the French in Algiers, the "Capture of the Smala," "Battle of Isly," and many others, some of them of immense size. He also made hundreds of designs for illustrated works. At the universal exposition of 1855 he received the grand medal of honor. In 1862 he had begun a religious painting in his villa at Hyères. A severe fall led to his return to Paris, where he expired after several months of great suffering. His only child, Louise, married the painter Paul Delaroche, and left two sons, Horace and Philippe, who by a legal authorization assumed the name Delaroche-Vernet.—See *Joseph, Carle et Horace Vernet, correspondance et biographies*, by Durande (Paris, 1865).

VERNIER, an instrument attached to a scale for the purpose of measuring spaces smaller than those into which the scale is actually divided. The principle of the vernier will be best understood from the figure. The lower scale, marked 8-9, is part of a scale of inches divided into tenths. The upper scale, marked 0 . . . . 10, is the vernier, and is movable upon the scale of inches. The ten divisions of the vernier are exactly equal to nine subdivisions of the scale of inches, consequently each division of the vernier equals $\frac{9}{10}$ of $\frac{1}{10}$ of an inch, or 0·09 inch. When the 0 of the vernier coincides with one of the marks of the principal scale, the 1 of the vernier will fall 0·01 inch short of the next division of the principal scale, the 2 of the vernier will fall 0·02 inch short of the next division of the principal scale, and so on. If we shove the vernier forward 0·01 inch, its 1 will exactly coincide with one of the



Vernier.

subdivisions of the principal scale; if we shove it forward 0·02 inch, its 2 will exactly coincide, and so on. In the figure the vernier has been pushed forward until its 0 falls between 8·6 and 8·7 inch, and is supposed to be at the point to which we wished to measure. Looking along the vernier, we see that its division marked 7 exactly coincides with one of the divisions of the principal scale. The correct reading of the whole apparatus then is 8 inches, 6 tenths, and 7 hundredths, or 8·67. In what are sometimes called "retrograde verniers" 10 divisions of the vernier correspond to 11 of the principal scale, and are numbered and read in the opposite direction to the principal scale, but the principle involved is the same. Other ratios besides 9 : 10 or 10 : 11 between the vernier and the principal scale are employed in different instruments, according to the purposes for which they are intended. When great delicacy is required, the measuring instrument is furnished with a microscope, in order to perceive more accurately what lines exactly coincide, and also with two or three verniers, and all are read and the mean is taken. The vernier derives its name from Peter Vernier of Burgundy, an engineer, who invented the instrument in 1631.

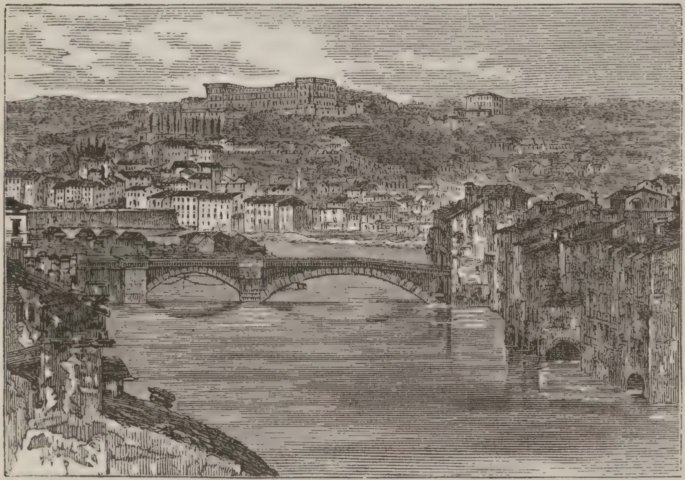
VERNON. I. A S. W. parish of Louisiana, separated from Texas on the west by Sabine river, and drained by Bayou Lanacoco and affluents of the Calcasieu river; area, about 1,450 sq. m.; pop. in 1875, 4,259, of whom 412 were colored. The surface is generally level, and much of the soil is fertile. There are extensive prairies that pasture large herds of cattle. The chief productions are Indian corn, sweet potatoes, and cotton. Capital, Leesville. **II.** A S. W. county of Wisconsin, separated from Iowa and Minnesota on the west by the Mississippi river, and drained by Raccoon and Kickapoo rivers and other streams; area, about 800 sq. m.; pop. in 1870, 18,645. The surface is undulating and consists largely of prairies; the soil is fertile. The chief productions in 1870 were 552,594 bushels of wheat, 290,846 of Indian corn, 445,526 of oats, 30,709 of barley, 82,349 of potatoes, 61,633 lbs. of wool, 484,741 of butter, 92,068 of hops, 37,647 of maple sugar, and 20,237 tons of hay. There were 4,676 horses, 5,560 milch cows, 10,924 other cattle, 21,456 sheep, and 15,612 swine; 8 manufactories of carriages and wagons, 5 flour mills, 11 saw mills, and 2 wool-carding and cloth-dressing establishments. Capital, Viroqua. **III.** A W. county of Missouri, bordering on Kansas, and drained by the Osage river and its affluents; area, about 700 sq. m.; pop. in 1870, 11,247, of whom 82 were colored. The surface is undulating and the soil fertile. It is intersected by the Missouri, Kansas, and Texas railroad. The chief productions in 1870 were 56,934 bushels of wheat, 476,230 of Indian corn, 98,793 of oats, 32,153 of potatoes, 145,775 lbs. of butter, 15,450 of wool, and 3,925 of tobacco. There were 4,168 horses, 4,202 milch cows, 11,361 other cattle, 6,822 sheep, and 15,099 swine. Capital, Nevada.

VERNON, Edward, an English admiral, born in Westminster, Nov. 12, 1684, died at his seat of Nacton in Suffolk, Oct. 29, 1757. He served in the expedition of Admiral Hopson, which on Oct. 12, 1702, destroyed the French and Spanish fleets off Vigo; and he was present at the sea fight off Malaga between the French and English in 1704. He attained the rank of rear admiral in 1708, and remained in active service till 1727, when he was elected to parliament for Penryn, and in the succeeding parliament, which lasted from 1734 to 1741, he sat for Portsmouth. In the house he loudly condemned all the measures of the ministry, without respect of persons, and in a debate declared that Porto Bello could be taken with six ships. For this remark he was extolled all over the kingdom, and to silence the general clamor the ministry sent him to the West Indies with the rank of vice admiral of the blue. In November, 1739, he appeared off Porto Bello with six men-of-war, and the city was taken the day after the attack began, the English losing only seven men. In January, 1741, he sailed from Jamaica with 29 ships of the line and 80 smaller vessels, having on board 15,000 sailors and 12,000 land troops, and on March 4 appeared before Cartagena, but was repulsed with loss, and sickness destroyed those who escaped. But Vernon did not lose his popularity in England, and in 1742 planned an expedition against Panama. He had been elected to the parliament of 1741 from Penryn, from Rochester, and from Ipswich. He accepted the representation of Ipswich, and was returned to the parliaments of 1747 and 1754. During the invasion of the pretender in 1745, he was employed to guard the coast of Kent and Sussex; in this he gave satisfaction, but on account of a quarrel with the admiralty his name was struck from the list of admirals.

VERNON, Robert, an English collector of paintings, born in 1774, died in London, May 22, 1849. He amassed a fortune in commercial pursuits, a great portion of which was devoted to the purchase of pictures, principally by British artists. As his collection grew beyond the capacity of his house, he presented the most valuable portion to the government in December, 1847. The British national gallery, founded in 1824, contained at the time of Mr. Vernon's donation but 41 pictures by native artists, and the Vernon collection, as it is still called, may be considered the nucleus of a national gallery of British art on a considerable scale. It was for some time exhibited at Marlborough house, but has now been removed to the South Kensington museum. It comprises 162 pictures, a marble group by Gibson of Hylas and the nymphs, and a number of busts.

VÉRON, Louis Désiré, a French journalist, born in Paris, April 5, 1798, died there, Sept. 27, 1867. He practised medicine in the foundling hospital and other institutions from about 1821 till 1828, and made a fortune by the lozenges of his deceased friend Regnauld. In 1829 he founded the *Revue de Paris.* In 1831 he became director of the opera, put on the stage works by Meyerbeer, Auber, and Halévy, and retired with large means at the end of 1835. In 1838 he was an unsuccessful candidate for the chamber of deputies. He purchased an interest in the *Constitutionnel* at the suggestion of Thiers, whose organ it was, and in 1844 became sole proprietor. In 1849 he deserted Thiers for Louis Napoleon, whose *coup d'état* of Dec. 2, 1851, he applauded; and he was elected as an official candidate to the legislative body, and reëlected in 1857. In January, 1862, he finally left the *Constitutionnel.* His works include *Mémoires d'un bourgeois de Paris* (7 vols., 1854–'6); *Cinq cent mille francs de rente,* a romance (2 vols., 1855); *Quatre ans de règne: Où allons-nous?* (1857); and *Les théâtres de Paris depuis* 1806 *jusqu'en* 1860.

VÉRON, Pierre, a French writer, born in Paris in 1833. He was the editor of the *Revue de Paris* from 1854 till its suppression in 1858, and subsequently was one of the editors of the *Charivari.* He is a voluminous writer on metropolitan life, one of his most recent works being *Le sac à la malice* (1875).



Verona.

VERONA. **I.** A N. E. province of Italy, in the W. part of Venetia, bordering on Tyrol and the provinces of Vicenza, Padua, Rovigo, Mantua, and Brescia, from which it is separated by the Mincio and the lake of Garda; area, 1,061 sq. m.; pop. in 1872, 367,437. The Adige flows through the centre of the province, and there are altogether 9 navigable rivers and 13 canals, and many streams and torrents. The N. part is mountainous; the other parts are level or undulating. There are marshes in the south, but the soil is generally fertile, and the pastures rich. The productions include grain, rice, fruit, flax, silk, oil, and wine, and several minerals. Lake Garda and the rivers are well stocked with fish, and game is plentiful. The principal mineral springs are at Caldiero. The chief towns, besides the capital, are Legnago, Villafranca, and Caprino. **II.** A city, capital of the province, at the foot of the last spurs of the Tyrolese Alps, on both sides of the Adige, surrounded by groves and villas, in one of the finest regions of N. Italy, 62 m. W. of Venice; pop. in 1872, 67,080. The Adige is crossed by many bridges, the finest and most recent connecting with the railway station, and floating mills are moored in the river. The fortifications were begun by the emperor Gallienus and continued by Theodoric and Charlemagne. The Scala dynasty erected forked battlements and towers, and the Venetians originated the outworks. Sammicheli introduced in the 16th century the triangular and pentangular bastions, and his plans made the whole system of fortification a marvel of modern engineering. His ramparts and bastions were almost entirely destroyed under the treaty of Lunéville (1801), but the Austrians subsequently made it a formidable stronghold. Sammicheli's celebrated gates, the Porta Nuova and Porta del Palio or Stuppa, still remain, as well as vestiges of the Roman and subsequent walls. The principal square is the piazza dei Signori, with the palazzo del Consiglio, the colossal statue of Dante erected May 14, 1865, the Scala palaces occupied by the local authorities, and a campanile consisting of one magnificent piece of brickwork, 300 ft. high. The piazza delle Erbe, or vegetable market, was the forum of the republican era of the city. Besides the Corso, there are several fine avenues, but most of the streets are unsightly. Conspicuous among 48 churches is the cathedral of Sta. Maria Matricolare, mostly rebuilt in the 12th century, with exceedingly rich chapels and monuments, and with Titian's "Assumption." Attached to the cloister is the Capitolare library, with important collections of historical, theological, and legal works and manuscripts. Sant' Anastasia is one of the finest Gothic churches in the whole country, though the front is not finished. San Zenone is the most characteristic specimen of mediæval ecclesiastical architecture; it has a rich interior of singular grandeur, and the belfry of brick and marble, with arches and turrets, is one of the most remarkable of its kind. San Fermo, called *maggiore* from its size, dates from the 8th century, and has remarkable monuments. The interior of San Giorgio Maggiore was embellished by Sammicheli, and contains paintings by Paul Veronese and other masters. Close to Sta. Maria Antica are the tombs of the Scala family. Verona is emphatically a city of palaces; several, such as the Canossa, Pompei, and Maffei (now Tresa) palaces, are among Sammicheli's masterpieces. The palace of the resident bishop (*vescovado*) was principally restored in the 14th century. Castel Vecchio and the adjoining bridge were built by Cangrande II. The picture gallery has been removed from the Consiglio to the Pompei alla Victoria palace in the via di Porto at the Campo Marzio, facing the Adige; it contains large collections, chiefly paintings by Veronese masters. The most imposing Roman antiquity in Verona is the ruined amphitheatre, contemporary with the Colosseum of Rome, built of marble, originally 513 ft. long, 410 ft. broad, with a length of arena of 248½ ft., and 100 ft. high, and accommodating 22,000 spectators. Part of it is intact; the interior is used as a circus, and the arcades for shops. Among numerous other Roman relics are fragments of a theatre and the Porta de' Borsari and Arco de' Leoni. Verona has associations with Dante, Petrarch, and Shakespeare's "Romeo and Juliet." The tomb of Juliet has long been destroyed, though one is still shown for the gratification of tourists. The city has a lyceum, a gymnasium, a theological seminary, a technical institute, an academy of painting and sculpture, a city library, an agricultural academy, a society for bee culture, and a private institution for indigent girls, who excel in silk and gold embroideries and artificial flowers. Among the many art collections, the Maffei is rich in inscriptions, statues, and vases. Silk, woollen, linen, and other goods are made. There is an active trade in these, and in grain, oil, and sumach, which has much increased since the opening in 1867 of the Brenner railway, which makes Verona the centre of mercantile communication with Germany, as it formerly was of military movements in N. E. Italy.—Verona was originally an important town in Gallia Transpadana, and it became a flourishing Roman colony with the surname of Augusta. In A. D. 312 it was conquered by Constantine the Great in his march from Gaul, and in 489, on the defeat of Odoacer, it was taken by Theodoric the Great, who often held his court at Verona. Charlemagne captured it in 774, and it afterward became a free city. The Scala family obtained supreme power in 1260, and were overthrown in 1387 by Giovanni Galeazzo Visconti of Milan. Cangrande, Dante's friend, was the most celebrated ruler of the former house. (See SCALA, and CANE I. DELLA SCALA.) In the beginning of the 15th century it was annexed to Venice. The French took Verona in 1796, and ceded it in 1797 to Austria, but again held it from 1805 to 1814, when it was recovered by Austria. The congress of Verona (October to December, 1822), over which Metternich presided with Gentz for his secretary, aimed at the termination of the disturbed condition of Spain and Turkey and of revolutionary agitation in Europe, and its principal result was the French intervention in Spain in the following year. In 1866 Verona was incorporated with the kingdom of Italy.—See Maffei's *Verona illustrata* (Verona, 1731–'2; new ed., 8 vols., 1792–3); Ronzani's *Le antichità de Verona* (1833); and G. da Persico's *Descrizione di Verona e della sua provincia* (1838).

VERONESE, Paul. See CAGLIARI.

VERPLANCK, Gulian Crommelin, an American author, born in New York, Aug. 6, 1786, died there, March 18, 1870. He graduated at Columbia college in 1801, studied law, and passed several years in European travel. In 1820 he became a member of the New York legislature, and not long afterward professor of the evidences of Christianity in the general Protestant Episcopal seminary in New York. From 1825 to 1833 he was a member of congress, and afterward several times of the state senate. He published "The State Triumvirate, a Political Tale," "Bucktail Bards," and "The Epistles of Brevet Major Pindar Puff" (1819), political pamphlets chiefly aimed at De Witt Clinton; "Essays on the Nature and Uses of the Various Evidences of Revealed Religion" (1824); nearly half of the annual in prose and verse called "The Talisman" (3 vols., 1827–'30); "Discourses and Addresses on Subjects of American History, Arts, and Literature" (1833); an edition of Shakespeare (3 vols., 1844–'7); and several college orations, the best known of which is "The American Scholar," delivered at Union college in 1836. He prepared also for 15 years nearly all the annual reports of the commissioners of emigration, of which board he was president.

VERRAZZANO, Giovanni da (called also VERRAZANI), a Florentine navigator, born about 1485, executed at Puerto del Pico, Spain, in November, 1527. He was of a good family of the Val di Greve near Florence, and went to France, where he found employment as a navigator. References in French annals make it possible that he visited the northern coast of America as early as 1508. He soon became famous as a corsair against the Spaniards and Portuguese, made valuable captures in 1521, and in 1522 captured the treasure ship in which Cortes was sending to Charles V. the rich spoils of Mexico, valued at more than $1,500,000. His next depredation on the Portuguese roused Spain and Portugal against him, and he was finally captured in September or October, 1527, taken to Spain, and executed by the emperor's orders. In 1556 Ramusio published in his collection of voyages a letter which he ascribed to Verrazzano, purporting to have been written at Dieppe, July 8, 1524, and giving to Francis I. an account of a voyage to the coast of North America and its exploration from lat.

34° to 50°. This letter was gradually received as authentic, and Verrazzano mentioned in American history as the earliest French explorer of the coast, and possibly the first to enter New York bay. Its authenticity was first attacked in 1864 by T. Buckingham Smith, who identified Verrazzano with the corsair Juan Florin of Spanish accounts, but was maintained by J. Carson Brevoort in "Verrazzano, the Navigator" (8vo, New York, 1874). Henry C. Murphy, after careful researches, rejects the letter as spurious in his "Voyage of Verrazzano, a Chapter on the Early History of Maritime Discovery in America" (8vo, New York, 1875). The attempted fraud is not attributed to Verrazzano, but to some one of his countrymen, anxious to secure for Italy the glory more credibly belonging to Estevan Gomez, a Portuguese, who went as chief pilot with Magellan, and has the credit of visiting the coast of Carolina and entering several rivers in 1525.

VERRES, a Roman governor of Sicily, put to death in 43 B. C. He was the son of a Roman senator, and in 82 became quæstor to Cn. Papirius Carbo, but subsequently deserted the Marian faction to which Carbo belonged, and joined that of Sulla, who gave him a share of the confiscated estates and sent him to Beneventum. He was pro-quæstor to Dolabella, prætor of Cilicia, 80–79, and participated in the iniquitous acts of that rapacious governor, but afterward turned against him, and contributed by his evidence to his conviction. With the money obtained by plundering the provinces, he was elected prætor in 74, and became by lot *prætor urbanus.* After managing the affairs of the city in defiance of all justice and law, he obtained at the expiration of his term of office the administration of Sicily, then the wealthiest province of the republic. In this island he remained three years, during which time he amassed enormous wealth, and fairly desolated Sicily by his rapacity. The Sicilians intrusted to Cicero the prosecution of Verres, the importance of which was more due to political reasons than to the character of the criminal. Verres was defended by Hortensius, and supported by the Scipios and the Metelli. The decision was to be made by the senate, on whom the judicial power taken from the equites had been conferred by Sulla; and on the result of this trial depended in great measure the continuance of this power, inasmuch as there was a strong feeling among the people in favor of a reform of the court. The adherents of Verres spared nothing in the shape of promises, threats, and bribes, in order to secure his acquittal; but their efforts were useless, and before the nine days which were given to the hearing of evidence were over, he fled to Massilia, where he remained in exile 27 years. He was put to death by the proscription of Antony.

VERROCCHIO, Andrea, an Italian artist, born in Florence in 1432, died there in 1488. He was at once a sculptor, a goldsmith, and a painter, but most distinguished as a sculptor. Perugino and Leonardo da Vinci were his pupils. He was the first to take moulds of the human form to aid in designing. The pictures attributed to him are generally spurious.

VERSAILLES, a city of France, capital of the department of Seine-et-Oise, and legally of the republic, 10 m. S. W. of the centre of Paris; pop. in 1872, 61,686. It is built with great regularity, the streets crossing each other at right angles, and has a monotonous appearance. The main thoroughfares are the avenues de Paris, St. Cloud, and Sceaux, the place d'Armes, and the boulevard de la Reine. The principal churches are those of Notre Dame and St. Louis, and there is an English chapel. Among the public buildings are the tennis court, famous for the short part which it played in the beginning of the revolution of 1789, a lyceum, and other schools and hospitals. Versailles derives its celebrity from the royal palace built by Louis XIV. on the site of Louis XIII.'s hunting lodge, where that monarch and his successors resided till the revolution. The marble court and the interior, which is 105 ft. long and 79 ft. high, are remarkable for extraordinary magnificence and grandeur, especially the vast museums or galleries, with statues and pictures of the great historical personages and events of the country, described in Gavard's *Galeries historiques de Versailles* (13 vols., Paris, 1835–'48). Connected with the palace are chapels, an extensive library, and magnificent gardens, where fountains playing on Sundays attract multitudes of visitors from Paris. Louis XV. added the theatre and other buildings. The park connects with the Grand Trianon and the Petit Trianon palaces; the latter was the favorite residence of Marie Antoinette. Adjoining the palace are the military hospital and the artillery and cavalry barracks. The most brilliant periods of the reigns of Louis XIV. and Louis XV., as well as the beginning of the catastrophe under Louis XVI., are associated with the residence of those monarchs at Versailles. The definitive treaty which terminated the American struggle for independence was concluded here, Sept. 3, 1783, and the states general were opened here May 5, 1789. Napoleon I., Louis XVIII., and Charles X. attempted to repair the damage inflicted upon the palace during the revolution, and under Louis Philippe it was fully restored. During the Franco-German war of 1870 Versailles became the headquarters of the Germans; the king of Prussia was proclaimed here (in the palace) emperor of Germany, Jan. 18, 1871; the capitulation of Paris was concluded here ten days later, and the preliminary treaty of peace on Feb. 26, and the national assembly and seat of government were removed hither from Bordeaux. Many prisoners were transferred to Versailles during the war with the commune, and shot in the neighboring plain of Satory. The constitutional provisions of February, 1875, made Versailles the legal capital, though it is practically only the seat of the senate and assembly, which occupy chambers in the palace.

VERTEBRA. See Skeleton.

VERTEBRATA, a name applied by Lamarck to the highest branch of the animal kingdom, from its being characterized by a bony or cartilaginous internal skeleton, of which the most essential and persistent portion is the vertebral column or spine. (See Comparative Anatomy, Philosophical Anatomy, and Skeleton.) Aristotle had made the distinction of ἔναιμα (blood animals) and ἄναιμα (bloodless animals), corresponding respectively to the vertebrata and invertebrata of Lamarck. Oken called the vertebrates *sarcozoa* or flesh animals; Ehrenberg, *myeloneura;* De Blainville, *osteozoaria;* and Owen, *myelencephala.* These various terms describe very accurately the relations of the skeleton, red blood, muscles, and cerebro-spinal nervous centres, characteristic of fishes, batrachians, reptiles, birds, and mammals. The essential character of the spinal column is to have a distinct cavity above the axis for the nervous centres, and another below for the organs of vegetative life, both circumscribed by complicated bony arches. Vertebrates are the doubly symmetrical type of Von Baer, their embryological development producing identical parts arising on both sides of an axis, growing upward and downward and shutting up along two lines, the inner layer of the germ being enclosed below and the upper above; Van Beneden calls them *hypocotyledones* or hypovitellians, from the vitellus or yolk entering the body from the under or ventral side. Lamarck also styles them intelligent animals, but comparative psychology is not sufficiently advanced to enable us to distinguish in this way between the sensations of a fish and a cephalopod or an insect. In vertebrates reproduction is sexual, without normal hermaphroditism, and the jaws move vertically and not laterally. Ehrenberg divides vertebrates into *nutrientia*, or warm-blooded, and taking care of their young, like mammals and birds; and *orphanozoa*, cold-blooded, taking no care of their young, like reptiles and fishes; but some of the latter do take care of their young, in a different or in the same way as the former division. The classes of vertebrates, according to Agassiz, are: 1, myzonts (myxinoids and cyclostomes); 2, fishes proper; 3, ganoids (sturgeons, &c.); 4, selachians (sharks and rays); 5, amphibians (frogs, salamanders, &c.); 6, reptiles; 7, birds; and 8, mammals. In this type, to use his words ("Atlantic Monthly," January, 1862, p. 12), "the head is the prominent feature; it is, as it were, the loaded end of the longitudinal axis, so charged with vitality as to form an intelligent brain, and rising in man to such predominance as to command and control the whole organism." The classification adopted by Prof. Owen is as follows: I., *pisces*, with the subclasses *dermopteri* (*cirrostomi*, *cyclostomi*), *teleostomi* (*malacopteri*, *anacanthini*, *acanthopteri*, *plectognathi*, *lophobranchii*, *ganoidei*), *plagiostomi* (*holocephali*, *plagiostomi*), and *protopteri* (*lepidosiren*); II., *amphibia*, with the orders *ophiomorpha*, *ichthyomorpha*, *theriomorpha*, and *labyrinthodontia ;* III., *reptilia*, with the orders *chelonia*, *lacertilia*, *ophidia*, *crocodilia*, and the extinct *ichthyopterygia*, *sauropterygia*, *anomodontia*, *dinosauria*, and *pterosauria ;* IV., *aves*, divided into the three sections of *altrices* (embracing the *raptores*, *scansores*, *volitores*, and *cantores*), *præcoces* (*rasores*, *cursores*, *grallatores*, *natatores*), and *uroioni* (archæopteryx); V., *mammalia*, with the four subclasses of *archencephala* (*bimana*), *gyrencephala* (*quadrumana*, *carnivora*, *artiodactyla*, *perissodactyla*, *proboscidia*, *toxodontia*, *sirenia*, *cetacea*), *lissencephala* (*bruta*, *cheiroptera*, *insectivora*, *rodentia*), and *lyencephala* (*marsupialia*, *monotremata*). Huxley makes the vertebrata his sixth subkingdom, characterized by the body composed of definite segments arranged longitudinally or one behind the other. The main masses of the nervous system are on the dorsal aspect, and are completely shut off from the general body cavity. The limbs, when present, are turned away from that side of the body on which the main nervous masses are situated, and are never more than four. He divides the vertebrata into three primary provinces, viz.: *ichthyopsida* (fishes and amphibians), *sauropsida* (reptiles and birds), and *mammalia.* His classes are the following: I., *pisces*, with the orders *pharyngobranchii*, *marsipobranchii*, *teleostei*, *ganoidei*, *elasmobranchii*, and *dipnoi ;* II., *amphibia*, with the orders *urodela*, *labyrinthodontia*, *gymnophiona*, and *anoura ;* III., *reptilia*, with the orders *chelonia*, *lacertilia*, *ophidia*, *crocodilia*, *plesiosauria*, *ichthyosauria*, *dicynodontia*, *ornithoscelida*, and *pterosauria ;* IV., *aves*, with the groups *ratitæ* (with the sternum devoid of a keel), *carinatæ* (sternum provided with a keel), and *saururæ ;* V., *mammalia*, with the groups *ornithodelphia* (*monotremata*), *didelphia* (*marsupialia*), and *monodelphia* (*edentata*, *ungulata*, *toxodontia*, *sirenia*, *cetacea*, *hyracoidea*, *proboscidea*, *carnivora*, *rodentia*, *insectivora*, *cheiroptera*, and *primates*). For further details of his classification of birds, see Ornithology. Modifications of these classes and orders are almost as numerous as the specialists who have investigated them, and chiefly of interest to students of the history of zoölogy.

VERTIGO (Lat., from *vertere*, to turn), a common symptom of cerebral disturbance, with or without obscurity of vision, in which objects appear to turn round; besides the abnormal subjective sensations, there may be disordered movements prompted thereby. It may arise from too much or too little blood sent to the brain; from poisons in the circulation, as in alcoholic and other intoxication; and from lesions of the sensorial centres or the nerves therewith connected. The effect is that the intelligence is not able to correct the erroneous suggestions of the senses. It is most commonly a symptom of congestion of the brain, and often indicates an approaching attack of apoplexy, epilepsy, or paralysis.

VERTNER, Rosa (JEFFREY), an American authoress, born near Natchez, Miss. She is the daughter of John Griffith, but was adopted by an aunt, whose name Vertner she took. She was educated in the seminary under the charge of Bishop Smith, in Lexington, Ky. She married Claude M. Johnson, and after his death Alexander Jeffrey of Lexington, where she now resides (1876). In 1850 she became a contributor to the Louisville "Journal," and afterward to numerous periodicals, and in 1857 a volume of her poems was published in Boston. She has also published "Woodburn," a novel (New York, 1864), and several tales and poems under the signature of Rosa, which have not been collected.

VERTOT, René Aubert de, a French historian, born at the château of Benetot, Normandy, Nov. 25, 1655, died in Paris, June 15, 1735. He was successively a Capuchin and Premonstratensian monk and a secular priest, in 1701 became a member of the academy of inscriptions, and was afterward historiographer of the knights of Malta and secretary to the duke and duchess of Orleans. His works, valued more for their style than for their accuracy, are: *Histoire des révolutions de Portugal* (Paris, 1689); *Histoire des révolutions de Suède* (2 vols. 12mo, 1696); *Histoire complète de l'établissement des Bretons dans les Gaules* (1710); *Histoire des révolutions arrivées dans le gouvernement de la république romaine* (3 vols. 12mo, 1719); and *Histoire des chevaliers hospitaliers de St. Jean de Jérusalem* (4 vols. 4to, 1726).

VERTUMNUS, or **Vortumnus,** an Etruscan or Sabine divinity, worshipped by the ancient Romans as the god who presided over the seasons, and the blossoming and bearing of trees and plants. He had the power of assuming any shape he pleased. Falling in love with Pomona, the goddess of garden fruits, he appeared to her in a variety of forms, and at last won her under the guise of a blooming youth. A *flamen* was appointed at Rome especially to superintend his worship; a festival called the Vortumnalia was celebrated in his honor on Aug. 23; and offerings were brought him of first fruits from the garden and wreaths of flowers. In works of art he was represented, like Saturn, with a pruning knife in his hand and a wreath of ears of corn on his head.

VERUS, Lucius. See ANTONINUS, MARCUS AURELIUS.

VERVAIN. See VERBENA.

VERVIERS, a town of Belgium, in the province and 14 m. E. S. E. of the city of Liége, on the Vesdre, near the Prussian frontier; pop. in 1873, 38,875. It contains fine churches and other public buildings, including a chamber of commerce, and has celebrated cloth manufactories, the annual products of which are valued at 100,000,000 francs, including those of the adjacent villages. One third is exported. There are more than 60 mills in the town and its vicinity, employing about 40,000 persons and 150 steam engines. The fortifications were destroyed by Louis XIV.

VESALIUS, Andreas, a Flemish physician, born in Brussels, Dec. 31, 1514, died in the island of Zante, Oct. 15, 1564. He was educated at Louvain, Montpellier, and Paris, and was early distinguished by his devotion to anatomical studies. In the last named city he became chief assistant of Gunther, and in 1536 discovered the origin of the spermatic blood vessels. The pursuit of practical anatomy was attended with so much difficulty and danger in France, that after returning to Louvain he joined the army of Charles V. of Germany, and went to Italy, where in 1540 he was made professor of anatomy in the university of Pavia, in 1543 in that of Bologna, and not long afterward in that of Pisa. In 1543 he published his great work on anatomy, *De Corporis Humani Fabrica* (fol., Basel; enlarged ed., 1555). In this Vesalius exposed the errors of the Galenian school, who relied for their knowledge of the anatomy of the human body upon the observations made in the dissection of the bodies of the lower animals. The work met with the fiercest opposition; nevertheless the author's reputation increased. About 1544 he was made chief physician to Charles V., and afterward to his son Philip II.; and the duties which devolved upon him gradually deprived him of all opportunity of increasing his knowledge of anatomy. In 1563 or 1564 he suddenly left Madrid to make a pilgrimage to Jerusalem, for reasons not known. On his arrival there he received an offer from the Venetian senate of the professorship of anatomy at Padua. On the voyage back he was wrecked on the island of Zante, where he died probably from fatigue and exposure. Besides his great work, he wrote *De Radicis Chinæ Usu Epistola* (Venice, 1546); *Anatomicarum Gabrielis Fallopii Observationum Examen* (1564); *Examen Apologiæ Fr. Putæi pro Galeno* (1564); and a paraphrase and translation of some of the works of the Arabic physician Rhazes. His complete works, together with a life, were published at Leyden in 1725 (2 vols. fol.), edited by Boerhaave and Albinus.

VESOUL, a town of France, capital of the department of Haute-Saône, at the junction of the Durgeon with the Colombine, about 190 m. S. E. of Paris; pop. in 1872, 7,597. The fortifications have been converted into promenades, and it has a church of the 18th century with a fine altar, a museum rich in Gothic and Roman antiquities, cavalry barracks, a lyceum, a normal seminary, a public library, a theatre, manufactories of turned ware and of cotton and silk goods, and trade in grain, cattle, leather, and iron ware. In the vicinity are many vineyards, iron works, and a mineral spring. On the adjoining Mt. La Motte (1,400 ft. high) is a statue of the Virgin, erected in 1854 as a memorial of the town's exemption from cholera. The Germans took Vesoul Oct. 18, 1870.

VESPASIAN (Titus Flavius Sabinus Vespasianus), a Roman emperor, born near Reate in the Sabine country, Nov. 17, A. D. 9, died there, June 24, 79. His father was a petty officer of the revenue, who died while the son was still young. Vespasian served in Thrace as military tribune, became quæstor in Crete and Cyrene, and subsequently ædile and prætor. In the reign of Claudius he went to Germany as *legatus legionis*, and in 43 held the same command in Britain, where he served under Aulus Plautius and under the emperor himself, and reduced the isle of Wight. Triumphal honors were granted him, and during the last two months of 51 he was made *consul suffectus*. Subsequently he governed Africa as proconsul. At the end of 66 he was sent by Nero to the East to take command of the army in the Jewish war. In two years he reduced all Judea except Jerusalem and some minor strongholds. His reputation now rose so high, that on the breaking out of the civil war between Otho and Vitellius after the death of Galba, the prefect of Egypt proclaimed Vespasian emperor at Alexandria, July 1, 69. The choice was immediately ratified by the legions of Judea, and not long afterward by the entire army of the East. His son Titus was left to put an end to the Jewish war, while one of his generals, Antonius Primus, marched at once into Italy, defeated the troops of Vitellius, and put Vitellius himself to death. In the mean time Vespasian had gone to Alexandria to cut off the supply of grain from Rome, but his recognition by the senate made the step unnecessary. In the summer of 70 he arrived in Italy, where his coming was hailed with great joy. His accession worked a great change in the condition of the empire. He maintained firm discipline among the soldiers, removed many unworthy senators and knights, restored order to the finances, and repaired the devastations of the recent civil commotions. He rebuilt the capitol, erected a temple to Peace, and began the Flavian amphitheatre, which was afterward called the Colosseum. The foreign wars of his reign were successful. The rebellion of the Batavi under Claudius Civilis was put down; Titus completed the conquest of Judea; the governor of Syria took possession of Commagene; and a war was carried on in Britain with great success. In 71 the temple of Janus was closed, and in 74 the last census of Roman citizens ever made was taken. In 79 a conspiracy formed by Alienus Cæcina and Marcellus was discovered, and the former was summarily put to death, while Marcellus committed suicide. In the summer of the same year Vespasian on account of failing health retired to his early home in the Sabine country. He was one of the best and wisest of the Roman emperors, although his personal character was disfigured by certain mean traits, the most conspicuous of which was avarice. His simple style of living furnished a strong contrast to the luxury and debauchery of his immediate predecessors. The two succeeding emperors were his sons Titus and Domitian.

VESPERS (Lat. *vesper*, evening), in the Roman Catholic church, a portion of the divine office recited daily by priests, and generally sung publicly, as the afternoon service, on Sundays and other high festivals. It consists of five of the psalms of David, a hymn, the *Magnificat*, or canticle of the Virgin Mary, from the 1st chapter of St. Luke, and several prayers, anthems, &c.

VESPUCCI, Amerigo, an Italian navigator from whom the name of America is derived, born in Florence, March 9, 1451, died in Seville, Feb. 22, 1512. He was in business in Seville as an agent of the Medici family when Columbus returned from his first voyage; and in 1496, while fitting out four caravels for the Spanish service in the countries lately discovered, he occasionally met with Columbus, and was induced to prepare for a career of nautical adventure. In 1499 he sailed from Spain in an expedition under Ojeda which visited the neighborhood of Cape Paria and several hundred miles of coast, and returned in June, 1500. In July Vespucci wrote to one of the Medici of Florence an account of the voyage, which lay hid in manuscript till 1745, when it was published by Bandini. In May, 1501, he entered the service of Emanuel, king of Portugal, and participated in an expedition which visited the coast of Brazil. Of this voyage he also wrote an account to the same member of the Medici family, which was first brought to light by Bartolozzi in 1789. In 1504 he sent to the same person a fuller narrative of this expedition, which was published at Strasburg in 1505, under the title, *Americus Vesputius de Ora Antarctica per Regem Portugallie pridem inventa*. From this voyage he acquired the reputation of being the discoverer of the mainland. In May, 1503, he commanded a caraval in a squadron that sailed for the discovery of Malacca, but parted company from the rest, and finally made his way to the coast of Brazil, where he discovered the bay of All Saints, remained there two months, then ran 260 leagues further S., where he built a fort, took in a cargo of Brazil wood, and after a stay of five months stood for Lisbon, which he reached in June, 1504. Early in 1505 he sought employment from the Spanish court, and received from King Ferdinand letters of naturalization. Before March 22, 1508, he became pilot major with a salary of 70,000 maravedis. He was placed over a *depósito hydrográfico*, and was charged with the preparation for the *casa de contratacion* of a general description of coasts and accounts of expeditions, in which every year new discoveries were to be entered, besides the construction of charts, the examination of pilots, and other duties. After his return from his

Brazil expedition in 1504, he wrote from Lisbon a letter to René, duke of Lorraine, containing an account of four voyages to the new world, wherein he says that the first expedition in which he was concerned sailed from Cadiz May 20, 1497, and returned in October, 1498. This remark has been the source of a fierce controversy as to the first discovery of the mainland of America, and as to the true character of Vespucci, against whom it has been charged that after the return from his first voyage to Brazil he made a maritime chart, in which he gave his name to that part of the mainland. The statement in the letter is unquestionably false. The name Americi Terra was applied to this continent as early as 1507, by Waldsee-Müller (Martinus Hylacomylus), a geographer of Freiburg in Breisgau, in a small work entitled *Cosmographiæ Introductio, . . . insuper quatuor Americi Vespucci Navigationes.* It does not appear that Vespucci himself had any intention of taking the honor of the discovery from Columbus, with whom he was on friendly terms; and it was not until the appearance of the *Opusculum Geographicum* of Schoner in 1533, and of the attack of Servetus in the Lyons edition of Ptolemy in 1535, that charges were brought against him. —See "Life and Voyages of Americus Vespucius," by C. E. Lester (New York, 1846), and "Vespucius and his Voyages," by Santarem, translated by E. V. Childe (Boston, 1850).

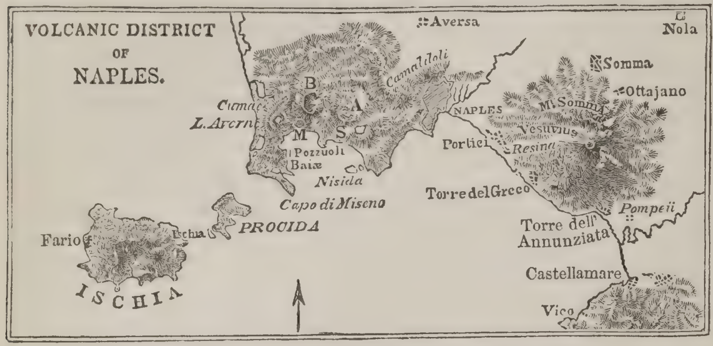
VESTA, the Roman name of the goddess of the home or hearth, identical with the Greek Hestia. According to the Hesiodic theogony, she was the daughter of Cronos (Saturn) and Rhea. Her brother Jupiter permitted her to assume a vow of perpetual celibacy, and granted her the first oblations in all sacrifices. She was not represented by any statue in the temple devoted to her honor, but by the symbolic fire which was kept perpetually burning on the hearth or altar by the vestals, her virgin priestesses. In art she was represented as a slender virgin of noble aspect, standing or sitting, clad or veiled, and holding a lamp or a sacrificial plate in one hand and a sceptre in the other. From her connection with the domestic hearth, every house was regarded in a certain sense as consecrated to her worship; and in the Roman religion she was connected with the Penates. In Greece her priestesses were widows; in Rome they were maidens, and were denominated vestal virgins. In Rome, on March 1 of every year, the sacred fire and the laurel tree shading her hearth were renewed; on June 9, the festival called *Vestalia* was celebrated; and on June 15 her temple was cleansed and purified.

VESTAL VIRGINS (Lat. *vestales*), the priestesses who served in the temple of Vesta, and guarded the sacred fire. The earliest traditions ascribe their origin to a period before the foundation of Rome, Rhea Sylvia, the mother of Romulus, belonging to their number; but their establishment as a part of the Roman religious worship is usually attributed to Numa Pompilius. He selected four for this office, which number was afterward increased to six. At first they were selected by the king, but during the republic and the empire by the *pontifex maximus.* Originally none but the daughters of freeborn parents could be chosen; but so great was the reluctance of fathers to part with the control of their children, that in the time of Augustus *libertinæ* were also taken. The persons selected were obliged to be from six to ten years of age, without physical blemish; their parents must be residents of Italy who had never pursued any dishonorable profession. Their chief duty was to watch by turns night and day the sacred fire on the altar of Vesta, the extinction of which, whether happening from carelessness or design, was regarded as an omen of terrible evil to the state. They also watched over the Palladium, a small wooden image of Minerva, which according to the myth fell from heaven upon the citadel of Troy, and was carried thence to Greece, and afterward to Rome; upon the preservation of this figure the people believed that the existence of the Roman power depended. The term of service lasted 30 years, the first 10 of which the priestess passed in learning her duties, the next 10 in performing them, and the remaining 10 in instructing others. After that time she might return to the world, and even marry; but the privilege was rarely taken advantage of. The greatest importance was attached to the chastity of a vestal; and when she violated her vow in this respect, she was, according to the law of Numa, stoned to death, but according to the practice from the time of Tarquinius Priscus, she was buried alive in a place called the Campus Sceleratus near the Colline gate. Her paramour was scourged to death in public in the forum. The vestals were supported at the public expense, completely released from the control of their parents, could bear testimony in a court of justice without taking an oath, and could make wills; whenever they went abroad, they were preceded by lictors, and consuls and prætors made way for them, and lowered their fasces; a criminal whom they accidentally met was spared from punishment if they demanded it; and their intercession in behalf of accused persons had great weight. Wills and solemn treaties were intrusted to their care, and conspicuous places were given them at the shows, and by Augustus at the theatres also. The oldest of the vestals was called *vestalis maxima* or *virgo maxima.*

VESTRIS (originally VESTRI), the name of a family of dancers of Italian extraction, who emigrated from Florence to Paris about 1740. **I. Angiolo Maria Gasparo,** born in Florence in November, 1730, died in Paris, June 10, 1809. He made his first appearance in Paris in 1769 at the Italian theatre, in which he performed with great success until his retirement on a pension in 1780. **II. Gaetano Apollino Baldassare,**

brother of the preceding, born in April, 1729, died in Paris, Sept. 27, 1808. His career at the theatre extended from 1749 to 1781, during most of which time he held the posts of ballet master and first dancer. He was popularly known as the "god of dancing," but his talent was executive rather than inventive; and he left little worthy of his reputation, his chief compositions being the ballets of *Endymion* and *Le nid d'oiseaux.* He was exceedingly ignorant and vain. "There are but three great men in Europe," he once observed, "the king of Prussia, M. Voltaire, and myself." His vanity was so original and amusing as to offend no one, and rather added to his reputation. In other respects he was a man of great honesty and amiability. **III. Marie Auguste,** called Vestris-Allard, or Vestris II., natural son of the preceding, born in Paris, March 27, 1760, died there, Dec. 6, 1842. He made his début in 1772, and from 1780 to 1816 was first dancer at the opera. He appeared for the last time at the age of 75, at a benefit given to Mme. Taglioni, and won great applause. Though inferior in dignity to his father, he surpassed him in strength and agility. He retired from the stage in 1819, and was professor in the conservatory till 1828. **IV. Auguste Armand,** son of the preceding, made his début in 1800 in a ballet in which his father and grandfather also took part. He had a great reputation throughout Europe. **V. Madame** (Bartolozzi), wife of the preceding, born in London in 1797, died Aug. 9, 1856. She was the granddaughter of Bartolozzi the engraver, was married in 1813, and in 1815 made her first appearance upon the Italian stage as Proserpina in the opera of that name. Subsequently she became one of the most popular English actresses of the day, particularly in male parts which admitted of a display of her figure. She excelled in ballad music, in which her voice, a sweet and powerful contralto, appeared to great advantage. Late in life she married Charles Mathews the younger, but retained her former name, and had the management successively of several London theatres.

VESUVIUS, a volcano of southern Italy, on the E. shore of the bay of Naples, 8 m. E. S. E. of the city. It is the eastern extremity and the principal vent of a chain of volcanoes extending from it through the Phlegræan fields to the islands of Procida and Ischia. Before the Christian era Ischia seems to have been the principal scene of volcanic disturbance in this district, and we have no record of any eruption of Vesuvius previous to that of A. D. 79, by which Pompeii and Herculaneum were destroyed. It is frequently mentioned by the older writers without reference to its volcanic character, but Strabo inferred from its structure that it had been a volcano, and Diodorus Siculus says it had "many signs of having been burning in ancient times." Viewed from Naples, Vesuvius appears to have two peaks, which are called respectively Somma and Vesuvius. But the ancient mountain, according to Strabo, had but one, a truncated cone with an even outline; and it is to be inferred from Plutarch that it had a crater with steep cliffs, the interior of which was overgrown with wild vines. The flanks of the mountain were covered with cultivated fields, and on the bay at its foot were Pompeii and Herculaneum. The site of the latter is now occupied by the village of Resina. It is supposed that the walls of this ancient cone were destroyed in the eruption of 79, when the present cone was formed. In this eruption only scoriæ and ashes were ejected, and there is no well authenticated record of a flow of lava from the mountain before 1036, when the lava is said to have reached the sea, although eruptions had taken place in 203, 472, 512, 685, and 993. In the eruption of 472 the ashes were carried as far as Constantinople, and in that of 512 to Tripoli. Other eruptions occurred in 1049, 1138 or 1139, and 1306, during the last of which terrible earthquakes shook the surrounding country, and destroyed Isernia and Brindisi and many thousand lives. In 1198 Solfatara was in eruption, and in 1302 Ischia, both discharging lava. With the exception of a slight eruption in 1500, Vesuvius was quiet till 1631; but during this period Etna was unusually active, and in 1538 (Sept. 29 and 30) a volcanic cone, now called Monte Nuovo, was raised in the bay of Baiæ 440 ft. high, covering an area 8,000 ft. in circumference. During the 131 years preceding the eruption of 1631 the sides of the crater became overgrown with trees and shrubs, below which was a plain where cattle were pastured. The eruption, which began in December, 1631, and lasted till February, 1632, was accompanied with many streams of lava and torrents of boiling water, which overflowed the towns at its base and destroyed many thousand lives. After this eruption the cone was 1,530 ft. lower than that of Somma, although it had previously been higher. During the last century the eruptions increased in frequency. That of 1779 is described by Sir William Hamilton as among the grandest of these phenomena. White smoke like heaps of cotton rose four times as high as the mountain, and spread about it to a proportional extent. Into these clouds stones, scoriæ, and ashes were projected at least 10,000 ft. high. On subsequent days columns of fire shot forth three times as high as the mountain, and large masses of rock were thrown out, one of which was 108 ft. in circumference. The eruption of June, 1794, destroyed the town of Torre del Greco by a stream of lava estimated by Breislak to contain more than 46,000,000 cubic feet, which flowed into the sea in a mass 1,204 ft. wide and 15 ft. high. Eruptions have occurred during the present century in 1804, 1805, 1809, 1812, 1813, 1817, 1820, 1822, 1828, 1831, 1834, 1838, 1841, 1845, 1847, 1849, 1850, 1855, 1858, 1861, 1865, 1868, and 1872. That of 1822 broke up the whole top of the mountain, and formed



A. Astroni. B. Monte Barbaro. M. Monte Nuovo. S. Solfatara.

an elliptical chasm about 3 m. in circumference, and supposed to be 2,000 ft. deep. In May, 1855, floods of lava descended as far as the village of Cercolo, committing great ravages in the cultivated fields. In May, 1858, an overflow of lava almost enveloped the hill on which stands the Hermitage. The eruption of December, 1861, was very violent. Eleven cones opened about ½ m. from Torre del Greco, from one of which flowed a stream of lava which threatened the town. Crevices opened in the streets, and many houses were shattered. In March, 1865, the mountain was also in eruption, and again in December, 1867, continuing until the summer of 1868, when the cone attained an elevation of 4,253 ft. above the sea. On April 24, 1872, a great flow of lava succeeded an unusual outpouring of smoke and flame which had lasted for several months. A large tract of cultivated land was desolated, the villages of San Sebastiano and Massa were destroyed, and many lives lost. The streets of Naples were filled several inches deep with fine black sand. In December, 1875, the mountain again showed signs of activity, and in February, 1876, the disturbances of the instruments in the observatory indicated a speedy eruption, which began in the latter part of March.—Vesuvius stands alone on the plain of Campania, on a base about 30 m. in circumference. The ascent from the bay on the W. side is by a gradual slope for about 3 m. to the base of the cone, where it attains a height of 2,300 ft. above the sea. Surrounding the cone on the N. and E. sides is the semicircular escarpment of Monte Somma, the ancient cone, with precipitous walls on the inside and sloping gradually on the exterior to the plain below. On the S. side also of the cone is a terrace-like projection called the Pedamentina, supposed to be the continuation of Somma. The valley between Somma and the base of the cone is the Atrio del Cavallo, so called because horses are left there by those about to ascend to the summit. The cone rises at an angle of 25° to 40° to an additional height of 1,600 to 1,900 ft., varying greatly after eruptions. After that of 1845 its height above the sea was 3,876 ft., and after that of 1868 4,253 ft., the highest elevation ever reached up to that time. The top of the cone is truncated, the diameter being about 2,000 ft. The interior of the cone, or crater, slopes gradually to a depth of about 500 ft., which also varies greatly after eruptions. The lower strata of Somma are formed of compact tufa, composed of pumice and ashes, interspersed with fragments of limestone. Upon these lie beds of leucitic lava alternating with beds of scoriæ, and intersected by dikes of compact lava. The cone of Vesuvius is composed of concentric layers of lava, scoriæ, and sand, distributed around it with much regularity. According to Lyell, a greater variety of simple minerals are found in an area of three square miles around it than in any other place of the same dimensions on the globe. Prof. Scacchi has reduced the number, once said to be nearly 400, to about 40 species, most of which are found in the ancient lavas of Somma. A meteorological observatory has been established since 1844 on an elevation near the Hermitage, 2,080 ft. above the sea, which contains besides meteorological apparatus delicate instruments for indicating earthquakes. It is now under the direction of Prof. Palmieri. In 1875 the construction of a railway from Naples to the summit of the mountain, over a line about 16 m. long, was begun. Ordinary locomotives are to be used for 14 m., and a stationary engine and endless rope for the remainder of the way. The last division is in two sections, the first of 2,300 yards extending to the Atrio del Cavallo, where the drawing machine and the necessary buildings will be placed, and the other of 1,200 yards ending a few steps from the crater. The station in the Atrio del Cavallo will be 21 ft. under the lava, and the rails are so guarded that the current of lava in case of an eruption will be turned from them.—The wine called Lachrymæ Christi is produced on the slopes of Vesuvius, where also are most of the market gardens which supply Naples with vegetables.—See Schmidt, *Vulcanstudien* (Leipsic, 1874); Palmieri, *Cronaca del Vesuvio* (Naples, 1874); and Phillips, "Vesuvius" (London, 1874).

VESZPRÉM (Ger. *Wesprim*), a S. W. county of Hungary, partly covered by the Bakony range, and at the southeast bordering on Lake Balaton; area, 1,609 sq. m.; pop. in 1870, 201,434, mostly Magyars. The surface is mountainous or hilly, and the soil productive; good pastures for cattle, sheep, and swine abound.

The rivers are insignificant. The capital, Veszprém, is situated near the N. extremity of Lake Balaton, 60 m. S. W. of Buda; pop. in 1870, 12,002. It has a fine cathedral and episcopal palace, a Piarist college, a gymnasium, and considerable trade.

VETCH, or **Tares,** the name of plants of the genus *vicia*, which is the ancient Latin name. The genus, which belongs to the *leguminosæ*, is closely related to the pea and lentil, from the first of which it differs mainly in the more numerous leaflets and the character of the style, and from the other in the shape of the seeds. There are several native and introduced species in this country. The vetch of agriculture is *V. sativa*, which has been so widely disseminated by cultivation that its native country is not known, but is supposed to be southern Europe. In cultivation it is annual or biennial, according to the time of sowing; the stems are 1 to 2 ft. long; the leaves have 8 to 14 leaflets, varying in shape from linear to obovate, notched and furnished with a point at apex, the terminal leaflet replaced by a tendril; the purple flowers are sessile, solitary, or in pairs, and succeeded by a narrow pod 1 to 2 in. long, with 10 to 12 globular seeds. The vetch is much cultivated in Europe as a fodder plant, the fondness of animals for its herbage being sustained by its analysis, which shows it to be quite the equal of clover in nutritive principles. The seeds are a favorite food with poultry and pigeons, and are sometimes used as human food; but they are very indigestible. Winter and spring tares are merely strains produced by the time of sowing; if sown in late summer or early autumn, the crop is harvested the next year; if in spring, it is cut the same year. The vetch has never become popular with American farmers, and it is but rarely cultivated.

Vetch (Vicia sativa).

VETERINARY SCIENCE (Lat. *veterinarius*, pertaining to domestic animals). Veterinary medicine was studied among the ancient Egyptians, Arabs, Parsees, and Hindoos, and it attracted considerable attention among the ancient Greeks. Hippocrates and Aristotle describe maladies of the domestic animals, and 600 years later we find systematic Greek works on veterinary medicine. The science was virtually lost in the destruction of the eastern empire, and only began to revive in the end of the 16th century, when Carlo Ruini published his work on the anatomy of the horse. But little real progress was made till 1762, when the prevailing epizoötics among farm animals led to the establishment of the Lyons veterinary college, speedily followed by the founding of similar institutions in every country of Europe. In the 19th century especially the earnest study of comparative anatomy and physiology, and the careful investigation of animal diseases, and of the contagions and parasites which are intercommunicable among the lower animals and between them and man, have opened up a new path of usefulness for veterinary medicine, advanced the science of comparative pathology, and added a most valuable chapter to the doctrine of prophylaxis. As at present existing, veterinary science embraces the anatomy, physiology, hygiene, dietetics, and general care of domestic animals, together with their diseases, therapeutics, and prophylaxis, the philosophy of breeding, shoeing, sanitary principles of building, drainage, and ventilation, the influence of soils and seasons on the food, water, and air, the effects of climate on the animal economy, the laws of contagion, the development and metamorphoses of parasites, &c. I. EPIZOOTIC INFLUENZA. This is a specific typhous fever, occurring epizoötically and complicated with inflammation of the mucous membrane lining the air passages, or less frequently of the lungs, pleuræ, pericardium, liver, bowels, muscles, or joints. It is described as seen in horses, A. D. 330, by the Greek veterinarian Absyrtus, and in the course of the last two centuries has occurred simultaneously in man and horse no less than 20 times. Less frequently it has attacked other animals as well, particularly dogs and cats, while in the great majority of cases it has confined its ravages to a single genus. It was formerly thought to fall on a whole continent or country instantaneously, but a careful study of its outbreaks generally discloses a steady advance over a continent for a period of months or even a year. The American epizoötic of 1872 advanced from place to place with a rapidity varying according to the celerity of communication, extending along the lines of railroad, and attacking first the large cities, later the smaller ones, and finally the villages and isolated farms, and frequently pursuing a retrograde course from the cities and railroads into the adjacent country. The whole country finally suffered, excepting such places as were protected against the introduction of strange horses. Thus La Paz was saved by the gulf of California, Vancouver island by a rigid exclusion of horses and mules, Prince Edward island from its being unapproachable by reason of ice, and Key West, Hayti, and Jamaica by their insular position, while Cuba suffered because of imported American horses. The disease was finally arrested at Panama, where the state of the country forbids the use of horses. It reached the Pacific coast not at San Francisco, but at Santa Barbara by the line of stages from the mining regions of Nevada. It took nine months to travel from Toronto to British Columbia, and eleven to reach San Salvador. Nothing but contagion will account for the manner in which the epizoötic spread, though a considerable latitude must be allowed for the conveyance of the germs through the atmosphere. The alleged propagation by ozone is incompatible with its severity in cities, where this agent is usually absent. The origin of the epizoötic is very obscure. The only peculiarity of the month preceding the outbreak at Toronto was an unusual number of thunder storms.—Incubation extends from one to three days. The attack is usually remarkably sudden; hence the names *Blitzkatarrh*, *la grippe*, &c. A horse which half an hour before seemed in robust health may suddenly droop his head, ears, and lips, partially close his eyes, and stand with one or two legs semi-flexed to find relief from his weariness. He maintains one position, or moves unsteadily and reluctantly with arched back and cracking joints. The hair is erect, the skin tender, the nose and extremities cold, and there may be trembling or even nervous jerking. Sometimes the prostration is much less marked, and a cough may be the main or only symptom for a time. It is dry, husky, and frequent, attended with accelerated breathing, increased temperature of the body, hot clammy mouth, rapid compressible pulse, scanty high-colored urine, and hard mucus-covered dung. The membranes of the nose and eye are reddened, often with a tinge of brown or yellow (pinkeye); and the ear placed over the lower end of the windpipe detects an unusually loud blowing murmur. In slight cases a watery discharge from the nose changes into a white muco-purulent one, the cough becomes loose and easy, fever subsides, and recovery ensues. More frequently, toward the third or fifth day the cough becomes deep, painful, and paroxysmal, pulse and temperature rise, appetite becomes fastidious, eyes swollen, red, and watery, nose livid, with spots or patches of brown or yellow or of blood-staining; swallowing is painful, water being returned through the nose, and the throat tender to the touch. The chest is involved, and if the lungs are implicated there is a want of resonance on percussion over the affected part, and a fine crepitation when the ear is applied; if the pleuræ suffer, there is extreme tenderness when that part of the chest is touched, and a low rubbing sound, which soon gives place to silence and dulness of percussion up to a certain level. If the abdominal organs are attacked, there is great torpor and stupor, tense tender belly, with dusky mucous membranes, and yellow, brown, or red urine, with small weak pulse, quick catching breathing, weak painful cough, and costive bowels, one or two balls being passed rather frequently but with much straining and coated with mucus. In fatal cases prostration becomes extreme, breath fetid, anus puffy and relaxed, dung soft, bloody, and slimy, pulse imperceptible, eyes sunken, limbs deathly cold, and debility extreme. Rheumatism, dropsy, paralysis, and inflammation of the eyes are occasional complications. In the treatment a warm, airy box, comfortable clothing, and laxative and easily digested food are essential. Relieve costiveness by copious injections of warm water or two or three drachms of aloes, and follow up with mild febrifuge diuretics (liquor of acetate of ammonia 3 oz., extract of belladonna 1 dr.), repeated twice daily. In case of severe sore throat, mix the belladonna with chlorate of potash, vinegar, and honey, and smear on the back teeth, to be swallowed at leisure. In extreme prostration, or after the fever subsides, use stimulants (aromatic ammonia, carbonate of ammonia) and tonics (tincture of gentian). The inflamed region may be fomented, wrapped in warm sheepskins, or rubbed with a mixture in equal parts of strong ammonia and olive oil. If the bowels are involved, give a mild laxative (olive oil, ½ to 1 pt.), with mucilaginous drinks and anodynes (opium ½), the last two being continued twice a day. The other complications must be met as they appear, and according to their indications. II. STRANGLES, or DISTEMPER. This is a fever of solipeds, attended with nasal catarrh and swelling and abscess between the bones of the lower jaw, or less frequently in groups of lymphatic glands elsewhere, or in some internal organ (lungs, kidneys, brain, &c.). It especially attacks the young, though no age is exempt, and is largely precipitated by change of feeding, work, heats and chills, hot impure stables, emigration to a new locality and climate, and other results of domestication. The irritation attendant on teething and shedding the coat is not to be forgotten. Contagion is a further cause. Second attacks are unusual unless the subject has been removed into a new district in the interval. The disease usually sets in slowly, the animal appearing to be thriving badly for a time, and losing his accustomed energy. Then a cough sets in, with redness of the nasal mucous membrane, watery discharge from nose and eyes, slavering, fever, costiveness, scanty, high-colored urine, and thirst. Then a uniformly smooth, hot, painful swelling rises between the branches of the lower jaw, or beneath the ear, gradually softens in the centre, and bursts, discharging a white creamlike matter. The nasal discharge has meanwhile become thick, white, and abundant, and swallowing and even breathing may be difficult until the abscess bursts. The rupture of the abscess is the signal for improvement, the sac gradually contracts and heals out, the general health is restored, and the animal thrives better than before the illness. In treatment the aim must be to support the strength, and favor the formation of matter between the jaws. Feed liberally on boiled oats or barley or warm bran mashes, to be eaten from a nose bag, and poultice or assiduously foment the swelling until nearly ready to burst, when it may be opened with a lancet, and the fomentations continued at intervals. Medicine is rarely wanted. When the matter forms in unwonted situations the treatment will not differ, and the danger to life will depend on the importance of the parts involved. (See also BOTS, and GLANDERS.) III. DISEASES OF BONES. Some of the most important maladies of the horse originate in inflammation of bony tissue. As types the familiar bone spavins, splints, and ringbones may be referred to. All are alike due to some injury of the bone or of its fibro-vascular covering, causing exudation of lymph from the vessels and the hardening of this lymph by the deposition of earthy salts. All bone is permeated by minute blood vessels, around which and between the concentric bony plates are rows of microscopic particles of soft animal matter (nuclei), which preside over the nutrition of the part. The vessels are mainly derived from the fibrous membrane investing the bone. When inflamed these vessels throw out lymph, but most abundantly on the surface, where swelling can take place most readily, and this, raising the fibrous covering, drags out the vessels and nuclei somewhat from the bony canals, so that when these latter resume their normal functions they transform the lymph into a bony material. This is the explanation of the development of most of these bony swellings. Where sinews are attached to bones, undue traction upon them tends equally to draw out the vessels and nuclei from the surface and to build up new bony tissue, while earthy salts are at the same time deposited in the substance of the tendon to some distance from the attached end.—*Spavins* are bony deposits on the antero-internal aspect of the lower part of the hock joint, where the great strain and compression come in rapid paces and in heavy draught. The joint is here provided with an extra tier of bones and two additional layers of elastic cartilage to ward off injury; but too often these prove insufficient; the nutrition in the small bones and on their surfaces is deranged; lymph is exuded, and finally consolidates two or more of the small bones into one solid mass, and abolishes the slight gliding movements and resiliency naturally resident in the joints between them. Then if the inflammation is allowed to subside, the new structure becomes firmly consolidated, and lameness disappears. Spavins occur mainly in joints that are narrow at their lower part, alike when viewed from before backward and from side to side, in overworked young horses, and in such as suffer from impaired health, faulty nutrition, or rheumatic taint. The swelling is generally best seen by standing about two feet to one side of the shoulder and looking across the lower part of the inner side of the joint. It should also be compared with that of the opposite limb, examining with eye and hand. The sudden catching up of the limb, or the imperfect bending of it in progression, the stiff awkward movement in turning, and the improvement in most cases after the animal has been driven for some distance, are familiar to every horseman. In the early stages of spavin with heat and tenderness, soothing measures should be adopted to subdue inflammation and check deposit, thereby obviating the danger of fixing the joint. Hot fomentations, cold wet bandages, or astringent and arnica lotions, with a dose of physic and rest, are often sufficient, though if lameness is very great a high-heeled shoe will keep the joint easier. Later, when local inflammation has greatly moderated, active blistering and rest may remove the remaining irritation and secure consolidation of the exudate. As a blister, Spanish flies or iodide of mercury (one part to four of lard) will usually serve a good purpose. When there is little or no external swelling or tenderness, but ulceration of the opposing surfaces of the small bones in the interior of the joint, nothing succeeds so well as firing followed by a long rest.—*Splints* have a similar origin with spavins, but appear on the inner side of the shank bones of the fore limbs, as being nearest the centre of gravity, and the point where concussion especially tells. They usually begin on the inner splint bone, which extends from the knee down for about three fourths of the length of the canon. Inflammation is set up, and the resulting exudate becoming ossified usually binds the two bones together and remains as a permanent enlargement, but without inducing lameness after it is consolidated throughout. But if the animal is kept at work, renewed injury is inevitable; the structures being now soft, irritable, and susceptible, new layers of lymph continue to be exuded and consolidated into bone, and thus a splint, like a spavin, may increase to almost any size. While thus growing lameness is almost necessarily present, and is greatly aggravated by trotting on hard ground, whereas it may not be shown at all on a soft surface. By standing in front of the patient, the enlargement on the inner side of the limb is easily seen, and by passing the finger or thumb down the slight groove between the shank bone and the splint, it is distinctly felt. It is usually warm and tender. Splints are treated exactly like spavins, by rest and soothing applications in the early stages, followed by blisters and even firing. In both the recent deposit which is still soft may be largely removed, but old standing bony enlargements are permanent. In each the lameness is often greatly aggravated by the tension of the fibrous membrane over a rapidly growing swelling, and in spavin by the increased strain thrown on a sinew which passes over the seat of enlargement; in such cases a skilful division of these structures with a narrow-bladed knife, which will make little more than a puncture in the skin, is followed by the best results.—*Ringbones*, which appear as hard swellings on the bones between the fetlock and hoof, generally take their origin at points where the lateral ligaments of the joints are attached, though they may arise from concussion and injury to the front as well. In these, as in splints and spavins, the inflammation may subside, the exudate harden into bone, and all lameness disappear, so that the swelling remains only as an eyesore and not a real injury. But from the constant strain on the lateral ligaments, when standing as well as at work, the inflammation is far more likely to be kept up, and the enlargement to go on increasing, making ringbones more dangerous than splints or spavins. Again, if they extend over the joints, as they often do, they give rise to a permanent stiffness and lameness, by abolishing the considerable movements normally effected in these. The treatment of ringbones is therefore far less satisfactory than that of splints and spavins. It proceeds on the same principle, first by soothing and antiphlogistic applications when inflammation is acute, and later by blistering or firing when its severity is somewhat moderated. The counter irritation must usually be more severe and repeated than in the other affections, and deep firing in points must often be resorted to.—Any of the above named forms of bone disease may be primarily dependent on a constitutional infirmity with impaired nutrition of the skeleton, and in such cases an improvement of digestion and general tone must first be secured. Such general infirmity is usually betrayed by the coexistence of several such causes of unsoundness in the same animal (splints, spavins, ringbones, navicular disease, sprains, &c.), by the passage of an excess of earthy salts (phosphates) in the urine, and by a general lack of energy and endurance. IV. SHOEING AND DISEASES OF THE FEET. A great majority of diseases of the feet take their origin in faulty modes of shoeing. The hoof is made up of horny tubules, all excepting some of those of the frog running from above downward and forward. Near the quick these are wide and open, filled with liquid, and surrounded by a soft, moist, horny substance; but in approaching the surface they become finer, closer, and encircled by horn of almost flinty hardness. The tubes of the hoof wall extend from the coronet to the lower wearing border, where they are closed by attrition. Those of the sole are covered by thick horny scales or flakes, with a fine powder between them and the tough elastic horn, and effectually protecting the latter from desiccation and mechanical injury. In the healthy state therefore the whole hoof is well provided against evaporation, drying, and shrinking. But the case is altered when the tubes of the hoof wall are laid open with the rasp, and those of the sole and frog with knife and buttress. Then the moisture is rapidly exhaled, the horn dries and shrinks, the heels curl inward, and the sole becomes more arched, drawing in the lower border of the hoof wall. The sensitive parts beneath are absorbed under the pressure, and distortion and weakness are inevitable results, even if active disease is for a time escaped. A free use of hoof ointments will to some extent obviate the evil, though they make but a poor substitute for nature's admirable protection. The preservation and preparation of the foot is of far more consequence than the form of shoe. The hoof should be interfered with as little as possible, save where the shoe is to rest. This part should be pared or rasped until the elastic horn is reached, and so as to leave a smooth bearing surface, extending on the sole to a distance of perhaps half the thickness of the hoof wall. The two sides, inner and outer, should be of uniform height at all corresponding points, and the heel and toe left of an elevation according with the natural form of the particular foot. Usually the cutting must be almost entirely confined to the toe. While avoiding the paring of the tough elastic horn of the heel, we must equally avoid leaving hard thick flakes of dead horn, which can only act as foreign bodies and bruise the part. The outer edge of the hoof wall may be slightly rounded with a file, to obviate splitting. The foot having thus been prepared with corresponding height on both sides, and in a way to prevent any distortion of the bones and joints of the limb from their natural direction, the next point is to adapt the shoe to the wearing surface. The upper surface of the shoe should be perfectly level, unless a very gentle curve is given from heel to toe, and the bearing on the hoof should be uniform throughout, as unequal pressure will tell sooner or later on the foot, or on the bones and joints above. Fitting the shoe at a dull red heat is hurtful to the horn, but of two evils it is preferable to unequal bearing. For perfect fit it is better to have the shoe coarsely fullered, and to drive the nails rather low as tending to injure less horn, and the hold taken should be gradually less in approaching the heel, especially on the inner side. The nails should be drawn up so as to hold the shoe firm, but no more; and in riveting, the transverse groove usually made with the rasp should be avoided, though a slight notch may be made with the knife beneath each nail, to receive the clench. In filing off any roughness of the clinches, avoid touching the hoof. Finally, remove the shoe before the hoof grows over it, and especially before the growth of the toe has drawn it forward so that it sets in on the heels.—*Navicular Disease.* This is a disease of a small bone situated beneath the coffin joint, and serving as a pulley over which plays the flexor tendon of the foot. This tendon and its synovial sheath also participate in the disease. These structures lie directly above the anterior part or body of the horny frog, which thus serves as a protecting cushion or pad. Besides the general faults of nutrition predisposing to bone disease, rheumatism, hard work, faulty shoeing, and neglect of or injury to the feet contribute to its development. It is particularly liable to complicate injuries of the heel, the inflammation extending by proximity to the bursa of the flexor tendon and the navicular bone. Hence rapid paces and the system of shoeing are largely chargeable with the disease. In France, where the shoeing generally is good and protective, the affection is comparatively rare; in England the rapid paces and the systematic weakening of the feet in shoeing render it exceedingly prevalent; but in America, through the fondness for trotting, poor shoeing, and rough, uneven roads, there are incomparably more cases than in either. The continued idleness of horses during our rigorous winters, broken by occasional fast drives, and the general disorder caused by an overfeed of grain, or a drink of iced water when hot and exhausted, are not to be overlooked. The affected foot may be pointed eight or ten inches in front of the other, with the heel slightly raised, for months before actual lameness appears. The horse steps short, stumblingly, and on the toe when first brought out, but the lameness diminishes or disappears after he has gone a mile or two. It is worse again when cooled down after a long or hard drive. It may also appear at work as an occasional stumble, or a temporary dropping on the sound foot. The shoe is worn at the toe, and the foot is warm at its posterior part, and steadily shrinks so as to be visibly smaller than its fellow. There is flinching when the sole is tapped with a hammer on each side of the body of the frog or on the wall in the region of the quarter. The same results from pressure of the thumb over the flexor tendon, behind the pastern, as far down as can be reached in the hollow of the heel. The wasting of the muscles of the limb and shoulder from disuse deludes many with the idea that the lesion is resident there. Treatment is not often satisfactory, except in recent cases. To soothe inflammation, give a dose of physic, remove the shoe, shorten the toe, leaving the heel of its full height, keep the horse standing throughout the day in cold water or a puddle of wet clay reaching to the top of the hoof, and apply a mild blister to the front and sides of the pastern, repeating it when the scab from the first has come off. Obstinate cases will sometimes recover under the action of frog setons and a long run in a wet pasture, while for those that are otherwise useless the sensitive nerves going to the foot may be divided, when all pain and lameness will cease. But this is only advisable in chronic cases, when the best system of shoeing can be secured, when the feet can be cleaned and examined on each return from work, and when they can be kept covered with wet swabs while standing indoors.—*Founder* is an inflammation of the secreting structures of the foot, but especially of the laminæ which connect the hoof wall with the sensitive parts anteriorly. It results from direct injury, as over-exertion on hard roads, blows, bruises, freezing, pricks or binding with nails, unequal pressure of the shoe on different points, or the long strain on the feet during a sea voyage; or it may result from a sudden chill, a drink of cold water when heated and fatigued, an overfeed of grain, especially if new or only partially ripened, an overdose of purgative medicine, or as a sequel of disease of the lungs or other internal organ. When not caused by direct injury to the foot, it is usually introduced by fever, staring coat, or shivering and general stiffness and soreness, without at first any great tenderness of the feet. Soon the disease concentrates itself in the anterior part of the fore feet (rarely the hind), and the patient leans back, rests on his heels, and brings his hind feet forward to bear as much weight as possible. If urged to move, he sways back, dragging the fore feet on the heels, or lifts both at once and comes down on the heels only. The feet are hot and extremely tender to the hammer or pincers, and the patient resists all efforts to lift them. The pulse is rapid and hard, the breathing hurried, and the skin often perspiring. In the mild forms there is less fever and local suffering, but in all cases the walking on the heels and the heat and tenderness of the feet are characteristic. The preliminary stage of general stiffness may often be cut short by a free perspiration induced by wrapping in a blanket wrung out of hot water and closely covered by several dry ones, or by heavy dry clothing and full doses of aconite, lobelia, or tobacco. Others attain the same end by walking the patient, barefoot or with broad-webbed bar shoes, on a newly ploughed field. But if some inflammation has set in, the feet must be unshod, and enveloped in large, soft, warm poultices; a laxative should be given if the bowels are not too irritable, followed by sedatives and cooling diuretics, and the patient coaxed or even compelled to lie down. When nearly well, a slight blister round the coronet, and a moist clay paddock, or hoof ointments, may perfect the cure.—*Corns* are common as simple bruises of the heel (usually the inner), often resulting in high strong heels, from accumulation of dry hard flakes of horn when the shoes have been left on too long; in weak ones from undue paring of the sole between the wall and the bars; and in all from the pressure of stones or hardened earth or clay, or the setting in of the shoe when drawn too far forward by the growth of the toe. If of old standing, there is often a horny swelling in the seat of the bruise, pressing inward on the quick. Other results are distortion of the heels of the coffin bone, ossification of the lateral cartilages which prolong that bone posteriorly, navicular disease, and the formation of matter which tends to burrow in different directions, forming fistulæ and causing extensive destruction of the soft parts. Corns cause marked lameness, pointing of the foot, with slight elevation of the heel, and a short, stilty, stumbling gait. Testing the affected heel with pincers or hammer elicits signs of tenderness, and the horny sole in the angle of the heel is marked with red points and patches, from extravasated blood. If matter has formed, the patient will often hesitate to touch the ground even with the toe, and soon there is swelling and tenderness at the coronet where the pus is about to escape. Should the injury not exceed a simple bruise, it may be allowed to grow out. A bar shoe may be applied so as to rest on the frog, and remove the pressure from the diseased heel, while the patient is allowed to stand in water, or with wet swabs and linseed stuffing for the sole, until inflammation subsides. The shoe must be removed before it settles down, and reapplied so as to protect the heel as before. If matter has formed, pare down the sole until it escapes, remove all horn detached from the quick, thin the edges of the adjacent horn, apply a poultice for a few days, then apply a bar shoe with leather sole over an abundant stuffing of tar and tow. In low weak heels with extensive disease of the posterior part of the coffin bone, and above all with ossification of the lateral cartilages, the recurrence of corns can hardly be prevented, although careful shoeing with bar shoes, resting very lightly on the heels, will do much to mitigate their severity.

V. BREAKING AND TRAINING OF HORSES. In careful hands the colt should be led and handled while still with his dam, but should not be made a general pet and plaything. Many of the most incorrigible horses have been pets as foals, and learned at this early age to retaliate in their play. To halter a colt, he should be driven into a narrow place in stable or yard between two old steady horses, that will virtually hold him until the halter or bridle has been got on. All sudden movements are to be avoided.—*Training* to bring a horse into condition for hard work consists in the removal of all superfluous fat, and the development and hardening of the muscles. The best condition is not to be attained by a training of a few weeks or months, and trotters rarely reach their highest speed until years after they are matured. The colt intended for this training should be fed on grain from the time he leaves his dam, and should have free scope for exercise and development. The final treatment is by sweating, physic, and graduated exercise. Sweating is employed mainly to get rid of superfluous fat, and may be secured by active exertion, by clothing, or by the Turkish bath. The duration and frequency of the sweats must vary with the subject, but the liquid should always be scraped off, and the horse rubbed dry, and walked out in light clothing until he cools. A dose of physic is useful in reducing fat, counteracting plethora, and cooling the limbs, but is especially beneficial in clearing away irritants and accumulations from the intestines, and improving appetite and digestion. But it is always dangerous in injudicious hands, and should never be repeated unless the state of the limbs or of the general health demands it. Exercise should gradually increase from walking to trotting, and cantering or galloping, according to the development of condition and the use to which the animal is to be put. Feeding must be liberal upon hay and oats, the latter being steadily increased and the former diminished as the more active work is demanded. In perfectly sound horses with clean limbs, brans may be added with good effect.—See Bouley, *Traité de l'organisation du pied du cheval* (Paris, 1851); Bouley and Reynal, *Dictionnaire de médecine vétérinaire* (vols. i.–x., Paris, 1856–'73); Rey, *Traité de maréchalerie vétérinaire* (Paris, 1865); Chauveau, *Traité d'anatomie des animaux domestiques* (Paris, 1871; translated into English by George Fleming, "Comparative Anatomy of the Domesticated Animals," London and New York, 1873); Colin, *Physiologie comparée des animaux* (Paris, 1871); Saint-Cyr, *Traité d'obstétrique vétérinaire* (Paris, 1874); Tabourin, *Matière médicale* (Paris, 1875); Hering, *Handbuch der thierärzlichen Operationslehre* (Stuttgart, 1866); Röll, *Lehrbuch der Pathologie und Therapie der nutzbaren Hausthiere* (Vienna, 1869); Rohlwehs, *Allgemeines Vieharzneibuch* (21st ed., remodelled by H. Renner and M. Rothermel, Berlin, 1874); Finlay Dun, "Veterinary Medicines, their Actions and Uses" (Edinburgh, 1864); and George Fleming, "A Manual of Veterinary Science and Police" (2 vols., London, 1875).

VETIVER (Fr., from the East Indian *vitivayr*). Several grasses of the genus *andropogon*, which is largely represented in this country, have aromatic properties in a marked degree; in some cases these are important enough to make them or their products articles of commerce. The oil of lemon grass, so much used in modern perfumery (see LEMON GRASS), is from *A. schœnanthus*, and the roots of *A. muricatus*, as vetiver, are employed by the French perfumers. The last named species, which is very common in India, where it is known also as *kus-kus*, grows from 3 to 6 ft. high, with leaves 3 ft. long; no part of the plant has any marked odor, except the root; this consists of much-branching fibrous rootlets, which in the imported article are clumps of a few inches to a foot long; they have a strong odor, recalling that of myrrh, but more pleasant, which depends upon a resinous matter. In India the roots are used to preserve stuffs and clothing from insects, and are interwoven into screens of lattice work which are placed in the windows; when wetted they give to the air which passes through them a pleasing odor; palanquins are perfumed in the same manner, and the roots are used for making perfumed baskets and other small articles. As early as 1103 the root was received in India in payment for taxes.

VETO, a Latin word, signifying "I forbid," which has been introduced into the political language of modern nations to signify the act by which the executive power refuses its sanction to a measure proceeding from the legislature. The first instance of the use of this power was by the tribunes of the people in Rome, who, by pronouncing the word *veto*, could render of no avail the decrees of the senate or the proceedings of the magistrates. Under the ancient Polish constitution any single member of the diet, by the use of the *liberum veto*, saying *Nie pozwalam* (I do not allow), could hinder the passage of any measure. At the beginning of the French revolution the national assembly, in forming the constitution, allowed the king a conditional veto only; but the absolute veto was restored to the monarchy after the fall of Napoleon. The sovereign of England has theoretically a veto upon the measures of parliament, but it is a power which has not been used since 1707. In Norway the king has a veto; but if three successive storthings pass the same measure, it becomes a law in spite of the veto. In Sweden and the Netherlands the king has a full veto, and in other European countries there is an equivalent authority wherever the assent of the monarch is necessary to a law. The president of the United States has a veto power, which has very frequently been exercised; but a majority of two thirds in each house of congress is sufficient to pass any measure over the veto. A similar conditional power over the acts of their respective legislatures is given to the governors of the several states, with the exception of Delaware, North Carolina, Ohio, Rhode Island, and West Virginia. In several of the states the veto may be overruled by a majority vote, but in most of them a majority of two thirds is required. Mayors of cities generally have a like power.

VEUILLOT, Louis, a French author, born at Boynes, department of Loiret, in 1813. He is the son of a poor cooper, obtained a place in an attorney's office in Paris, and at the age of 19 his articles in the *Écho de la Seine-Inférieure* involved him in two duels. At the end of 1832 he became the editor-in-chief of the *Mémorial de la Dordogne*, at Périgueux. In 1837 he went to Paris as editor of the *Charte de* 1830, founded by the ministry; and when that journal failed, he became principal editor of the *Paix*. Hitherto he had been distinguished for boldness and skepticism; but having in 1838 visited Rome during Holy Week, he returned to France a zealous Catholic. In 1842 he went to Algeria as secretary of Gen. Bugeaud, and on his return became chief clerk in the ministry of the interior. In 1848 he became editor-in-chief of the *Univers*, on which he had been employed several years. While advocating extreme ultramontane views, he sided with the abbé Gaume in denouncing the use of the pagan classics in the Jesuit and other colleges, and with Padre Ventura in combating the Jesuit philosophy as too rationalistic. His journal was interdicted in many dioceses, and in 1853 the bishop of Orleans expressly forbade his clergy to read it. In 1860 it was suppressed by the emperor, but was allowed to reappear in 1867 with Veuillot as chief editor. During the discussions which preceded the council of the Vatican, the *Univers* was the foremost organ of the infallibilists. Veuillot resided at Rome during the council as the chief correspondent of his paper. He has written numerous works, relating principally to the tenets of the Roman Catholic church, and often bitterly attacking everything that came in conflict with what he conceived to be ultramontane doctrines and interests. His latest work is *La vie de Jésus-Christ.*

VEVAY, or **Vevey** (anc. *Vibiscum*), a town of Switzerland, in the canton of Vaud, 10 m. S. E. of Lausanne; pop. in 1870, 7,881, chiefly Protestants. It is beautifully situated at the mouth of the gorge of the Veveyse, on the N. E. margin of the lake of Geneva opposite a range of mountains, is built in a triangular form, and has a large market place lined with fine buildings. St. Martin's church contains the tombs of the regicide Ludlow and of Broughton, who read the death sentence to Charles I. The other principal church is St. Clara's, and there is an English chapel. The corn magazine is remarkable for its marble pillars. A marble bridge spans the Veveyse, and the lake shore is provided with quays. Vevay is the centre of an active transit trade. A vintage festival, traced by some authorities to the worship of Bacchus in the days of the Romans, and by others to mediæval monastic usages, is held at intervals of 15 or more years; the last was held in 1865. Vevay is associated with many celebrated personages, and especially with Jean Jacques Rousseau, whose favorite inn, in the Grande Place, has been converted into a coffee house. The scenery increases in magnificence within a few miles N. E. of Vevay, and attracts in summer multitudes of tourists, not a few of whom become permanent residents in consequence of the fine climate and the cheapness of living.

VIARDOT. I. Louis, a French author, born in Dijon, July 31, 1800. He studied law in Paris, and wrote for the newspapers. In 1838 he joined Robert in managing the Italian opera, became sole director in 1839, and brought out Mario and Pauline Garcia, whom he married in 1840. In 1841 he joined George Sand and Pierre Leroux in founding the *Revue indépendante*, and he afterward accompanied his wife in her artistic journeys. His works include *Essai sur l'histoire des Arabes et des Maures d'Espagne* (2 vols., 1832); *Études sur l'histoire des institutions et de la littérature en Espagne* (1835), translated into Spanish; *Souve-*

nirs de chasse (1849; 6th ed., 1854); *Histoire des Arabes et des Maures d'Espagne* (2 vols., 1851); *Les merveilles de la peinture* (1868 *et seq.*); and various works on Spanish and Italian art and on European art collections. He made many translations, comprising *Don Quixote* and novels by Cervantes, Toreno's history of the rising in Spain (5 vols., 1838), and select Russian works by Gogol, Pushkin, and Turgeneff (1853–'60). An English edition of his works on Italian art appeared in 1870, entitled "Wonders of Italian Art." **II. Michelle Pauline Garcia,** a French vocalist, wife of the preceding, born in Paris, July 18, 1821. She studied vocal music under her father, Manuel Garcia, and at a later period Liszt perfected her on the piano. In 1825 she was taken with the Garcia troupe to America, and after their return in 1828 she sang in the concerts of her sister Mme. Malibran. She first appeared in opera at London in May, 1839, as Desdemona in Rossini's *Otello*, and in *La Cenerentola.* She married M. Viardot in 1840, and with him made tours to the principal European capitals. In Paris she created in May, 1848, the character of Fidès in *Le prophète*, one of her masterpieces, in which she appeared at Berlin, St. Petersburg, and London. In 1860 she had a brilliant success at the Théâtre Lyrique, Paris, in Gluck's *Orfeo.* She possesses a mezzo-soprano voice of remarkable compass and elasticity, and is able to sing with almost equal facility in French, Italian, German, Spanish, and English; and her dramatic genius is remarkable. She has composed a short opera, *L'ogre*, for which Turgeneff wrote the text, performed in 1868 during her residence in Baden-Baden, and another in two acts, *Le dernier magicien*, performed in 1869 at the court of the grand duchess of Saxe-Weimar. Mme. Viardot has been for some years a professor of music at the conservatory of Paris.

VIATKA. I. An E. government of European Russia, bordering on Vologda, Perm, Ufa, Kazan, Nizhegorod, and Kostroma; area, 59,114 sq. m.; pop. in 1870, 2,406,024, including Tartar tribes and about 50,000 Mohammedans. The surface is mountainous in the east, where ramifications of the Ural range extend, and level or undulating in other parts. The principal rivers are the Kama, an affluent of the Volga, dividing it from Ufa, and its tributaries, the Viatka, Tcheptza, and Kilmez, all navigable. The climate is severe. Grain, flax, hemp, tallow, honey, and wax are exported to Archangel, and furs, iron, and copper are also produced. Woollen and linen goods and iron and copper ware are manufactured. **II.** A city, capital of the government, on the Viatka, 195 m. N. by E. of Kazan; pop. in 1867, 19,885. It has a fine cathedral and many other churches, a gymnasium, a seminary, important manufactories of woollen and other goods, and extensive silver and copper works.

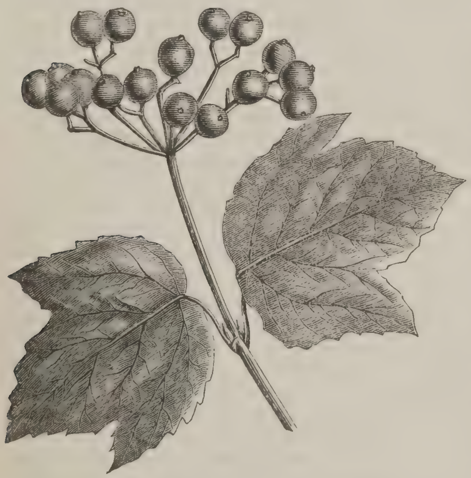
VIBERT, Jehan Georges. See supplement.

VIBORG. I. A S. E. län or government of Finland, Russia, bordering on the gulf of Finland; area, 16,611 sq. m.; pop. in 1872, 276,884, chiefly Karelians. Lake Ladoga partly belongs to its territory, and it contains Lake Saima, which establishes communication between the various watersheds and the gulf. The principal occupations of the inhabitants are agriculture and mining. **II.** A town, capital of the län, on a deep inlet of the gulf of Finland, 74 m. N. W. of St. Petersburg; pop. in 1867, 8,722. It has a gymnasium, a female high school, and a considerable export trade.

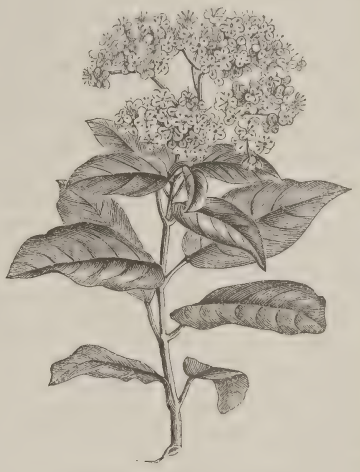
VIBRIO (Müll.), the type of the *vibrionia*, a family of minute colorless organisms, arranged by Ehrenberg and Dujardin among infusorial animals from the possession of apparently voluntary motions, but now generally considered as microscopic plants, compound or confervoid algæ of the tribe *oscillatoriaceæ.* They are exceedingly minute, requiring the highest powers of the microscope to make out any structure; they appear like slender lines, straight or sinuous, composed of minute joints, without any visible organs of motion, though possessing contractility; they seem to be propagated by the formation of new joints and subsequent separation at one of the articulations; their structure is best seen when dried. They appear suddenly in artificial infusions, and grow rapidly in such immense numbers as to form a thick scum on the surface; they are also found in the tartar on the teeth, in purulent discharges, and in other morbid fluids. The species of the genus *vibrio* have an undulatory and sinuous motion, like a serpent; in *spirulina*, which is coiled in a long spiral, the movements are gyratory and oscillating. In *vibrio* there is a single, straight row of filaments, without apparent sheath; *V. subtilis*, about $\frac{1}{430}$ of an inch long and $\frac{1}{24,000}$ wide, is aquatic and found in pools; some of the other species are probably the earlier stages of other unknown algæ.—The so-called "eels" of vinegar and sour paste, sometimes erroneously styled vibrios, are nematoid worms or entozoa; they were once popular microscopic objects. They belong to the genus *anguillula* (Müll.); the *A. aceti* or vinegar eel is $\frac{1}{30}$ to $\frac{1}{17}$ of an inch long, and the *A. glutinis* or paste worm $\frac{1}{15}$ of an inch; their absence in vinegar is due to the freedom from mucilage and the usual addition of a little sulphuric acid.

VIBURNUM, an ancient name of a genus of monopetalous shrubs or small trees of the honeysuckle family (*caprifoliaceæ*), in which there are about 80 species; the majority are natives of North and South America, a few being found in Europe and Asia. The viburnums have opposite and simple leaves, and small white flowers in terminal, flat, compound cymes; the very minute flowers consist of a calyx, the tube of which is coherent with the ovary and five-toothed, a deeply five-lobed spreading corolla, and five stamens; the one- to three-celled ovary is surmounted by a short three-lobed style, and ripens into a one-celled, one-seeded drupe, containing a single flattened stone.

There are about a dozen species in the United States, some of which, in the northern portions at least, form a considerable part of the coppice and undergrowth of woods. In two of our species the flowers upon the margin of the cyme are sterile and their corollas are greatly enlarged, forming a showy border to the cluster; a garden form of one of these, *V. opulus* (also a native of Europe), has all of the flowers sterile and showy. (See GUELDER ROSE.) The other species with sterile flowers is called hobble-bush, for the reason that its straggling reclining branches take root where they touch the ground, and impede the traveller; it is found in cold woods from New England to Pennsylvania, and further south along the mountains; its round-ovate leaves are heart-shaped at base, serrate, 4 to 8 in. across, with the veins and stalk covered with a rusty scurf; the heads of flowers are broad and showy, and the crimson fruit is not edible. This species is named *V. lantanoides* from its resemblance in leaves, though not in flowers, to *V. lantana* of Europe, which is there called the wayfaring tree on account of its frequent occurrence on the roadside; and our shrub is sometimes called the American wayfaring tree. Of the remaining species, without the conspicuous sterile flowers, the following deserve a special mention. The sweet viburnum, or sheep berry (*V. lentago*), is one of the most frequent northern species; it has ovate, strongly pointed, very sharply serrate leaves, with margined petioles; the flower clusters are terminal and axillary, appearing in great abundance in May and June, and have a pleasant fragrance; the oval fruit, shining blue-black, half an inch or more long, is showy, sweet, and edible. This is one of our most beautiful shrubs, and when unmutilated (for cattle are fond of browsing on it) is sometimes a tree 20 to 30 ft. high. It has been successfully used to form an ornamental hedge. Arrowwood is the common name for another abundant species (*V. dentatum*), which is widely distributed; it sometimes reaches 15 ft., but is usually only 5 or 8 ft. high; its leaves, from half an inch to an inch long, have very large and sharp teeth and strong veins; the fruit is bright blue. The maple-leaved viburnum (*V. acerifolium*), which in some parts of the country is called dockmackie, rarely grows above 6 ft., and may be readily mistaken when not in flower for a young maple sapling; its three-ribbed and three-lobed leaves are from 2 to 4 in. long and broad, and irregularly toothed on the margin; the fruit, at first crimson, turns to blackish purple and is inedible; it is very common in rocky woods. The most important exotic species is *V. tinus*, which is not rare as a house plant under the name of laurestinus; it is a native of southern Europe; it has evergreen leaves and clusters of flowers which are rose-colored in the bud, but white when open; it continues long in flower, and is much valued for the house and for decoration.



Maple-leaved Viburnum (V. acerifolium).



Laurestinus (Viburnum tinus).

VICENTE, Gil, a Portuguese dramatist, born about 1470, died in 1557 (according to some, about 1540). He belonged to the nobility, and studied law at Lisbon. His first work was a monologue written in 1502 on occasion of the birth of Prince John, afterward John III., which was recited before the royal family, and pleased the queen mother so much that she requested the author to repeat it at Christmas, adapting it to the birth of the Saviour. From this time he continued to produce dramatic works at the court, and he has been called the Plautus of Portugal and the father of the Portuguese drama. He wrote 42 pieces, consisting of *autos* or miracle plays, comedies, tragi-comedies, and farces, of which 10 were written wholly and 15 partly in Castilian. His works were edited by his son Luiz (Lisbon, 1561), and in an edition of 1585 much was suppressed by the inquisition. A complete new edition has been issued by Barreto Feio and Monteiro (3 vols., Hamburg, 1834).

VICENZA. **I.** A N. E. province of Italy, in Venetia, bordering on Tyrol and the provinces of Belluno, Treviso, Padua, and Verona; area, 1,016 sq. m.; pop. in 1872, 363,161. The principal towns are Vicenza and Bassano. In the north the surface is traversed by several offsets from the Alps, but in the south it is level or undulating. The most important rivers are the Bacchiglione and the Brenta. There are considerable tracts of forest with much valuable timber; abundant chestnut trees furnish food for a great part of the population. The level country is remarkably fertile. A large quantity of silk is produced. Cattle and sheep are numerous. Several coal mines are worked, and silk, linen, and woollen goods, hardware, porcelain, paper, gold and silver articles, and leather are manufactured. It is divided into 10 districts. **II.** A city (anc. *Vicentia* or *Vicetia*), capital of the province, in a fine hilly region, at the junction of the Bacchiglione and Retrone, 37 m. W. by N. of Venice; pop. in 1872, 37,686. To Palladio, who was born here, is ascribed the finest of the eight bridges, and he built many of the celebrated public and private palaces. Among the former are the town hall and the prefecture. The finest square is the piazza dei Signori, in which are the two columns characteristic of most Venetian cities. In the market place is a remarkable belfry 270 ft. high and only 23 ft. wide. Of the 19 churches, the cathedral and the church of S. Lorenzo, and especially Sta. Corona near the Corso, are noteworthy for their architecture and pictures. Palladio began to build in the piazza d'Isola the teatro Olimpico, on the ancient plan, and it was completed by his son; it is now in a rather dilapidated condition. In the museum is a large picture gallery, and there are several gymnasia, a lyceum, a college, and a palace for the resident bishop. The sanctuary of Monte Berico is joined to Vicenza by arcades beginning at the triumphal arch of the Lupia gate; at the foot of it is Palladio's villa, copied in the duke of Devonshire's villa at Chiswick, and described by Goethe as a marvel of splendor. The finest promenade is the Campo Marzio, which contains a triumphal arch and the railway station. The *campo santo* or cemetery is an extensive building with many fine monuments.—Vicentia was a *municipium* of Venetia under the Romans. In the 12th century the city was among the earliest members of the Lombard league against the emperor Frederick I. In 1236 it was devastated by Frederick II. Henry VII. gave Vicenza in fief to the Scala family, and this and other local families were at the head of the government until it passed in 1404 to the Venetians, who recovered it in 1516 after it had been for some time in the hands of Maximilian I. It came into the possession of Austria in 1815. In 1848 Vicenza rose against the Austrians, who bombarded it in May and June, and it surrendered on June 11 to Radetzky.

VICENZA, Duke of. See CAULAINCOURT.

VICHY, a town of France, in the department of Allier, on the right bank of the river Allier, which is here crossed by a suspension bridge, 30 m. S. of Moulins; pop. in 1872, 6,028. It consists of an old and a new town, known as Vichy-la-Ville and Vichy-les-Bains. There are several churches and hospitals, a fine park, a new English park, and a casino consisting of three parts joined by two arcades. It has eight principal springs. (See MINERAL SPRINGS.) The season lasts from May to October. Under the second empire, when the place was greatly improved and enlarged, the annual visitors numbered over 15,000.

VICKSBURG, a city and port of entry of Mississippi, county seat of Warren co., on the E. bank of the Mississippi river, about 400 m. above New Orleans and nearly the same below Memphis, Tenn., and on the Vicksburg and Meridian railroad, 45 m. by rail W. of Jackson, the state capital; pop. in 1850, 2,678; in 1860, 4,591; in 1870, 12,443, of whom 6,805 were colored and 1,416 foreigners; in 1875, locally estimated at 15,000. The site is elevated and very uneven, rising in terraces from the river. The streets are narrow but regularly laid out, and some of them are paved. The court house is a magnificent building, which cost about $150,000. About 3 m. N. of the city is an extensive national cemetery. Steamers run tri-weekly to St. Louis, and almost daily to New Orleans. The North Louisiana and Texas railroad, starting from the opposite bank of the Mississippi, extends to Monroe, La. The Vicksburg and Ship Island railroad is in course of construction. Vicksburg is surrounded by a rich cotton-growing region, and is the principal commercial point between Memphis and New Orleans. About 200,000 bales of cotton are shipped annually. The chief manufactories are one of cotton-seed oil, consuming 500 bushels of seed a day, a rolling mill and foundery, the railroad car works, two machine shops, two breweries, four planing mills, several saw mills, a manufactory of boilers, and several of carriages and wagons and of saddlery and harness. There are two banks, with a joint capital of $250,000; four public schools, with an average attendance of about 1,000, white and colored, besides two Roman Catholic and two private schools; a daily and three weekly newspapers; a city hospital; and eight churches, Baptist, Episcopal (2), Jewish, Methodist (2), Presbyterian, and Roman Catholic, besides three or four for colored people. Vicksburg was settled in 1836 and incorporated in 1840.—As early as January, 1861, immediately after the adoption by Mississippi of the ordinance of secession, the governor of the state planted guns at Vicksburg to detain for examination all steamers passing down the river. The capture of New Orleans in April, 1862, gave the federals virtual possession of the Mississippi to this point, down to which the operations from above had cleared the river. On May 18 a portion of Farragut's fleet, under Capt. S. P. Lee, passing up the river, appeared before Vicksburg, and demanded its surrender on pain of bombardment; this was peremptorily refused, but no bombardment ensued. The fortifications on the river side were strengthened, and in June were held by a confederate force estimated at 10,000. On the 28th Gen. Williams with four regiments and eight field guns came up the river and took position opposite the city on the Arkansas side, and began digging a canal across the narrow isthmus formed by the sharp curve of the river. The design was to form a new channel, and thus leave Vicksburg several miles inland; but the river, which often forms for itself a new channel in a single night, refused to pass through that provided for it, and kept on its old course around the bend. On June 28 Farragut bombarded Vicksburg, and succeeded in passing the batteries with little damage; but he thought the place could not then be taken without the coöperation of an army of 12,000 or 15,000 men. Late in August the river began to fall; Farragut was obliged to descend to New Orleans, and for five months no further operations were undertaken against Vicksburg. Meanwhile the confederates had commenced fortifications at Port Hudson on a high bluff about 120 m. below Vicksburg, nearly midway between that city and New Orleans; these soon became very strong, and it seemed necessary to capture them also in order to hold the whole course of the Mississippi. Gen. Pemberton, a personal favorite of President Davis, was made a lieutenant general, although he had seen little service, and was placed in command at Vicksburg, subject to the orders of Gen. J. E. Johnston, who at that time commanded all the forces in Tennessee and Mississippi. Gen. Grant, who commanded the Union forces in these departments, had late in the autumn penetrated far into Mississippi, and in December had approached Vicksburg with about 40,000 men, Pemberton having about 34,000. Grant then sent Gen. W. T. Sherman to attack Vicksburg. His force, when increased from other quarters, was about 42,000. On the 25th Sherman's troops went in transports up the Yazoo river, which falls into the Mississippi a few miles above Vicksburg, whence he endeavored to make his way through a swampy region intersected by numerous bayous. After several skirmishes, it was found impossible to force a passage through the swamps, which were passable only by narrow causeways, commanded by batteries, and the attempt was abandoned on Jan. 1, 1863. The entire Union loss was 191 killed, 982 wounded, and 756 missing; that of the confederates was about 150 in all. On the 4th Sherman was superseded in this command by Gen. McClernand, though retaining that of his own corps, the 15th. Grant soon after took command of all the forces operating against Vicksburg. During several weeks he made repeated attempts to find some means by which his army could go by water to some point below the place, and attack it in the rear from the south. The first canal across the isthmus having proved a failure, he undertook to cut a second one further inland; but that was likewise useless, and Grant determined to march the bulk of his army by land, on the western side of the Mississippi, to a point below, cross the river, strike eastward to Jackson, the state capital, and then turning west move upon Vicksburg, taking it in the rear. Finally, on April 30, after an unsuccessful attack on the 29th upon Grand Gulf by Porter's gunboats, which had passed the batteries at Vicksburg, the army reached a point opposite Bruinsburg, where a crossing was effected, and the march toward Jackson began. On May 1 a brisk engagement took place at Port Gibson, 12 m. N. E. of Bruinsburg; the confederates were driven off with a loss of about 700. Grant had left Sherman behind at Milliken's bend, above Vicksburg, to make a feint from that quarter, after which he was to follow on and rejoin the main army. This having been done, the whole resumed their march toward Jackson. Johnston, who had received some reënforcements, sent a few brigades to oppose the advance; these were defeated at Raymond on the 12th, and driven back to Jackson, where Grant arrived on the 14th and burned the workshops, arsenal, and railway depot. Pemberton in the mean while had moved out with 18,000 or 20,000 men as far as Baker's creek or Champion hills, about half way between Vicksburg and Jackson, where Grant attacked him on the 16th, driving him back in confusion to the Big Black river, here crossed by a railroad bridge. There the attack was renewed with success on the morning of the 17th, and on the 18th the Union army crossed the Big Black on floating bridges, and began the formal investment of Vicksburg, just a year from the time when its surrender had been first demanded by Farragut's gunboats. Pemberton contracted his lines, abandoning Haines's bluff, and concentrating all his force in the works around Vicksburg. He had about 25,000 effective men, but was deficient in small ammunition, especially in gun caps, and had rations for only 60 days, with no prospect of more unless the investment could be broken. Johnston, whom illness had prevented from taking personal command there, wrote to Pemberton: "If Haines's bluff is untenable, Vicksburg is of no value and cannot be held; if, therefore, you are invested there, you must ultimately surrender. If it is not too late, evacuate Vicksburg and its dependencies, and march to the northeast;" and he himself moved in such a direction as to expedite a junction. Pemberton replied that it was impossible to withdraw the army, adding: "I have decided to hold Vicksburg as long as possible, with the firm hope that the government may yet be able to assist me in keeping this obstruction to the enemy's free navigation of the Mississippi river. I still conceive it to be the most important point in the confederacy." Hoping to carry the place by a *coup de main*, Grant attacked Pemberton's lines on May 19, but was repulsed, and began a regular siege. He was soon reënforced so as to have nearly 70,000 men, with whom he maintained the investment till the morning of July 3, when Pemberton sent him a note asserting that he was fully able to maintain his position for an indefinite period, but proposing that commissioners should be named on both sides to arrange terms of capitulation. Grant consented to meet Pemberton in person to arrange the terms. The meeting took place at 3 o'clock in the afternoon, and the actual surrender followed next morning. The paroled prisoners numbered about 27,000, of whom about three fifths were fit for duty in the trenches, the remainder being sick or wounded. The Union loss, from the crossing at Bruinsburg, April 30, to the surrender, was 943 killed, 7,095 wounded, and 537 missing; in all, 8,575, of whom 4,236 were before Vicksburg. The confederate loss is estimated at about 10,000.

VICO, Francesco de, an Italian astronomer, born in Macerata, May 19, 1805, died in London, Nov. 15, 1848. He was educated at the college of Urbino, and became in 1835 assistant superintendent, and in 1839 director of the observatory of the Roman college. In 1848, when the Jesuits were driven from Rome, he came to the United States. He died while in Europe for the purpose of purchasing instruments for an observatory to be erected under his direction in the state of New York. His fame as an astronomer rests on his observations of the ring system of Saturn and spots of Venus, and his discovery of seven or eight comets. He was also an excellent composer of church music.

VICO, Giovanni Battista, an Italian author, born in Naples about 1668, died Jan. 20, 1744. He was educated by the Jesuits and studied law, but never practised. For nine years he was tutor in jurisprudence to a nephew of the bishop of Ischia, and afterward for about 40 years professor of rhetoric at Naples. In 1735 he was appointed historiographer to the king. He wrote *De Ratione Studiorum* (1708), *De Antiquissima Italorum Sapientia* (1710), and *De uno Universi Juris Principio et Fine* (1720), all in a manner introductory to his main work, *Principii di una scienza nuova d'intorno alla commune natura delle nazioni* (1725), which is at once a history of civilization, a natural history of mankind, and a philosophy of law. Vico may be regarded as the founder of the philosophy of history. He places Divine Providence at the basis of all history, and shows its working in language, mythology, religion, law, and government. One of the best editions of his works is by Ferrari (7 vols., Madrid, 1834–'7).

VICQ D'AZYR, Félix, a French physician, born at Valogne, Normandy, April 28, 1748, died in Paris, June 20, 1794. In 1765 he went to Paris to complete his studies, and in 1773 he opened public courses of lectures on human and comparative physiology; but the jealousy of other professors finally obliged him to give private lectures. Daubenton, whose niece he had professionally attended and then married, enabled him to extend his sphere of activity. He was admitted to the academy of sciences in 1774, and Lassonne, the king's physician, employed him in official investigations of the murrain then raging in southern France, which ultimately led to the establishment of the royal medical society, of which he became perpetual secretary. In this capacity he delivered eulogies on Linnæus, Franklin, and others. In 1788 he succeeded Buffon in the French academy, the annals of which he enriched with numerous contributions. In 1789 he became first physician to Marie Antoinette. His devotion to her gave umbrage to the revolutionists, and they obliged him to attend Robespierre's festival of the Supreme Being (June 8, 1794), an ordeal which gave the final blow to his shattered health. His works include *La médecine des bêtes à corne* (2 vols., 1781); *Traité d'anatomie et de physiologie*, and *Système anatomique des quadrupèdes* (2 vols., 1786–'92); and *Système anatomique* (4 vols., 1791–1822). Moreau (de la Sarthe) delivered a eulogy on him in 1797, and Lemontey in 1827; Moreau edited a collection of his works (6 vols., 1805).

VICTOR (VICTOR-PERRIN), **Claude,** duke of Belluno, a French soldier, born at Lamarche, Lorraine, Dec. 7, 1764, died in Paris, March 1, 1841. He entered the army as a private in 1781, became a major in 1791, and was made brigadier general for his efficiency in the siege of Toulon, where he was twice wounded, but was not confirmed in that grade till 1795. In 1797 he was made general of division after brilliant services in Italy, where in 1800 he contributed largely to the victories of Montebello and Marengo. He was commander-in-chief of the Gallo-Batavian army in 1800–'2, was next appointed captain general of Louisiana, and in 1803 resumed the former office. In 1805 he went as minister to Copenhagen. In the following year he operated against the Prussians, into whose hands he fell while travelling in 1807, but was exchanged for Blücher. In the same year he was made marshal and duke after the battle of Friedland. In 1808 he was sent to Spain in command of the first corps, gained several victories and contributed chiefly to the capture of Madrid, shared in the defeat of Talavera, and in 1810 commenced the prolonged siege of Cadiz. In 1812 he served on the reserve in Russia, covering the retreat of the army across the Beresina. In 1813 he coöperated in the capture of Dresden and in the battles of Leipsic and Hanau. In March, 1814, he was severely wounded at Craonne. After the first restoration he adhered to the Bourbons, remained faithful during the hundred days, and was made a peer. Placed at the head of an investigating committee, he showed great severity toward those of his former comrades who had gone over to Napoleon. He was minister of war from 1821 to 1823, when he accompanied the duke of Angoulême as major general to Spain, but was recalled on account of frauds for which he was partly held responsible. He was appointed ambassador to Austria, but that government declined to recognize him as duke of Belluno, and he spent the rest of his life in retirement.

VICTOR AMADEUS II., duke of Savoy and afterward king of Sardinia, born May 14, 1666, died Oct. 31, 1732. In 1675 he succeeded his father Charles Emanuel II., under the regency of his mother, against whose wishes he married in 1684 a niece of Louis XIV., who regarded Savoy as a vassal state. At that monarch's request he persecuted the Waldenses, and sent auxiliary troops to the French army in Flanders; but as Louis insisted upon his control of the whole army of Victor Amadeus, he joined in 1690 the Augsburg league against France. This contest, in which he displayed great valor, was nearly fatal to him; but he obtained in a treaty with Louis XIV. (1696) the restoration of important territories occupied by the French, and a large indemnity in money, and joined the French army with his troops. His defection contributed to the termination of the war of the Augsburg league, through the treaty of Ryswick of 1697. After the outbreak of the war of the Spanish succession, as Louis XIV. refused to purchase his alliance by a cession of territory, he again turned against him, and, defeating the French, who had overrun Savoy and Piedmont, with the aid of Prince Eugene, he recovered all his possessions, and in 1713, by the treaty of Utrecht, received additionally a part of the duchy of Milan and the kingdom of Sicily, and on Dec. 24 was crowned at Palermo. In 1720 he exchanged Sicily for the island of Sardinia, which was then held by Austria, and assumed the title of king of Sardinia. On Sept. 3, 1730, he abdicated in favor of his son Charles Emanuel III. A short time before he had secretly married his mistress, the countess of San Sebastiano, whom he made marchioness of Spigno. At her instigation he made in 1731 repeated but futile attempts to regain his throne. He was imprisoned in September by order of his son, who was goaded on to this step by his courtiers and chiefly by the archbishop of Turin. He was dragged from his bed and confined for several days at the Rivoli palace, and then conveyed to Moncalieri, where he ended his life in captivity. His wife, who was permitted to join him, retired on his death to a convent in Turin, where she died in 1733.

VICTOR EMANUEL I., king of Sardinia, born in 1759, died at Moncalieri, near Turin, Jan. 10, 1824. He was the second son of Victor Amadeus III., and succeeded his brother Charles Emanuel IV., who abdicated in his favor in June, 1802. The French were then masters of the continental parts of his kingdom, and Victor Emanuel, after a residence of four years in Naples, in the vain hope of recovering his possessions, resided in the island of Sardinia under the protection of Great Britain till 1814, when he was reinstated on the throne. By the treaties of Vienna he ceded several districts to Geneva, and obtained the territory of Genoa. His extreme reactionary policy resulted in his overthrow by an insurrection in 1821, when he was obliged to abdicate, March 13, in favor of his brother Charles Felix.

VICTOR EMANUEL II. (VITTORIO EMMANUELE MARIA ALBERTO EUGENIO FERDINANDO TOMMASO), king of Italy, formerly king of Sardinia, born in Turin, March 14, 1820, died in Rome, Jan. 9, 1878. He was the eldest son of Charles Albert and Theresa, daughter of the grand duke Ferdinand of Tuscany. He received a careful education, and in 1842 married the archduchess Adelaide of Austria. When the war with Austria broke out in 1848, he took command of the brigade of Savoy, and followed his father to the field, participating in the battle of Goito, where he received a ball in the thigh. In his father's second war he won the admiration of the army by his valor at the disastrous battle of Novara, March 23, 1849. Immediately after this defeat Charles Albert abdicated in favor of his son, who thus came to the throne with a peace to make with a victorious enemy and a fierce conflict of faction to appease at home, while his alliance with an Austrian princess was regarded with distrust. The selection of his first cabinet under D'Azeglio tended to reassure the liberals. He soon effected a reorganization of the finances and of the army, signed a peace with Austria, and under the influence of Cavour, who till his death remained the principal adviser of the king, curtailed the privileges of the clergy, secularized the property of the church, and took from the religious associations the monopoly of education. Excommunicated by the pope on account of these measures, he issued a protest in the form of a *memorandum*. Within a brief period in 1855 he lost his mother, his wife, his brother, and his youngest child, and himself fell dangerously ill. By a treaty signed April 10, 1855, he joined the Anglo-French alliance in the Crimean war, and the position of Sardinia among the European states was greatly raised, mainly through the influence of Cavour. The marriage of his daughter Clotilda to Prince Napoleon (January, 1859) was followed almost immediately by the war of Italian independence, in which France and Sardinia took the field together against Austria. Victor Emanuel, invested with dictatorial powers, led his troops in person, accompanied by the heir apparent, Prince Humbert, to whom, though he was only 15 years old, he gave the command of a brigade. The king won the name of *rè gallantuomo* by his intrepidity at the battle of Palestro and by his valor on all occasions. After the battle of Magenta he entered Milan with Napoleon III., and on the field of Solferino found himself face to face with the Austrian general Benedek, whom he defeated after a severe fight. An interview at Villafranca between the French and Austrian emperors (July 11) settled the preliminaries of the treaty of peace, which was signed at Zürich (Nov. 10), and gave Lombardy to Victor Emanuel, excepting the fortresses of Mantua and Peschiera. In March, 1860, Savoy and Nice were ceded to France. In the course of the same year Victor Emanuel annexed Parma, Modena, and Tuscany, the rulers of which had been expelled by insurrections in 1859, a large part of the Papal States, and the Two Sicilies, the latter chiefly through the aid of Garibaldi; and on March 17, 1861, he assumed the title of king of Italy, bestowed on him by the Italian parliament on Feb. 26. In 1866, after a short war against Austria in alliance with Prussia, Venetia was incorporated in his dominions, and in 1870 the residue of the Papal States; and his capital, removed in 1865 from Turin to Florence, was transferred to Rome in 1871, where the king made his official entrance, July 2, taking up his residence at the Quirinal. For a fuller account of the events of his reign, the 25th anniversary of which was celebrated with great solemnity in March, 1874, see ITALY. The king's second daughter, Pia, is the present queen of Portugal; and his second son, Amadeus, was king of Spain from December, 1870, to February, 1873. (See AMADEUS I.) Victor Emanuel's morganatic wife was Rosa Vercellana, whom he made countess de Mirafiore.

VICTORIA, a British colony in S. E. Australia, between lat. 34° and 39° 9′ S., and lon. 141° and 150° E., bounded N. E. and N. by New South Wales, from which it is separated by the Murray river, W. by South Australia, and S. by the Pacific ocean and Bass strait, which separates it from Tasmania; area, 86,831 sq. m.; pop. in 1871, 729,868; estimated, Dec. 31, 1874, 808,407. The coast line is more than 600 m. long. The W. part as far as Cape Otway is generally low; its principal harbors are Portland bay, Port Fairy, and Warnambool or Lady bay. Between Cape Otway and Wilson's promontory the coast rises in some places 500 and 1,000 ft. above the sea. Here the chief harbors are Port Phillip bay, which is nearly 40 m. long and of about the same width, and Western Port. Wilson's promontory is a granite headland rising 3,000 ft. above the sea, connected with the mainland by a sandy isthmus. A peninsula extending N. from it forms Corner inlet, a bay well protected by sandy islands. Thence to Cape Howe, the most easterly point of Victoria, the coast is sandy, with many lagoons, the principal of which are Lakes Reeve, Wellington, Victoria, and King. The colony is divided into two unequal parts by a chain of mountains called the Dividing range, which runs E. and W., 60 or 70 m. from the coast. Its E. part, called the Australian Alps, varies from 1,000 to 7,000 ft. in height; its principal peaks are Mt. Hotham, Mt. Smyth, Mt. Selwyn, the Twins, Forest Hill, and the Cobboras. The part dividing the Wimmera district from Ripon county is called the Pyrenees; its principal peaks are the Coorong-ageering, the Jambour, and Ben Nevis. The W. end of the Dividing range forms the Grampians, the principal peak of which is Mt. William. There are many smaller ranges, several of which are spurs of the main range. Most of the rivers dry up in summer, but in winter are swollen into angry torrents. None but the Murray and the Yarra-Yarra are navigable. Besides these the principal rivers are the Goulburn, 230 m. long; Glenelg, 205 m.; Loddon, 150 m.; Wimmera, 135 m.; Avoca, 130 m.; Hopkins, 110 m.; Wannon, 105 m.; and Ovens, 100 m. There are many lakes, both salt and fresh, all of which are shallow, and some of them dry in summer. The largest is Lake Corangamite, 76 sq. m. Others are Tyrrell, Hindmarsh, Albacutya, Buloke, Connewarra, and Colac. Of the lagoons on the coast, Victoria covers 91 and Wellington 75 sq. m.—Geologically, Victoria is a mass of palæozoic rock, with large areas of granite and trap protruding through it. Its wealth in minerals is almost unparalleled, among its productions being gold, silver, copper, tin, zinc, iron, lead, antimony, cobalt, bismuth, manganese, molybdenum, coal, sulphur, kaolin, and bitumen; and of precious stones, the ruby, sapphire, topaz, garnet, and agate. It is estimated that one third of the area of the colony is occupied by gold-bearing rocks, only about one thirtieth of which has been properly explored.—The climate is mild, the mean temperature of summer being 66°, of winter 48°, and of the whole year 58°. In January and the early part of February, the hottest part of the summer, the thermometer frequently stands at 100° to 108°, and hot winds blow from the north; but they continue only 20 to 30 hours, and are succeeded by cool breezes from the south and southwest. In July, the coldest month, the thermometer rarely falls below the freezing point. The average rainfall is about 30 inches.—About three fourths of the soil of Victoria is available for agricultural and pastoral purposes. Along the coast the lands are light but fertile. Gipps Land, the S. E. part of the colony, is mostly rugged and mountainous, and remarkable for its minerals, but it contains large tracts suitable for grazing. The Murray district, in the east, is also mountainous and noted for mineral wealth, but it has vast plains of fine grass land, used as sheep runs, and some good agricultural land. The Wimmera district, occupying the whole of the northwest, consists chiefly of sandy, thinly grassed plains, with belts of myall scrub and forests of she-oak, box, and honeysuckle. The Loddon district is principally pastoral land, but contains some gold reefs in the S. part. The most useful of the native trees are the red and blue gums (eucalypti). The species called the peppermint attains a colossal height in the mountain ravines; a fallen tree near Healesville was 480 ft. long. Among the most numerous of the other indigenous trees are the *Banksia* or honeysuckle, she-oak, native cherry tree, and tea tree. Nearly everything grown in temperate climates thrives. Wheat, barley, and oats are the chief agricultural productions, but all the other grains and the legumes, roots, and grasses are largely raised. In 1875 there were 11,281,120 acres of enclosed land, of which 1,011,799 acres were under tillage; the total yield of wheat was 4,850,135 bushels, and of oats 2,121,612; wine produced, 599,093 gallons; and there were 180,254 horses, 11,221,036 sheep, 958,658 cattle, and 137,941 swine. For the indigenous animals, see AUSTRALIA.—Manufacturing industry has received a great impetus of late in consequence of being fostered by the government. In 1875 there were 1,545 manufactories, large and small, in the colony, the chief articles made being glass, paper, cloth, oil cloth, dyes, beer, starch, soap, cigars, pianos, safes, agricultural implements, engines, carriages, and brushes. There are 126 breweries, which in 1874 produced 13,653,531 gallons. The number of flouring mills was 161, most of which are worked by steam. Locomotives are now built at Ballarat; the first made in the colonies was delivered to the government on Feb. 6, 1873. But the most important industry of Victoria is gold mining, which in 1873 employed 52,544 men, of whom 13,528 were Chinese. The number of steam engines used in alluvial mining in 1874 was 353, of 9,317 horse power, and in quartz mining 788, of 15,549 horse power. The estimated value of all the machinery used in mining was £2,078,936; the number of quartz reefs worked or prospected was 3,398; and the number of companies registered was 143, with a nominal capital of £1,592,213. Many of the mining shafts are 500 to 1,000 ft. deep; in the Ararat district there is one nearly 1,500 ft. deep, and one has lately been sunk over 1,700 ft. The total amount of gold obtained from all the mines, from the discovery in 1851 to Jan. 1, 1875, was 44,414,177 oz., valued at £177,821,125. During 1874 the yield was 1,097,664 oz.; and during the first quarter of 1875, 257,641 oz. In the same year 18 mineral leases were issued for mining other metals than gold. The following shows the amount of other minerals produced in 1874: silver, 11,906 oz.; tin, 86,016 lbs.; iron ore, 130 tons; antimony ore, 111 tons; coal, 2,909 tons; and lignite, 750 tons.—The total value of the imports of Victoria in 1874 was £16,953,985; of the exports, £15,441,109. During the year ending March 31, 1875, there were exported 45,365,693 lbs. of greasy wool, 6,879,963 lbs. of scoured wool, and 36,416,355 lbs. of washed wool, all valued at £6,373,641. The number of vessels which entered the ports in 1873 was 2,187, of 756,103 aggregate tonnage, and 36,307 men.—The aboriginal population, which numbered about 5,000 when the colony was settled, had been reduced in 1871 to 1,330, of whom 784 were males and 546 females. The white population in 1871, of whom 401,050 were males and 330,478 females, were divided according to nationality as follows: natives of Australia and New Zealand, 356,936; England and Wales, 170,907; Scotland, 56,210; Ireland, 100,468; Germany, 9,264; United States, 2,423; France, 1,170; China, 17,857; other countries, 8,585; unknown, 3,514. There were 257,835 Anglicans, 170,952 Roman Catholics, 31,144 Presbyterians, 94,220 Wesleyans, 18,191 Congregationalists, and 47,513 of other Protestant sects. The number of churches and chapels in 1871 was 1,399, of which 229 were Anglican, 266 Presbyterian, 356 Wesleyan, 189 Roman Catholic, 91 Primitive Methodist, 61 Congregational, and 47 Baptist. Education is free, secular, and compulsory. In 1873 there were 1,936 schools and colleges, with 160,743 pupils and 4,257 teachers. Of these, 1,048 were common schools and 881 private schools. There were eight colleges and grammar schools, five of which are at Melbourne, two at Geelong, and one at Ballarat, and one university, at Melbourne, which had 134 students in 1872. Most of the large towns have public libraries; in 1875 there were 120 in all, with an aggregate of 162,540 volumes. In 1873 the public library in Melbourne had 75,500 volumes. Newspapers are published in all the large towns.—Victoria is divided into 38 counties. Besides the capital, Melbourne, the principal towns are Ballarat, Sandhurst, Geelong, Fitzroy (pop. 16,500), Castlemaine (7,500), Williamstown (7,200), Stawell (6,000), Daylesford (5,000), Warnambool (5,000), Hamilton (4,000), and Maryborough (3,500).—The government of Victoria consists of a governor appointed by the crown, whose term of office is seven years, an executive council, and a parliament of two houses, the legislative council and legislative assembly. The executive council consists of an attorney general, who is also premier, a treasurer, commissioners of trade and customs, of crown lands, of railways and roads, and of public works, a minister of mines and public instruction, a postmaster general, and a solicitor general. The legislative council consists of 30 members, representing six provinces into which the colony is divided, viz.: the central, northwestern, northeastern, southern, eastern, and western. The term of office is ten years, one member from each province retiring at the end of every two years. The qualification for members of this house is £2,500 freehold, or property of the value of £250 a year; for electors, a leasehold of £50 a year, or freehold property of the same value. In 1871 the number of electors in this class was 23,736. The legislative assembly contains 78 members, representing 49 electoral districts, who are elected for three years. Members receive £300 per annum. The qualifications for electors of this house are so small that universal suffrage may be said to prevail. In 1871 there were 142,305 voters in this class. All voting is by ballot. The net revenue of the government for the year ending June 30, 1875, was £4,132,118; the total expenditure, £4,325,277. The estimated revenue for 1875–'6 was £4,287,313; estimated expenditure, £4,488,658. The public debt on June 30, 1874, was £12,485,432, of which £10,657,000 had been expended on railway construction. The first railway in Victoria, from Melbourne to Sandridge, was opened in 1856. At the end of 1875 605 m. were in operation. The principal lines are: from Melbourne to Echuca, 156 m., with a branch from Castlemaine to Maryborough of 34 m.; Melbourne to Geelong, 45 m.; Geelong to Ballarat, 55¼ m.; Ballarat to Ararat, 57 m.; Ballarat to Dunolly, 56 m.; and Melbourne to Wodonga, 187 m. Lines are projected from Melbourne to Sale, 120 m.; Ararat to Hamilton, 64 m.; Sandhurst to Inglewood, 30 m.; Maryborough to Avoca, 15 m.; Leigh Road to Colac, 42 m.; and Portland to Hamilton, 55 m. In 1875 there were 3,928 m. of telegraph lines in operation, with 131 stations. There were 800 post offices and 210 money-order offices in the colony in 1873; income, £193,384; expenditure, £290,162. In 1875 the volunteer military force of the colony numbered 3,953 men, with 230 commissioned officers. The naval force comprised the cupola ship Cerberus of 2,100 tons and 4 guns, and the Nelson of 2,736 tons and 72 guns.—For the early history of Victoria, see Australia. The first settlement was made in 1835 on the W. shore of Port Phillip harbor, then included within the bounds of New South Wales. In 1839 was appointed the first superintendent of the district of Port Phillip, which had a population at that time of 3,511. An attempt was made in 1840–'41 to secure a separation from New South Wales, but independence was not achieved till 1851.

VICTORIA, a S. county of Texas, bounded E. in part by Garcitas creek, and S. W. by Coleto creek and Guadalupe river, the latter also intersecting it; area, 925 sq. m.; pop. in 1870, 4,860, of whom 1,768 were colored. The surface is low and level, and the soil fertile. The chief productions in 1870 were 71,078 bushels of Indian corn, 8,129 of sweet potatoes, 10,822 lbs. of butter, 14,871 of wool, and 205 bales of cotton. There were 5,047 horses, 2,044 milch cows, 62,303 other cattle, 5,445 sheep, and 4,069 swine. Capital, Victoria.

VICTORIA. I. A central county of Ontario, Canada, lying E. of Lake Simcoe; area, 1,305½ sq. m.; pop. in 1871, 30,200, of whom 14,157 were of Irish, 8,049 of English, 6,479 of Scotch, and 660 of French origin or descent. It is drained by Sturgeon lake and several streams, and is traversed by the Toronto and Nipissing and the Midland railways. Capital, Lindsay. **II.** A N. W. county of New Brunswick, Canada, bordering on Maine, and intersected by the St. John and Tobique rivers; area, about 1,900 sq. m.; pop. in 1871, 11,641, of whom 7,184 were of French, 1,696 of Irish, 1,509 of English, and 955 of Scotch origin or descent. Since the census Madawaska co. has been formed from the N. portion. The surface is rolling and varied, and remarkably fertile. Capital, Grand Falls. **III.** A county of Nova Scotia, Canada, comprising the E. portion of the N. projection of Cape Breton island; area, 1,198 sq. m.; pop. in 1871, 11,346, of whom 9,751 were of Scotch, 744 of English, and 665 of Irish origin or descent. The N. portion is mountainous and but scantily settled; the S. is better adapted to agriculture. Coal, iron, and salt abound, and gold and silver have been found. Capital, Baddeck.

VICTORIA, a city, port of entry, and the capital of British Columbia, on the strait of Fuca, at the S. E. extremity of Vancouver island, 65 m. S. S. W. of New Westminster, and 95 m. N. N. W. of Olympia, Washington territory; lat. 48° 27′ N., lon. 123° 25′ W.; pop. in 1870, 3,270. It has picturesque surroundings and a fine climate, except in winter, which is wet and stormy. On the N. border is a public park with a race course, surrounding an eminence called Beacon hill. Nearly all the stores and several of the churches are of brick and stone. The government buildings, of brick, occupy extensive grounds in the E. part of the city. Cary castle, the governor's residence, a large stone edifice costing $50,000, is in the suburbs. The city is lighted with gas and has water works. The inlet which forms the harbor runs N. for some miles with an average breadth of a few hundred yards. The entrance is narrow and tortuous, and does not admit vessels drawing more than 18 ft. Esquimalt, 3 m. distant, is used as a port by the largest vessels, and here are a British naval station and a naval hospital. There are fortnightly lines of steamers to New Westminster, Olympia, and San Francisco. The city contains four breweries, two distilleries, an iron foundery, a soap factory, two sash factories, two tanneries, a ship yard, two lumber yards, &c. There are two banks, a hospital, a theatre, two daily and two weekly newspapers, and Episcopal, Jewish, Presbyterian, Roman Catholic, and Wesleyan Methodist churches.—The Hudson Bay company established a fort and depot here about 1843, and in 1859, upon the organization of the colony of Vancouver Island, the place became its capital. In 1866 this colony was annexed to British Columbia, and Victoria became the capital of the united colony.

VICTORIA. See Hong Kong.

VICTORIA (Victoria Alexandrina), queen of Great Britain and Ireland and empress of India, born at Kensington palace, May 24, 1819. She is the sixth sovereign of the house of Hanover, and is the only child of Edward, duke of Kent, fourth son of George III., and the princess Victoria Mary Louisa of Saxe-Coburg-Saalfeld, relict of the hereditary prince of Leiningen. Her father died Jan. 23. 1820. Neither George IV. nor his brothers, the dukes of York and Clarence, had surviving legitimate issue, and she became heir presumptive to the throne on the accession of her uncle William IV. in 1830. Her education was intrusted to the duchess of Northumberland. On the death of William IV. without issue, June 20, 1837, the crowns of England and Hanover, which had been worn by the same person since the accession of George I. (1714), were separated, the former devolving upon the princess Victoria, and the latter, by virtue of the Salic law, falling to the duke of Cumberland, the late king's younger brother. Queen Victoria was crowned in Westminster abbey, June 28, 1838. When she came to the throne the whig ministry of Lord Melbourne was in power. Her sympathies were with that party, and they retained the administration, in spite of a majority against them in the commons, till 1841. The first years of the queen's reign were disturbed by the rebellion in Canada, the anti-corn-law league, the chartist agitation, the Jamaica question, Irish affairs, the Afghan war (1839–'42), and the war with China (1840). The revenue at the same time was steadily falling off, the deficit in 1841 being about £2,000,000. On Feb. 10, 1840, Queen Victoria was married to her cousin Prince Albert of Saxe-Coburg-Gotha. On Aug. 30, 1841, Lord Melbourne resigned, and was succeeded by Sir Robert Peel, who retained office till 1846. He succeeded in placing foreign affairs on a satisfactory footing, and carried through the introduction of an income tax and the abolition of the corn laws. The ministry of Lord John Russell (1846–'52) carried the empire safely through the Irish famine and the dangers of the year of revolutions (1848), and repealed the navigation laws (1849). The conservatives held office under Lord Derby through 1852, and were succeeded by the Aberdeen coalition ministry. Forced to give way before the pressure of public opinion on the question of the management of the Russian war, they were followed, in February, 1855, by the Palmerston ministry, who brought to a successful close the Russian war, as well as wars with Persia and China, and were struggling with the great Indian rebellion when, in February, 1858, they were defeated on a bill to punish conspiracies against foreign potentates, and resigned. Lord Derby held office till June, 1859, when Lord Palmerston was reinstated. The rebellion in India having been put down, the possessions of the East India company were transferred to the crown in August, 1858. The friendly relations which had long existed with Napoleon III. were maintained, and neutrality preserved during the Italian war, the civil war in the United States, the Polish insurrection, and the war in Schleswig-Holstein, though decided leanings on the part of the Palmerston ministry more than once threatened serious complications. The expedition against Mexico (1861) was soon abandoned, and the protectorate over the Ionian islands was given up (1863). Lord Palmerston died in October, 1865, when the ministry was remodelled under Earl Russell. It was defeated on a clause in the reform bill in June, 1866, and gave place to a conservative ministry formed by Lord Derby, which carried a reform bill through parliament in 1867. Lord Derby resigned in February, 1868, and Mr. Disraeli became prime minister. The Abyssinian expedition, begun under Derby, was successfully carried out. There being a majority against Disraeli in the elections of 1868, he resigned in December of that year. Mr. Gladstone was called to the premiership, and held office till the elections of 1874 showed the conservatives again in the majority. The leading events of his administration were the disestablishment of the Irish church, the Irish land act, the elementary education act, the abolition of purchase of army commissions, the negotiation of the treaty of Washington covering the Alabama claims, the passage of the ballot act, and the Ashantee war. He was succeeded in 1874 by Mr. Disraeli, who is still (1876) prime minister. One of his most striking acts of foreign policy was the purchase of the shares of the Suez canal stock belonging to the khedive of Egypt (November, 1875). From the day of her accession to the throne Queen Victoria has enjoyed to the fullest extent the respect and affection of her subjects; yet several attempts have been made to assassinate her: one in June, 1840, by a crazy lad named Oxford; another in May, 1842, by John Francis, who was sentenced to be hanged for the offence, but the sentence was commuted to transportation for life; and a third in July of the same year, by one J. W. Bean, whose only punishment was 18 months' imprisonment. Queen Victoria travels frequently both in her own dominions and abroad. Her mother, the duchess of Kent, died March 16, 1861, and the prince consort Dec. 14 the same year. Her grief at his death has been so intense as in a great degree to prevent her from appearing in public and at court ceremonials, though she has never neglected her duties as a sovereign. She lives in comparative seclusion, and generally spends the summer at Balmoral in Scotland. In February, 1876, she opened parliament in person for the first time since her bereavement; and in April she was authorized by an act of parliament proposed by Mr. Disraeli to assume the title of empress of India. The queen has had nine children, all of whom are living: Victoria, born in 1840, married in 1858 to the present crown prince of Prussia and of the German empire; Albert Edward, prince of Wales, 1841, married in 1863 to the princess Alexandra of Denmark; Alice, 1843, married in 1862 to Prince Louis of Hesse-Darmstadt; Alfred, 1844, created duke of Edinburgh in 1866, and married in 1874 to the grand duchess Maria, only daughter of the emperor Alexander II. of Russia; Helena, 1846, married in 1866 to Prince Christian of Schleswig-Holstein-Sonderburg-Augustenburg; Louise, 1848, married in 1871 to the marquis of Lorne; Arthur, 1850; Leopold, 1853; and Beatrice, 1857.—See "The Early Days of His Royal Highness the Prince Consort," compiled under the direction of the queen by Lieut. Gen. C. Grey (1867); "Leaves from the Journal of our Life in the Highlands" (1868), in which she was assisted by Sir Arthur Helps; and "Life of the Prince Consort" (1874), prepared under her direction by Theodore Martin.

VIDA, Marco Girolamo, an Italian poet, born in Cremona about 1485, died at Alba, Sept. 27, 1566. He studied at Padua and Bologna, and entered the order of the canons of St. Mark at Mantua. Subsequently he became canon of St. John Lateran in Rome, and prior of San Silvestro at Frascati, and in 1532 bishop of Alba. He was one of the most learned scholars and best Latin poets of his day. He wrote also in Italian. His best production is a metrical treatise *De Arte Poetica* (Rome, 1527), which, as well as his *Christias*, has been translated into English. His poem on chess, *Scacchiæ Ludus*, was translated by Goldsmith.

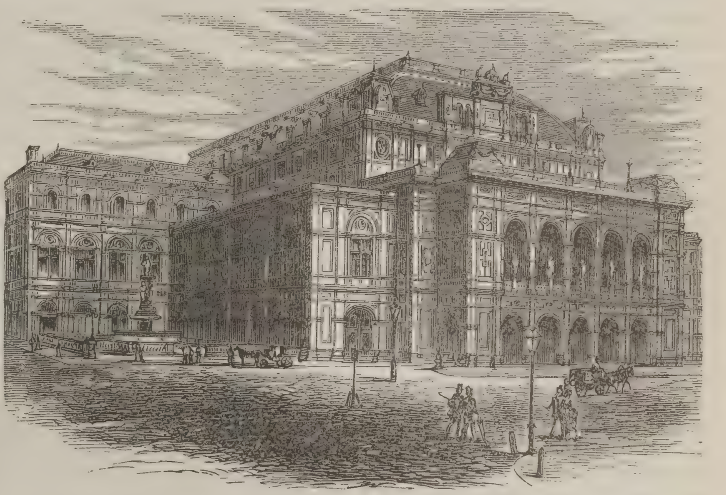
VIDIUS, Vidus, the Latinized name of GUIDO GUIDI, an Italian physician, born in Florence about 1500, died in Pisa, May 26, 1569. Early in life he was called to France, where he was appointed first physician to Francis I., and acquired great reputation both as a practitioner and as a lecturer. After the death of Francis I. he returned to Italy, where he became physician to Cosmo de' Medici, a member of the Florentine academy, and finally professor of medicine in the university of Pisa. His name is perpetuated in the anatomical designation of the Vidian nerve, a filament running from the spheno-palatine ganglion of the sympathetic at the base of the skull, backward through a special canal in the pterygoid bone, and connected by a double branch with the petrous portion of the facial nerve and the carotid plexus of the sympathetic. Vidius published many works on the institutes of medicine, hygiene, therapeutics, fevers, aliment, materia medica, and anatomy. They were all collected by his nephew of the same name, physician to the queen of France (3 vols., Venice, 1614).

VIDOCQ, Eugène François, a French detective, born in Arras, July 23, 1775, died in Paris, May 10, 1857. He began life as a baker, and early became the terror of his companions by his athletic frame and violent disposition. At the same time he was a notorious thief, and after many disgraceful adventures turned up as a soldier, and then as a spy. He was imprisoned at Arras at the instance of the terrorist Lebon, whose sister he married after his release. He accused her of faithlessness, enlisted in the army, and in 1796 returned to Paris with some money, which he soon squandered. Next he was sentenced at Lille to eight years' hard labor for forgery, but repeatedly escaped; and in 1808 he became connected with the Paris police as a private detective. His antecedents enabled him to render important services, and he was appointed chief of the *brigade de sûreté* (safety brigade), chiefly composed of reprieved convicts and others of similar character, which purged Paris of the many dangerous classes. In 1818 he received a full pardon, and his connection with this service lasted till about 1828, when he settled at St. Mandé as a paper manufacturer. Soon after the July revolution he became a political detective, but with little success. In 1836 he opened an office to aid in the recovery of stolen property, but it was closed by the police, and he narrowly escaped imprisonment. In 1848 he was again employed under the republican government, but he died penniless. Many works which he did not write appeared under his name, including *Les vrais mystères de Paris* (7 vols., Paris, 1844), and *Les chauffeurs du nord* (5 vols., 1845-'6); some authorities also deny his authorship of his *Mémoires* (4 vols., 1828; English translation, London, 1828). The best sketch of Vidocq is by M. B. Maurin (Paris, 1858).

VIEL-CASTEL. I. Horace de, count, a French author, born about 1797, died Oct. 1, 1864. He first published a *Collection de costumes, armes et meubles* (3 vols., Paris, 1826; 2d ed., 1834), and afterward many novels of fashionable life, including *Madame la duchesse* (1836), *Gérard de Stolberg* (1837), *Mlle. de Verdun* (1838), and *La noblesse de province* (4 vols., 1841-'2). He also produced several volumes relating to Marie Antoinette (1858-'9), and *Les travailleurs de* 1792, consisting of documents relating to the reign of terror (1862). **II. Louis de,** baron, a French historian, brother of the preceding, born Oct. 14, 1800. He was employed in the foreign office from 1818 to 1821; in the latter year he was attached to the legation at Madrid, and in 1828 to that at Vienna. In 1829 he became subdirector of the political department in the foreign ministry, retired in 1830, but held the office again from 1831 to 1848; and from 1849 till the *coup d'état* of Dec. 2, 1851, he was director. In 1853 he retired from public service and began to prepare his *Histoire de la restauration* (17 vols., 1860-'76; still in progress). His other works include *Essai historique sur les deux Pitt* (2 vols., 1846).

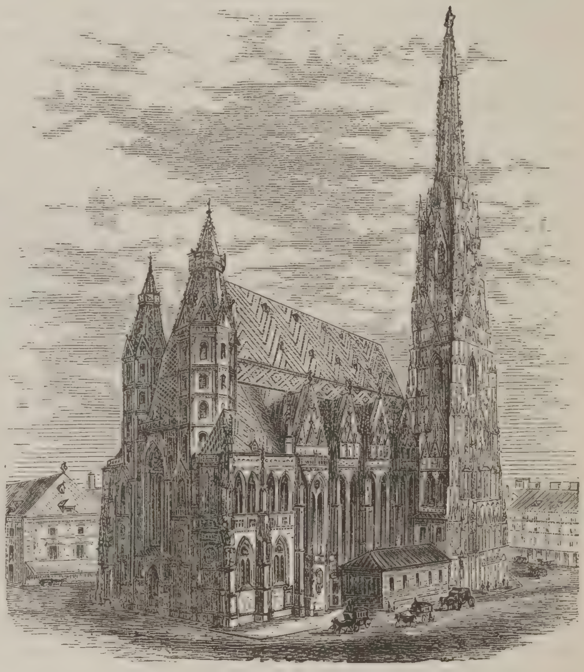
VIEN, Joseph Marie, a French painter, born in Montpellier, June 18, 1716, died in Paris, March 27, 1809. His "Plague of the Israelites in the Time of David" gained him the grand prize of the French academy in 1743, and a pension from the government, enabling him to spend six years at Rome. In 1754 he was elected to the French academy, and in 1775 became director of the French school of art at Rome, and in 1781 of the academy in Paris. Under Napoleon I. he was a senator. He was regarded as the first historical painter of his time, and the regenerator of painting in France. His veneration for the antique had a decided influence upon the works of his pupils David, Vincent, and others. Among his best paintings are "St. Denis preaching to the Gauls," "The Sleeping Hermit," "St. Louis intrusting the Regency to Blanche of Castile," "Hector inciting Paris to arm for the Defence of Troy," "The Parting of Hector and Andromache," "Briseïs in the Tent of Achilles," "Cupid and Psyche," "The Resurrection of Lazarus," and "The Virgin attended by Angels."

VIENNA (Ger. *Wien*), a city of Europe, capital of the Austro-Hungarian monarchy and of the province of Lower Austria, on the Danube, 330 m. S. S. E. of Berlin; lat. 48° 13′ N., lon. 16° 23′ E.; pop. in 1870, 834,284; in 1875, 1,020,770, of whom 673,865 were in Vienna proper and 346,905 in the *Vororte* or communes included in the police districts, but not in the municipal jurisdiction. There are about 25,000 Protestants, 45,000 Jews, and some members of the Greek and other churches; upward of nine tenths of the inhabitants are Roman Catholics. The city is situated in a fertile plain bordered by the Wienerwald, consisting of spurs of the Styrian Alps. About 5 m. N. W. of Vienna the Danube divides into two unequal branches, the southern and smaller of which, called the Donaukanal, after traversing the city, rejoins the main stream a few miles below. The Donaukanal receives the small river Wien and the Alser and Ottakringer creeks. The circuitous subdivisions of the northern arm have been led into a new channel, nearer to the city, about 4 m. long and 300 yards wide, which was opened to navigation on May 30, 1875. This partially obviates the dangers of inundation, from which the lower parts of the city have often suffered, and facilitates its extension in a northeasterly direction. The Donaustadt is here being laid out. Five bridges, two of them for railways, have been constructed across the new bed of the Danube. The finest of the 14 bridges over the Wien is the Elisabethbrücke.—Vienna is one of the most attractive capitals of Europe, and has been greatly embellished since 1858. Until then high walls and deep trenches surrounded the old "city" and divided it from the 36 so-called suburbs (*Vorstädte*). With the levelling of the fortifications the distinction between city and suburbs ceased, and Vienna was divided into nine districts, viz.: Innere Stadt, Leopoldstadt, Landstrasse, Wieden, Margarethen, Mariahilf, Neubau, Josephstadt, and Alsergrund. All but the second are on the right bank of the Danube. The Innere Stadt, still called "the city," comprises the oldest part of Vienna, the largest squares and most notable edifices, and the new and beautiful quarter which has risen on the site of the fortifications and the broad glacis which encircled them. The Ringstrasse, a series of boulevards lined with palatial buildings and planted with trees, forms a belt around this part of Vienna, 2⅔ m. long and 186 ft. wide. Parallel with it runs the Lastenstrasse, for the accommodation of the heavy traffic; and a third belt, the Gürtelstrasse, runs along the low ramparts thrown up in the beginning of the 18th century, marking the limits of the municipal territory. The area thus included has a circumference of 16 m., and contains about 11,000 houses. The *Vororte* gradually assume a rural character toward the surrounding hills and along the shores of the Danube. The streets of Vienna are well paved and kept in good condition, though in the old parts they are mostly narrow and irregular. The Ringstrasse and the almost equally fine streets crossing it constitute the favorite quarter of the wealthy. The new opera house, in this locality, is magnificent in its internal arrangements, and is one of the most beautiful theatres in Europe. The palaces of the archdukes Wilhelm and Ludwig Victor are imposing specimens of the renaissance style, and the gymnasium is a conspicuous Gothic building. Other prominent edifices on or near the Ringstrasse are the new academy of fine arts, the conservatory of music, the museum of arts and industry, the cen-



Opera House.

tral telegraph office, and the military headquarters. Among edifices in course of erection (1876) are a Gothic town hall, the new parliament and university buildings, the imperial museums, the imperial theatre, and the exchange. The fine Francis Joseph quay is the continuation of the Ringstrasse along the Donaukanal. Remnants of the old bastions have been preserved to support prominent structures, such as the palaces of the archduke Albrecht and the duke of Coburg, and the colossal Francis Joseph barracks. The wings of the last are connected by the Francis Joseph gate, one of the few remaining gates. The Jägerzeile in the Leopoldstadt, leading to the Prater, is a broad and animated thoroughfare, and there is at least one similar main street in each of the other districts, among the prominent structures of which are the Belvedere palace, built by Prince Eugene of Savoy, with a fine public garden, the great arsenal, and the station of the Northern railway, one of the finest in the world. The most important square is the Stephansplatz, with the cathedral and episcopal palace, constituting the centre of Vienna, the Kärntnerstrasse, the Graben, and other leading streets converging here. The large square called Am Hof, the Hoher Markt and Neuer Markt, and most other open spaces contain monuments and fountains. The Josephsplatz has an equestrian statue of Joseph II., and the Schwarzenbergplatz one of Field Marshal Schwarzenberg; and on the Schillerplatz the foundation of Schiller's monument was laid, May 9, 1875. On the outer Burgplatz (palace square), the largest in Vienna, are the equestrian statues of Prince Eugene and the archduke Charles. The Burgthor (palace gate), consisting of 12 Doric columns, is also here. The inner Burgplatz or Franzensplatz is formed by the four principal wings of the imperial palace. The easternmost, the Schweizerhof, dates from the 13th century; the northern, the most recent, was erected in 1728; the Amalienhof in the west dates from the 16th century; and the southern wing, containing the largest apartments, was completed in 1670. The monument of Francis I. stands in the middle of the Franzensplatz, and there are four groups representing the labors of Hercules at the portals of the northern wing. Adjoining the palace are the imperial theatre (*Burgtheater*), the riding school, considered the finest in Europe and the scene of splendid pageants, the imperial library, the museums of natural history, and the cabinet of coins and antiquities.—Vienna possesses about 60 Catholic churches and chapels, three Protestant and three Greek churches, and several synagogues. The cathedral of St. Stephen is one of the most magnificent specimens of Gothic architecture. The present edifice dates mainly from the 14th century. Its length is 354 ft., breadth 230 ft., height of nave 89 ft. The great southern tower, completed early in the 15th century, and renovated in 1860–'64, is about 470 ft. high. The cathedral contains nearly 40 marble altars; a pulpit by Anton Pilgram, rich in delicate carvings; and numerous monuments, of which that of the emperor Frederick III., with over 200 figures, is the most remarkable. Underneath the cathedral are vast catacombs. The church of Maria Stiegen, completed early in the 15th century, is another beautiful Gothic structure. The church of St. Peter is modelled after St. Peter's at Rome, and the church of St. Charles, completed in 1737, has an imposing cupola. The Augustinian church contains Canova's mausoleum of the archduchess Christine, and in the Capuchin church is the burial vault of the imperial family. The Votivkirche, begun in 1856 to commemorate the emperor's escape from assassination (1853), will be one of the finest of modern Gothic edifices. Among other notable places of worship are a Greek church and the new Jewish synagogue in the Moorish style. The Mekhitarist Armenian convent at Vienna is next in importance to the main establishment at Venice.—In the imperial palace is the chamber of treasures, in-



St. Stephen's Cathedral.

cluding the largest known emerald; the Florentine diamond of 133 carats, lost by Charles the Bold in one of his battles with the Swiss; the regalia used at the coronation of the German emperors, said to have been taken from the tomb of Charlemagne; Benvenuto Cellini's celebrated salt cellar; and many objects of historical interest. The cabinet of coins and antiquities contains over 140,000 coins and a large collection of cameos and intaglios, vases, bronzes, and gems. The imperial cabinets of zoölogy and botany and of mineralogy are almost unrivalled in completeness. An oriental museum was opened in 1875. In the armory of the arsenal is a curious collection of trophies of war. The miscellaneous Ambras collection in the Belvedere derives its name from a castle in Tyrol, whence it was transferred to Vienna. Connected with it is a museum of Egyptian antiquities. The Belvedere contains the imperial picture gallery, with over 2,000 paintings by almost all the great masters. The collections of Prince Liechtenstein, Count Harrach, and other noblemen, and the academy of fine arts, also abound in remarkable works. The imperial library, founded in 1440, has about 600,000 volumes, 20,000 manuscripts, and 300,000 engravings. The university library, founded in 1777, has 160,000 volumes; that of the archduke Albrecht contains a superb collection of engravings and drawings. The collection of manuscripts in the oriental academy is probably the richest in the world. Valuable libraries of from 10,000 to 80,000 volumes are attached to scientific institutions and convents, and to several private palaces. The university of Vienna, founded in 1365, enjoys a world-wide celebrity for the excellence of its medical school. In the summer term of 1875 the university had 3,919 students, of whom 32 were from the United States. The number of instructors in the winter term of 1875–'6 was 210. Astronomical and meteorological observatories, a botanic garden, and various museums and institutions are connected with the university. The Josephinum, an academy for the instruction of army surgeons, long famous for its anatomical preparations in wax, was recently closed. The polytechnic institute has extensive chemical, physical, and technological collections. In 1868 it was attended by 600 students, and in 1875 by 1,300. An agricultural college was founded in 1872. The academy of sciences, the geological institute, and the military geographical institute all occupy a high rank. The oriental academy prepares candidates for the diplomatic service in the East. The Theresianum, formerly accessible only to the aristocracy, now admits all classes. Among government institutions, the imperial printing office, a vast establishment, is in some respects unrivalled in its appliances. There are five gymnasiums, four *Realgymnasien*, eight *Realschulen*, more than 100 elementary public schools, and many special schools. The city devotes a capital of over 18,000,000 florins to charitable institutions, which are numerous and admirably managed. The general hospital accommodates 3,000 patients; in the connected lying-in hospital more than half of the illegitimate births (10,615 out of a total of 27,265 in 1874) take place, the surrounding country largely contributing to the number.—Vienna swarms with coffee houses, beer gardens, and other public resorts. The Prater, the principal promenade, is a fine park on an island in the Danube, over 5 m. long. It contains six principal avenues, one of which is chiefly frequented by fashionable people with elegant equipages; but the avenues leading to the so-called Wurstelprater, with panoramas, swings, bands of music, and rustic kitchens, are more animated, and their gay aspect is enhanced by the varied costumes of the Austrian nationalities, as well as of Servians, Greeks, and Turks. The great exhibition, opened in the Prater May 1, 1873, was visited by about 5,500,000 persons. The rotunda, the central portion of the main building, has been preserved. (See Industrial Exhibitions.) Among other open-air resorts are the Volksgarten, with Canova's group of "Theseus vanquishing the Centaur," in a temple designed after that of Theseus at Athens; the city park on the Ringstrasse, with the Schubert monument; and the botanic garden. There are eight theatres, besides the new opera house. The Burgtheater is the best in Germany; the Carltheater is patronized by all classes; while the most popular with the masses are the Josephstädter Theater and the Volkstheater in the Prater, in which last plays in the Viennese dialect are performed.—The elevation of the city near its centre is about 500 ft. above the sea. The climate is changeable and unhealthful; the average temperature of the year is 52°, of summer 70°, and of winter 32°. In spring and autumn the city is exposed to high winds, and pulmonary diseases prevail. The annual death rate is about 36 in 1,000. Vienna is supplied with excellent water from the Schneeberg, 40 m. distant, by an aqueduct completed in 1873, the most important modern work of the kind in continental Europe. The city is an emporium for the trade with the East. The principal articles of manufacture are fancy leather, mother-of-pearl and meerschaum articles, jewelry, kid gloves, clocks, musical and optical instruments, shawls, silks, and velvets. In the first half of 1875 the exports to the United States amounted to about 1,400,000 florins; they consisted chiefly of mother-of-pearl and horn buttons, leather, hides, furs, musical instruments, pipes, and kid gloves. The number of banks was reduced by the recent financial crisis from 69 in 1873 to 26 in 1875. Vienna is the centre of an important railway system. It communicates by steamboat with Linz and Pesth, but the shipping is inconsiderable. Horse railways cross the city in all directions. —The immediate surroundings offer charming scenery. The heights of the Leopoldsberg and Kahlenberg (see KAHLENBERG) command a view extending to the Styrian Alps on the south and the Carpathians on the east. The famous gardens of Schönbrunn, the summer residence of the emperor, about 3 m. S. W. of the city, are laid out in the formal style of the last century; they contain a menagerie and a botanic garden, with an extensive collection of tropical plants. The castle of Laxenburg, 9 m. S. of Vienna, possesses many curious relics of feudalism, and is surrounded by a fine park. Near by is the romantic Brühl valley, with the ruins of ancient strongholds. A few miles further S. is Baden, with celebrated sulphur springs, which were known to the Romans.—Vienna, originally probably a Celtic settlement, is first mentioned in history, under the name of Vindobona, as a station of the Roman legions in Upper Pannonia. It rose to strategic importance in the 2d century A. D., but was abandoned by the Romans after the incursion of the Huns in the 5th, and was successively occupied by the Longobards and Avars. It was the principal city of the Ostmark, founded by Charlemagne, and in 1160 became the residence of the dukes of Babenberg. The crusades contributed to its commercial development, and under the early Hapsburg rulers the city attained great prosperity. In the 15th century Æneas Sylvius, afterward Pope Pius II., testifies to the riches of Vienna and the fame of its university. The population was then 50,000. It was captured by Matthias Corvinus in 1485, and heroically defended against Sultan Solyman the Magnificent in 1529. Under Ferdinand I. it became the seat of the German emperors. In the 16th and 17th centuries it was strongly fortified, but its growth was impeded by religious disturbances during the thirty years' war, by the frightful ravages of the plague in 1679, and by the second invasion of the Turks in 1683, when the valor of Starhemberg and the timely succor of John Sobieski of Poland saved the city. It was greatly embellished under Leopold I., and endowed with institutions of learning by Maria Theresa and Joseph II. A treaty was concluded at Vienna in 1738 between Charles VI. and Louis XV. In 1805 and again in 1809 the city was occupied by the French; in the latter year the peace of Schönbrunn was negotiated, and in 1814–'15 the congress of Vienna was held. During the revolutionary movements of 1848 the city was the scene of serious disturbances, and after a rising in October was taken by Windischgrätz. (See AUSTRIA, vol. ii., p. 146.) On Oct. 30, 1864, peace was concluded at Vienna between Austria and Prussia on one side and Denmark on the other. The opening of the exhibition of 1873 coincided with a great financial crisis. It inflicted upon the government a loss of 14,866,921 florins, the expenditures amounting to 19,123,270 and the receipts to 4,256,349, according to official returns of March, 1876.—**The Congress of Vienna** was a conference of the European powers held after the first fall of Napoleon to carry out the stipulations of the treaty of Paris of May 30, 1814, and to reorganize the political system of the continent. Francis of Austria, Alexander I. of Russia, Frederick William III. of Prussia, and the kings of Denmark, Bavaria, and Würtemberg were present, besides minor princes, and all the European states were represented except Turkey. The foremost diplomatists present were Metternich for Austria, Nesselrode for Russia, Hardenberg for Prussia, Talleyrand for France, and Castlereagh for England. The preliminary discussions opened in September, 1814, and the general acts were signed on June 9, 1815, those relating to the Germanic confederation having been signed the day before. The main results were as follows: Austria was reinstated in her former possessions except the Spanish Netherlands, and kept Salzburg, Venetia (constituting with Lombardy the Lombardo-Venetian kingdom), and Dalmatia. Most of the duchy of Warsaw was erected into a hereditary kingdom for Alexander I. Prussia recovered Posen, and acquired half of Saxony, Swedish Pomerania, Westphalia, and important territories west of the Rhine. The republic of Cracow was created, and placed under the protection of Austria, Russia, and Prussia. Norway was confirmed to Sweden as a compensation for Finland, ceded to Russia in 1809. Holland, to which the Belgian provinces were united, was recognized as a kingdom under the prince of Orange, who for cessions in Germany received Luxemburg. Hanover was erected into a kingdom, and the two Mecklenburgs, Oldenburg, and Saxe-Weimar were constituted grand duchies. Germany, whose great mass of petty states and free cities had been mostly absorbed, was reconstituted into a confederation. Neufchâtel, under Prussian sovereignty, was admitted as a canton of the Swiss confederation, and the neutrality of Switzerland was guaranteed. The former ruling houses were reinstated in Naples, Sardinia, to which Genoa was annexed, Tuscany, and Modena, while Parma was assigned to the ex-empress Maria Louisa. The papal see recovered nearly the whole of its possessions, France retaining Avignon and Venaissin. The latter power was restricted to very nearly the same territory that it had possessed before the revolution. England retained Cape Colony and Mauritius, which had belonged respectively to Holland and France, as well as Malta and Heligoland, and relinquished her other conquests. The Ionian islands were declared an independent republic under British protection. The conclusion of the treaties, which had been delayed both by extravagant festivities and political intrigues, was hastened by the sudden return of Napoleon from Elba. The last coalition against him was immediately formed (March 25, 1815), and a few days after the signing of the treaties the battle of Waterloo was fought.

VIENNE, a W. department of France, formed chiefly from the old province of Poitou, bordering on the departments of Maine-et-Loire, Indre-et-Loire, Indre, Haute-Vienne, Charente, and Deux-Sèvres; area, 2,691 sq. m.; pop. in 1872, 320,598. It is level, excepting in the south. The principal rivers are the Vienne, Charente, Gartempe, and Creuse. About one third of the area is arable, one eighth covered with forests, and the remainder waste. The vine is extensively cultivated, but yields only inferior wines. Chestnuts form an important part of the food of the peasantry. Sand of a superior quality for making glass and imitation diamonds is procured from Vienne, and there are excellent quarries of lithographic stone and mill stones, and iron mines. Lace, woollen goods, iron ware, saddlery, firearms, and cutlery are made. It is divided into the arrondissements of Châtellerault, Civray, Loudun, Montmorillon, and Poitiers. Capital, Poitiers.

VIENNE (anc. *Vienna*), a town of Dauphiny, France, in the department of Isère, on the left bank of the Rhône, at the mouth of the Gère, 49 m. N. W. of Grenoble; pop. in 1872, 26,017. The cathedral of St. Maurice and St. Peter's are the most interesting churches. The college dates from 1605. The abbey of St. Peter is now a museum for the Roman antiquities which abound here, including remains of aqueducts and an amphitheatre, and a well preserved temple dedicated to Augustus and Livia.—Vienne was the capital of the first and second kingdoms of Burgundy. The 15th general council was held here in 1311–'12.

VIENNE, Haute. See HAUTE-VIENNE.

VIERSEN, a town of Rhenish Prussia, in the district of Düsseldorf, near the Niers and the Nordkanal, 10 m. S. W. of Crefeld; pop. in 1871, 18,550. It is an important centre of cotton, flax, woollen, silk, ribbon, and velvet manufactures, employing 10,000 persons.

VIETA, or **Viète, François,** a French mathematician, born at Fontenay-le-Comte in 1540, died in Paris in December, 1603. He was master of requests during the reigns of Henry III. and Henry IV. He was once saved from imprisonment and death by the duchess de Rohan. For Henry IV. he deciphered the communications made by the Spaniards with one another, through a cipher composed of more than 500 characters signifying different things at different times. He was the first to combine symbols of operation with symbols of quantity, and thus to render algebra a purely symbolical science. An edition of most of his works was published at Leyden in 1646, edited by Van Schooten.

VIEUSSENS, Raymond, a French physician, born in the district of Rouergue in 1641, died in Montpellier about 1720. His most important title to distinction rests upon his *Neurographia Universalis* (Lyons, 1685), on the anatomy of the brain, spinal cord, and nerves. Among other anatomical structures first described by him is the "valve of Vieussens," a thin layer of white nervous matter forming the roof of the anterior part of the fourth ventricle of the brain, and still known by his name. His last publication was his *Traité des liqueurs du corps humain* (Toulouse, 1715).

VIEUXTEMPS, Henri, a Belgian violinist, born in Verviers, Feb. 20, 1820. He is the son of a tuner of instruments, played the violin in public at the age of eight years, was a pupil of De Bériot for several months, studied composition under Reicha, appeared with success in Paris and Vienna in 1830, and spent several years in professional journeys through Europe, becoming a public favorite, especially at St. Petersburg and Moscow. In 1843, 1855, and 1870 he visited America, on the last occasion being associated with Mlle. Nilsson in concerts. His playing is distinguished by great energy and breadth, with remarkable elegance and correctness. His compositions combine the qualities of classical and modern music.

VIGILIUS, pope, born in Rome, died in Syracuse in 555. While yet a deacon he was designated by Pope Boniface II. (530–'32) as his successor in the papal see; but this act was repealed as uncanonical. During the pontificates of Agapetus I. and Sylverius, Vigilius was *apocrisiarius* or papal envoy at Constantinople. He sided with the imperial government against Pope Sylverius, and was sent to Rome to procure his imprisonment and exile. This being accomplished, Vigilius was proclaimed pope in 537, but is considered to have been an antipope till 540, when Sylverius died. Among many letters of doubtful authenticity is one said to have been written by Vigilius in 538, at the request of the empress Theodora, to the heads of the Monophysites, in which he approved of their views, and condemned the anti-Monophysite decisions of Pope Leo I.; but later (after 540) he refused to favor the Monophysites. For the course afterward adopted by this pope in the Monophysite controversy see CONSTANTINOPLE, COUNCILS OF.

VIGNOLA, Giacomo Barozzio da, an Italian architect, born at Vignola, in Modena, in 1507, died in Rome in 1573. He studied painting with the Passarotti at Bologna, but subsequently turned his attention to architecture, which he studied at Rome. After spending two years in France with Primaticcio, he went to Bologna, where he constructed several fine palaces and public buildings, and finally settled in Rome. He was appointed papal architect by Julius III. in 1550, and designed the church of the Jesuits in Rome, the Caparola palace, and the two lateral cupolas of St. Peter's, of which he became architect after the death of Michel Angelo. He also furnished the plans for the reconstruction of the palace of the Escurial in Spain. Vignola's works on "The Five Orders of Architecture" and "Practical Perspective" are still among the best authorities on those subjects.

VIGNY, Alfred Victor de, count, a French poet, born at Loches, Touraine, March 27, 1799, died in Paris, Sept. 18, 1863. He studied in Paris for a time, till his legitimist mother, fearing the ascendancy of Napoleon over her son's imagination, had him educated at her château by a private tutor. In 1816 he became a sub-lieutenant in the royal guard, and in 1823 a captain. In 1827, subsequent to his marriage at Paris with Lydia Bunbury, an English lady, he retired from service. He had been known since 1822 as a poet of superior genius, though his popularity with the romantic school and the masses of readers dated only from his historical romance *Cinq-Mars, ou une conjuration sous Louis XIII.* (2 vols., Paris, 1826), which had many editions and translations. He achieved a still more brilliant though not lasting success by his drama *Chatterton*, first performed in 1835 at the Théâtre Français. His relation with Mme. Dorval, the celebrated actress, who excelled as Kitty Bell in this play, and other irregularities of his life, caused great unhappiness to his wife. In 1845 he was elected to the academy. His earliest poetical works, *Héléna*, *La fille de Jephté*, *La femme adultère*, &c., were included in his *Poëmes* (1822). *Éloa, ou la sœur des anges*, *Le déluge*, *Moïse*, and *Dolorida*, included in his *Poëmes antiques et modernes* (1824–'6), are his finest and most original productions. In 1832 appeared his prose work *Stello*, and in 1835 *Servitude et grandeur militaire.* He also translated "Othello," and wrote *La maréchale d'Ancre*, a play entirely eclipsed by *Chatterton.* Ratisbonne edited his posthumous *Les destinées* (1864). A new edition of De Vigny's complete works appeared in 8 vols. (1863–'6).

VIGO, a W. county of Indiana, bordering on Illinois, and drained by the Wabash river; area, 400 sq. m.; pop. in 1870, 33,549. The surface is level or undulating and diversified with forests and prairies, and the soil is very fertile. Bituminous coal, limestone, and freestone abound. It is intersected by the Wabash and Erie canal, and by several railroads meeting at Terre Haute. The chief productions in 1870 were 354,132 bushels of wheat, 832,372 of Indian corn, 96,179 of oats, 144,319 of potatoes, 316,076 lbs. of butter, 56,637 of wool, and 13,950 tons of hay. There were 7,206 horses, 4,767 milch cows, 6,688 other cattle, 19,009 sheep, and 23,118 swine. The number of manufactories was 213; capital invested, $1,279,555; value of products, $4,102,154. The chief establishments were 5 for the manufacture of carriages and wagons, 2 of cars, 10 of bricks, 19 of cooperage, 2 of hubs and wagon material, 5 of iron, 4 of machinery, 2 of woollens, 10 flour mills, 1 distillery, 6 breweries, and 16 saw mills. Capital, Terre Haute.

VIGO, a seaport town of Spain, in the province and 15 m. S. of the city of Pontevedra, beautifully situated in a fertile region on the S. shore of the bay of Vigo; pop. about 8,000. It has old walls and suburbs, steep streets, extensive lazarettos, a harbor accessible to small craft, and a roadstead sheltered by hills and protected by fortified castles, where the English and French steamers to South America anchor. The annual imports, chiefly grain and oil, amount to about 20,000,000 reals, and the exports, including wine, fish, &c., to 7,000,000. The English, under Sir Francis Drake, repeatedly ravaged the place toward the close of the 16th century. On Oct. 23, 1702, the allied English and Dutch squadron destroyed the Spanish galleon fleet and French convoys off Vigo; and the English captured the town in 1719.

VILAYET, the designation of the chief administrative divisions or provinces of the Ottoman empire, each under the authority of a governor general (*vali*) and a council. The vilayets are divided into livas or sanjaks, under governors appointed by the Porte, but receiving their instructions through the governors general, and these into cazas or districts. Some of the Turkish provinces were until recently governed by pashas, and hence also called pashalics; but this name has been replaced by the term vilayet or its equivalent *eyalet* (government), which two terms are used more or less indiscriminately.
